rich valley of the Ili. We then trace him to the Chu, over this river to Talas and the Tashkent region, and over the Jaxartes (or Syr Daria) to Samarkand, where he halted for some months. Finally, through the "Iron Gates" of Termit, over the Oxus, and by way of Balkh and northern Afghanistan, Chang Chun reached Jenghiz' camp near the Hindu Kush. Returning home he followed much the same course as on his outward route: certain deviations, however, occur, such as a visit to Kuku-khoto. He was back in Peking by the end of January 1224. From the narrative of his expedition (the *Si yü ki*, written by his pupil and companion Li Chi Chang) we derive some of the most faithful and vivid pictures ever drawn of nature and man between the Great Wall of China and Kabul, between the Aral and the Yellow Sea. We may particularly notice the sketches of the Mongols, and of the people of Samarkand and its neighbourhood; the account of the fertility and products of the latter region, as of the Ili valley, at or near Almalig-Kulja; and the description of various great mountain ranges, peaks and defiles, such as the Chinese Altai, the Tian Shan, Mt. Bogdo-ola (?), and the Iron Gates of Termit. There is, moreover, a noteworthy reference to a land apparently identical with the uppermost valley of the Yenisei. After his return Chang Chun lived at Peking till his death on July 23, 1227. By order of Jenghiz some of the former imperial garden grounds were made over to him, for the foundation of a Taoist monastery.

BIBLIOGRAPHY.—See E. Tretschneider, *Mediaeval Researches from Eastern Asiatic Sources*, vol. i. pp. 35–108, where a complete translation of the narrative is given, with a valuable commentary; C. R. Beazley, *Dawn of Modern Geography*, iii. 539. (C. R. B.)

CHANGE, the substitution of one thing for another, hence any alteration or variation, so applied to the moon's passing from one phase to another. The use of the word for a place of commercial business has usually been taken to be a shortened form of Exchange (q.v.) and so is often written 'Change. "Change" is particularly used of coins of lower denomination given in substitution for those of larger denomination or for a note, cheque, etc., and also for the balance of a sum paid larger than that which is due. A further application is that in bell-ringing, of the variations in order in which a peal of bells may be rung (see BELL).

CHANGELING, the term used of a child substituted or changed for another. It was formerly believed that infants were sometimes stolen from their cradles by the fairies before christening, so that in the Highlands of Scotland babies were strictly watched till then. Any specially peevish or weakly baby was regarded as a changeling. The belief is referred to by Shakespeare, Spenser and other authors.

See Pennant, *Tour in Scotland* (1796), p. 257, and W. Wirt Sikes, *British Goblins* (1880).

CHANGE OF LIFE, a popular term for the menopause (q.v.) or climacteric.

CHANGOAN, a tribe or small group of tribes of South American Indians, forming an independent linguistic stock. The Changos occupied the arid coast of the desert of Atacama in northern Chile. They are an almost dwarfish, fisher folk of very simple culture, and are now nearly extinct, except in the vicinity of Cobija. The Changos depended largely on shell-fish for food, and had balsas or rafts of poles and inflated seal-skins from which they fished along the shore. They wore little clothing, and had small crude huts of poles and thatch. Unlike the population of the coast farther north, the dead were buried at length, instead of flexed.

See E. Boman, *Antiquités de la Région Andéenne de la République Argentine et du Désert d'Atacama* (Paris, 1908).

CHANGRA or **KANGHARI** (anc. *Gangra*; called also till the time of Caracalla, *Germanicopolis*, after the emperor Claudius), the chief town of a vilayet of the same name in Asia Minor, situated in a rich, well-watered valley; altitude 2,500 ft. The ground is impregnated with salt, and the town is unhealthy. Pop. (1927) 73,583. Gangra, the capital of the Paphlagonian kingdom of Deiotarus Philadelphus, son of Castor, was taken into the Roman province of Galatia on his death in 6–5 B.C. The earlier town was built on the hill behind the modern city, on which are the

ruins of a late fortress; while the Roman city occupied the site of the modern. In Christian times Gangra was the metropolitan see of Paphlagonia.

Synod of Gangra.—Conjectures as to the date of this synod vary from 341 to 376. The synodal letter states that 21 bishops assembled to take action concerning Eustathius (of Sebaste?) and his followers, who contemned marriage, disparaged the offices of the church, held conventicles of their own, wore a peculiar dress, denounced riches, and affected especial sanctity. The synod condemned the Eustathian practices. The 20 canons of Gangra were declared ecumenical by the Council of Chalcedon, 451.

See Mansi ii. pp. 1095–1122; Hardouin i. pp. 530–540; Hefele 2nd ed., i. pp. 777 sqq. (Eng. trans. ii. pp. 325 sqq.).

CHANG TSO-LIN (1873–1928), Chinese military leader, born in the Province of Fengtien. Of humble origin and without education, he was successively a swineherd, a menial in the Catholic Mission at Newchang and a labourer on the Peking–Mukden Railway. Later he abandoned regular employment and rose to prominence in 1904 as a leader of *Hunghutse*, or Manchurian brigands, when he and his band became irregular allies of Japan during the Russo–Japanese War. After the Treaty of Portsmouth, under Japanese advice, he submitted to the Chinese Government, and he and his following were incorporated in the Chinese army. He received quick promotion, and attained command of a Division. In 1913 he was appointed *Tutuh*, later *Tuchun*, both terms denoting Military Governor, of Fengtien.

Chang Tso-lin faithfully served the young republic of China, and opposed both Yuan Shi-k'ai's monarchical aspirations in 1916 and Chang Hsün's attempted restoration of the Imperial dynasty in 1917. In 1918 he was appointed Inspector-General of the Three Eastern Provinces, i.e., of Manchuria, and, while civil government slowly weakened, his military control became absolute. He adopted the course, unusual in China, of punctually paying, feeding and disciplining his troops, and by this means he became a dominant factor in the unstable politics of the country. In civil life his activities were boundless: mining, farming, stock-breeding, banking, railway construction, in these and many other forms of industrial enterprise, his hand was felt.

During the concluding twelve years of his life, while maintaining autocratic control of Manchuria, he made four descents upon Peking, actuated on each occasion by the desire to set up a stable form of government for the country. In 1920, when, during the halting and incapable Presidency of Hsu Shi-chang, the Government fell under the control of the reactionary militarists known as the Anfu Party, he drove their leaders into retirement, and, in co-operation with Tsao Kun, the Tuchun of Chihli, made an attempt to form an administration. Their efforts were fruitless, and in 1921 he again came to Peking and installed a Cabinet under Liang Shih-yi. Upon this occasion he was defeated by General Wu Pei-fu and driven back to Manchuria, whereupon he declared the independence of the Three Eastern Provinces. His third incursion took place in 1924, when large forces under Wu Pei-fu assembled near the Great Wall to repel the Manchurian invasion. Owing to the treacherous defection of Feng Yu-hsiang, who withdrew to Peking and "declared for peace," Wu Pei-fu's forces collapsed, and Chang's army pressed forward, eventually occupying Shantung, Anhui and Kiangsu. In the latter part of this year he was occupied in suppressing the revolt of one of his lieutenants, by name Kuo Sung-ling, whom he defeated outside Mukden and executed. His final coming to Peking was in December, 1926, when he once more announced his intention to reorganize the Government. In June, 1927, he formed a Cabinet consisting entirely of his own adherents, with Pan Fu as Premier, he himself, under the title of Generalissimo, becoming President. He watched from Peking the victorious Southern Nationalist army reach the Yangtse, and their further advance in 1928 to Peking. His troops, after some show of defending the capital, received orders to stop further opposition, and Chang himself left for Mukden by train on June 3. Before he reached his destination the train was bombed and he succumbed to injuries received.

Soft-voiced and of delicate constitution, suave yet resolute, Chang Tso-lin would have been an admirable viceroy under the

Empress Dowager's régime. It was the only system of government he understood, and his failure to bring about union and a stable government is evidence of how far removed he was *au fond* from realizing the strides which the country had made in acquiring race-consciousness and a political sense. His administrative achievements in Manchuria, and his friendliness towards foreigners, are among his claims to be styled a Chinese patriot.

(W. E. L.)

CHANNEL FERRY. In the World War the necessity of utilizing the canals and waterways of France and Belgium for transport in order to relieve the pressure on the railways was early recognized, and to take over and develop this work behind the British lines the Inland Water Transport Section of the Royal Engineers was formed in 1914.

The activities of this new organization became so great that a similar organization (later the Directorate of Inland Waterways and Docks, Royal Engineers) was set up in England. The functions of this directorate expanded until it took in other branches of transport besides canal traffic, and included the supply and equipment for docks and harbours, and constructional work at various ports which formed bases for transport of munitions and materials for the British armies in all theatres of war.

To meet the growing demands from France for suitable craft, personnel, plant and stores in an efficient and economical manner, it was decided to establish a cross-channel barge port and stores depot, from which barges capable of navigating the French canals could be sent across loaded. Richborough in Kent was chosen.

The site had many advantages. It was:—(a) directly opposite the ports and canals of northern France (*see Map*); (b) within easy access of a main railway system; (c) a flat, low-lying, unoccupied ground of over 2,000 acres, capable of being developed without interfering with any vested interests, or existing traffic

yard where the sorting, storage and dispatch of salvage was carried on by female labour; large store warehouses from which consumable stores, plant, and other material were dispatched overseas at a moment's notice; camp accommodation for 15,000 troops and a regimental depot for the reception, equipment, training and disposal of all personnel recruited for the Inland Waterways and Docks for service at home and in the various theatres of war.

These works were constructed by military labour, especially recruited from skilled trades and working under the supervision of technical officers. The recruits, large numbers of whom were of low medical category, after being given a short military training at the regimental depot were passed on for duty and intensive training to one or other of the formations, *e.g.*, construction, workshops, railway traffic, marine or stores, from which they were drafted overseas for similar service as and when required, 1,200 officers and 51,000 other ranks passing through in this way.

Cross-Channel Barge Service.—The expansion of Richborough into a transportation base and the establishment of the channel barge service—carried on without a break day or night until the Armistice with barges specially designed for the crossing and for navigating the French waterways—was an enormous relief to ordinary shipping and the following advantages were also obtained:—(a) Relief of congestion at French ports as barges passed straight through to inland depots with consequent avoidance of double handling; (b) return of barges from war zone loaded with salvage; (c) saving of railway carriage in France; (d) relief to English ports; (e) disposal of both marine and war risks into smaller units; (f) no naval patrol necessary.

The total exports by barge up to the armistice exceeded 3½ million tons and the total imports of salvage half a million.

A fleet of 386 craft was controlled from Richborough including 67 sea-going tugs and 255 200-ton barges. Over 20,000 cross-channel trips were made and it is interesting to note that no craft was lost as the result of enemy action, though some sustained casualties when in canals close up behind the British lines.

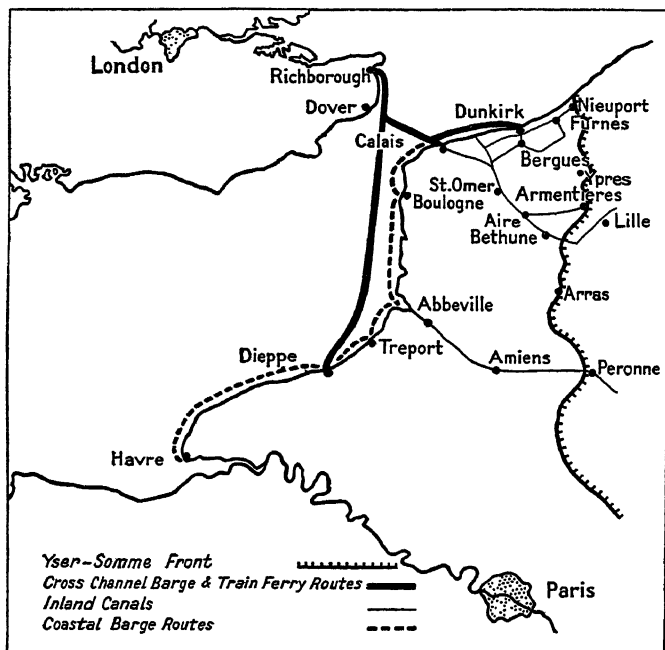

Train Ferry Service.—Late in 1916, the serious shipping position, the increasing demand from France for supplies, and the delays in the channel ports owing to inadequate appliances for handling heavy cargo, led to the decision to establish a train ferry service on the Richborough cross-channel route to enable heavy war material to be run direct on rail from factories to war areas.

In Jan. 1917 orders were placed for three train ferry vessels capable of carrying 54 fully loaded ten-ton trucks or as many guns, tanks, locomotives, or other vehicles as could be arranged on the four deck-tracks, or a total load of 960 tons.

Terminals and berths for these vessels were built at Richborough, Southampton, Dunkirk, Calais and Dieppe; the method of communication between ship and shore being a double track self-adjusting bridge hinged at the shore end.

The service from Richborough to Calais began in February 1918 and was carried on without mishap and without convoy. The vessels were good seaboats and crossed in all but the most severe weather. As a transport unit they were of immense value. Their first cargoes were heavy wagons, 340 of which were taken across in seven trips (averaging 12 hours each). Previously it had taken a 3,600-ton steamer one month to convey 300 wagons. It is estimated that the three ferry boats released six 8,000 ton ocean-going steamers, whilst an enormous economy was effected in the avoidance of double transshipment. One of the outstanding features of the service was the ease and rapidity with which the vessels were loaded and unloaded—the time averaging less than 25 minutes per trip. After the disaster of March 21, 1918, when some 600 British guns were lost, over 700 guns were shipped by train ferry within 48 hours to replace them. In May 1918 two 14-inch guns on railway mountings, each weighing 302 tons and measuring 87ft. overall, were taken over safely and run up to the front without the necessity of dismantling in England and re-erecting in France. In his dispatch of Jan. 7, 1919, F.M. Sir Douglas Haig said, "During the period following the great defensive battles, up to the final triumph of the Allied cause the channel ferry has proved of inestimable value."

After the war, there was much uncertainty as to the future of

MAP SHOWING THE CROSS-CHANNEL BARGE AND TRAIN FERRY ROUTES ESTABLISHED BY THE BRITISH GOVERNMENT DURING THE WORLD WAR TO TRANSPORT MUNITIONS AND STORES TO THE WESTERN FRONT

or other port facilities; (d) situated on a tidal river with a sheltered entrance; (e) comparatively inaccessible to enemy naval raids.

The development of Richborough was remarkably rapid and by 1917—although the primary object of its existence was the cross-channel barge traffic—it had grown into a large and well equipped seaport and workshop base with three-quarters of a mile of wharves and 70m. of railway sidings capable of dealing with 30,000 tons of traffic per week; with extensive engineering workshops and foundries where urgent repair work which could not be carried out in the war areas was done; a spacious salvage transit

this remarkable establishment. Finally the port passed to the control of a powerful industrial group which has large interests in the Kent coalfields, in the development of which it should be a most useful adjunct.

(A. J. A. W.)

CHANNEL ISLANDS, a group of islands in the English Channel (French Îles Normandes), belonging (except the Îles Chausey) to Great Britain. They lie between $48^{\circ} 50'$ and $49^{\circ} 45'$ N., and $1^{\circ} 50'$ and $2^{\circ} 45'$ W., and diagonally from south-east to north-west across the shallow rectangular bay, formed by the west coast of the department of Manche (France) and the north coast of Brittany. This bay is strewn with numerous small islands and rocks, and owing to the concentration of the tidal wave in it has dangerous tidal races. The total land area of the islands is about 75 square m. (48,083 acres), and the population (1931) 93,061. There are four principal islands:—Jersey (area 45 sq.m. pop. 50,455), Guernsey (area 24.5 sq.m. pop. with the following islands 42,606), Alderney (area 3.06 sq.m.), Sark (area c. 2 sq.m.). St. Helier is the chief town of Jersey, St. Peter Port of Guernsey and St. Anne of Alderney: the two first are ports. There is communication by steamer on alternate days in winter, and daily in summer from Southampton and Weymouth with Guernsey and Jersey, and on certain days from French ports, especially from St. Malo with Jersey and Guernsey, and from Cherbourg with Alderney and Guernsey. Communications are maintained locally between the larger islands, which are much visited by tourists.

Structurally, the islands are a partially submerged portion of the Armorican massif, and fall into four groups related to old fold lines running west from the Cotentin Peninsula. The most northerly group, comprising Alderney, Burhou, Ortach, the Casquets and numerous other islets, lies due west of Cape de la Hague. The Casquets, on which has been built a powerful lighthouse, were formerly dangerous to ships, notable wrecks being that of the "White Ship" (according to tradition) in 1120, the "Victory" in 1744, and the "Stella" in 1899. The second, and most westerly group, includes Guernsey with a few islets to the west, and, to the east, Sark, Herm, Jethou (inhabited islands) and others. The straits of Little Russel and Great Russel separate Guernsey and Herm, and Herm and Sark respectively. Sark is famous for its cliffs and caves. Herm has a remarkable shell beach, half-a-mile long, formed in a tidal eddy north of the island. The third group, south-east of the second, and separated from it by La Déroute strait, includes Jersey and a few small islets, of which the Ecréhou to the north-east are the chief. The fourth group consists of the Minquiers lying almost 12 m. S. of Jersey, and the Îles Chausey lying almost 9 m. W. by N. of Granville, in which commune they are included. Maîtresse Île, the largest of the Minquiers, provides landing and shelter to fishermen. Of the Chausey islands Grande Île is permanently inhabited by farmer-fishermen, and the other islets temporarily by fishermen. Sea-weed burning and granite-quarrying also occupy some of the inhabitants. The dominant east-west structural lines of Armorica are broken by north to south lines, a net-work only partially obscuring certain north-east to south-west lines, and in the fine coastal scenery of the islands and in their vertical cliffs, rectangular bays, and intervening channels, we get repeated the structural "pattern" of the whole massif. When the coast stood at the 30 fathom line, the islands formed a projection of the French coast, but before the 20 fathom line had become the coast line the Alderney group had become separate from the continent. Before the 10 fathom line had become the coast the Guernsey group had also been separated. There is only shallow water between the Jersey and Chausey groups and the mainland, and legend ascribes invasions of the sea to Post-Roman times, though this is considered doubtful. Raised beaches of uncertain date are evidence of downward movements beyond the present levels, while there are numerous evidences of submerged forests at St. Ouen's Bay (West Jersey) and Vazon Bay (West Guernsey).

Geology.—Geologically the Channel Islands are closely related to the neighbouring mainland of Normandy. With a few exceptions all the rocks are pre-Cambrian. They consist of massive granites, gneisses, diorites, porphyrites, schists and phyllites; dykes and veins are abundant. In Jersey we find in the north-west corner a

granitic tract extending from Grosnez to St. Mary and St. John, beyond which it passes into a small granulitic patch. South of the granites is a schistose area, by St. Ouen and St. Lawrence, and reaching to St. Aubin's Bay. Granitic masses again appear round St. Brelade's Bay. The eastern half of the island is largely occupied by porphyrites and similar rocks with rhyolites and devitrified obsidians; a complex igneous and intrusive series of rocks lies around St. Helier. In the north-east corner of the island a conglomerate, possibly of Cambrian age, occurs between Bouley Bay and St. Catherine's Bay. Tracts of blown-sand cover the ground for some distance north of St. Clement's Bay and again east of St. Ouen's Bay. The northern half of Guernsey is mainly dioritic, the southern half, from St. Peter, is occupied by gneisses. Several patches of granite and granulite fringe the western coast; the largest of these is a hornblende granite around Rocquaine Bay. Hornblende gneiss from St. Sampson and quartz diorite from Capelles, Corvée and elsewhere have long been transported to England for road metal. Sark is composed almost wholly of hornblende-schists and gneisses, with hornblende granite in North Sark and middle Bréchou and diorite in Little Sark and west Bréchou. In Alderney we have Cambrian grits stretching from Corblets Bay (North-east) to l'Étac à la Quoire (east) overlain by modern sands at Longy, with a small outlier opposite Coque Lihou. The island, west of the main area of grits, is diorite with granite round the coast (hornblende at Crabby and Tourgis, inclining to gabbro at Rozelle, where it is quarried, and fine-grained with rare hornblende and biotite at Bibette Head, Saye Bay and Corblets Bay). The island south and west of a line from Tourgis Point to Noire Roque is granite-porphry faulted against diorite round the coast.

Climate.—The climate is mild and pleasant. In Jersey the mean temperature for twenty years is found to be—in January (the coldest month) 42.1° , in August (the hottest) 63° , mean annual 51.7° . In Guernsey the figures are, for January 42.5° , for August 59.7° , mean annual 49.5° . The mean annual rainfall for twenty-five years in Jersey is 34.21 in., and in Guernsey 38.64 inches. Guernsey has rather less sunshine than Jersey, but both have considerably more than favoured spots on the south coast of England. Snow and frost are rare, but it is often cold in spring. Thick sea-fogs are not uncommon, especially in May and June.

Flora and Fauna.—The flora of the islands is remarkably rich, producing more than 2,000 different species of plants. Timber is scarce, but the evergreen oak, the elm and the beech are common. Root crops are more important than grain. The tomato is a field crop in Jersey and a greenhouse crop in Guernsey. Grapes and peaches ripen in greenhouses without artificial heat and figs out of doors. Such plants as arbutus, camellia, myrtle and magnolia flourish. The Guernsey lily with its rich red petals is said to have come from Japan.

The distribution of animals in the Islands illustrates the later separation of Jersey from the continent, and points also to the northward advance of animals following the retreat of the ice. Thus Jersey has the toad, the grass-snake, the green lizard, the newt and the mole. The mole has reached Alderney and Sark, but not Guernsey. Squirrels, hares and foxes formerly inhabited Jersey, but never Guernsey; Guernsey, in common with the other islands, has the frog, the slow-worm and the rabbit. The red deer was once indigenous, and the black rat is still found in Alderney, Sark and Herm. The birds number over 200 species, the variety of fish is very great, and crustacea, molluscs including *Haliotis*, and zoophytes abound round the coasts.

Government.—For purposes of government the Channel Islands (excluding the Chauseys) are divided into two divisions:—(1) Jersey, and (2) the bailiwick of Guernsey, which includes Alderney, Sark, Herm and Jethou. The constitution of each division is broadly the same. Until 1854 governors were appointed by the crown; now a separate military lieutenant-governor is appointed for each division on the recommendation of the British War Office after consultation with the Home Office. The other crown officials are the bailiff (*bailli*) or chief magistrate, the *procureur du roi*, representing the attorney-general, and the *avocat du roi*, or in Guernsey the *contrôleur* representing the solicitor-

general. In Jersey the *vicomte* is also appointed by the crown, in the position of a high sheriff (and coroner); but his counterpart in Guernsey, the *prévôt*, is not so appointed. The bailiff in each island is president of the royal court, which is composed of twelve jurats, elected for life, in Jersey by the ratepayers of each parish, in Guernsey by the Elective States, a body which also elects the *prévôt*, who, with the jurats, serves upon it. The rest of the body is made up of the rectors of the parishes, the *douzaines*, or elected parish councils ("dozens," from the original number of their members) of the town parish of St. Peter Port, and of its four cantons, and the country parishes, and certain other officials. The royal court administers justice (but in Jersey there is a trial by jury for criminal cases), and in Guernsey can pass temporary ordinances subject to no higher body. It also puts forward *projets de loi* for the approval of the Deliberative States. Jersey and Guernsey have stipendiary magistrates for police matters. Alderney and Sark have a separate legal existence with courts dependent on the royal court of Guernsey. In both Jersey and Guernsey the chief administrative body is the Deliberative States. The Jersey States is composed of the lieutenant-governor (with right of veto, but no vote), the bailiff, jurats, parish rectors, parish *connetables* and deputies, the *procureur* and *avocat* (with right to speak but no vote), and the *vicomte* (with right of attendance only). If the bailiff dissent from any measure, it is referred to the privy council. In Guernsey the States consists of the bailiff, jurats, eight out of ten rectors, the *procureur* and deputies; the lieutenant-governor is invited and may speak. Both States administer local affairs; relations with the British parliament are maintained through the privy council. Acts of parliament are transmitted to the islands by an order in council to be registered in the rolls of the royal court, and are not binding until this is done; registration may be held over pending discussion by the States if any act is considered to menace the privileges of the islands. The right of the crown to legislate by order in council is limited in the same way. In cases of encroachment on property, an ancient form of appeal called *Clameur de Haro* survives (see HARO, CLAMEUR DE). The islands are in the diocese of Winchester, and there are deans in both Jersey and Guernsey, also rectors of a parish.

These peculiar constitutions are of local development, and represent adaptations of Norman feudal schemes to remote communities under lords who in many cases were absentees; views as to the origin of the jurats differ but they are an ancient institution; the practice of summoning the States to assist in the passing of ordinances was established later by the bailiff and jurats, and at last the States claimed the absolute right (confirmed 1771) of being consulted. There is compulsory service in the militia; garrisons of regular troops are maintained; taxation is light in the islands, and pauperism is practically unknown.

In 1925 the revenue of Jersey was £236,586, and its expenditure £247,256; the revenue of Guernsey was £228,864, and the expenditure £266,744. The public debt in the respective islands was £506,375 and £561,744. Crown revenues from Jersey include seigniorial dues and revenues from houses, lands and tithes. For Guernsey there are seigniorial dues and in some cases dues paid on transference of property. From Alderney the Crown receives chiefly harbour dues. These revenues are all small. English coinage is current, but Jersey has a local copper coinage and local one-pound notes. Guernsey also has such notes, and its copper coinage consists of pence, half-pence, two-double and one-double (one-eighth of a penny) pieces.

During the World War the islands provided a large contingent of men, and in 1917 the Imperial Government temporarily relieved insular funds of the cost of the local militia. Jersey subsequently contributed £25,000 (December 1917), £50,000 (December 1918) and £25,000 (December 1919), and Guernsey contributed £100,000 (December 1918) to the expenses of the War (1914-18). In 1923 discussions were opened as to further contributions, and in the end Jersey has contributed a further £300,000, and Guernsey £250,000.

Industry.—The Norman system of land tenure, which still survives in the islands, seems to have been superimposed upon a primitive open-field system of cultivation. Traces of the original

system are to be found in Alderney. The soil is extremely fertile. "Vraic" (sea weed) either green, or in the form of ash, has been used as a fertiliser from time immemorial. The cutting of the Vraic became a ceremonial occasion, taking place at times fixed by the government, and connected with popular festivities. Small holdings with intensive cultivation are characteristic of all the Islands. Jersey specialises in early potatoes, Guernsey in bulbs and in flowers and vegetables grown under glass. Other important industries are stock-raising (Jersey and Guernsey have each a special breed of horned cattle and its own herd book), fishing and quarrying. Cattle from abroad are not admitted alive, nor Jersey cattle in Guernsey nor Guernsey cattle in Jersey.

Exports to Great Britain, mainly potatoes, tomatoes, grapes, cut flowers and granite, were valued at £3,445,998 for 1925; imports from Great Britain at £4,324,139 for the same year. The two main sources of income are agriculture and the tourist trade. There is some commerce with France in farm produce and fruit.

Language.—The old Norman French *patois* is dying out. Modern French is the official language, but English is the main language of business and religion and is familiar to all. Each island has its own *patois*; local differences are also observable as between north and south Guernsey. None of the dialects has received much literary cultivation; Jersey was the birthplace of the Norman poet Wace (12th century).

History.—Mousterian man is known to have occupied caves in Jersey, then a part of the mainland. Of early inhabitants abundant proof is afforded by the numerous megalithic monuments, dolmens, kistvaens and maenhirs, still extant. Some of these are of great importance and have been scientifically studied; the local museums are of great value. Little trace has been left of Roman occupation, and such remains as have been discovered are mainly of the portable description that affords little proof of actual settlement. The constant recurrence of the names of saints in the place-names of the islands, and the fact that pre-Christian names do not occur, leads to the inference that when Christianity was introduced the population was scanty. Christianity may have been introduced in the 5th century. Guernsey is said to have been visited in the 6th century by St. Sampson of Dol (whose name is given to a small town and harbour in the island), St. Marcou or Marculfus and St. Magloire, a friend and fellow-evangelist of St. Sampson, who founded monasteries at Sark and at Jersey, and died in Jersey in 575. Another evangelist of this period was St. Helerius, whose name is borne by the chief town of Jersey, St. Helier. In his life it is stated that the population of the island when he reached it was only 30. In 933 the islands were made over to William, duke of Normandy (d. 943). Modern research shows that by 1177 (how long previously is not known) Guernsey and Jersey formed one administrative unit, and were identical with the rest of Normandy. Herm (belonging to the Abbey of Notre Dame du Voeu, Cherbourg) and Jethou (belonging to Mt. St. Michel) may have been under the jurisdiction of Guernsey. Alderney and Sark were separate units, each with its own overlord. After the conquest of England by Normandy it was the policy of the islands to play off one country against the other, meanwhile developing their own independence.

In the reign of John of England the future of the islands was decided by their attachment to the English crown, in spite of the separation of the duchy of Normandy. To John it has been usual to ascribe a document, at one time regarded by the islanders as their Magna Carta; but modern criticism leaves little doubt that it is not genuine. An unauthenticated "copy" of uncertain origin alone has been discovered, and there is little proof of there ever having been an original. The reign of Edward I. was full of disturbance; and in 1279 Jersey and Guernsey received from the king, by letters patent, a public seal as a remedy for the dangers and losses which they had incurred by lack of such a certificate. Edward II. found it necessary to instruct his collectors not to treat the islanders as foreigners: his successor, Edward III., fully confirmed their privileges, immunities and customs in 1347; and his charter was recognized by Richard II. in 1378. In 1343 there was a descent of the French on Guernsey; the governor was defeated, and Castle Cornet besieged. In 1372 there was an

other attack on Guernsey, and in 1374 and 1404 the French descended on Jersey. None of these attempts, however, resulted in permanent occupation. Henry V. confiscated the alien priories which had kept up the same connection with Normandy as before the conquest, and conferred them along with the regalities of the islands on his brother, the duke of Bedford. During the Wars of the Roses, Queen Margaret, the consort of Henry VI., made an agreement with Pierre de Brézé, comte de Maulevrier, the seneschal of Normandy, that, if he afforded assistance to the king, he should hold the islands independently of the crown. A force was accordingly sent to take possession of Mont Orgueil. It was captured and a small part of the island subjugated, and here Maulevrier remained as governor from 1460 to 1465; but the rest held out under Sir Philip de Carteret, seigneur of St. Ouen, and in 1467 the vice-admiral of England, Sir Richard Harliston, recaptured the castle and brought the foreign occupation to an end. In 1482-1483 Pope Sixtus IV., at the instance of King Edward IV., issued a bull of anathema against all who molested the islands; it was formally registered in Brittany in 1484, and in France in 1486; and in this way the islands acquired the right of neutrality, which they retained till 1689. In the same reign (Edward IV.) Sark is said to have been taken by the French, and only recovered in the reign of Mary. By a charter of 1494, the duties of the governors of Jersey were defined. Religious houses were dissolved, as in England, in the reign of Henry VIII. The Reformation was welcomed in the islands, and the English liturgy was translated into French for their use. There was much religious persecution in the reigns of Mary and Elizabeth. In 1568 the islands were transferred from the see of Coutances to that of Winchester, being finally separated from that of Coutances with which they had long been connected.

The Presbyterian form of church government was adopted under the influence of refugees from the persecution of Protestantism on the continent. It was formally sanctioned in St. Helier and St. Peter Port by Queen Elizabeth; and in 1603 King James enacted that the whole of the islands "should quietly enjoy their said liberty." During his reign, however, disputes arose. An episcopal party had been formed in Jersey, and in 1619 David Bandinel was declared dean of the island. A body of canons which he drew up agreeable to the discipline of the Church of England was accepted after considerable modification by the people of his charge; but the inhabitants of Guernsey maintained their Presbyterian practices. Of the hold which this form of Protestantism had got on the minds of the people even in Jersey abundant proof is afforded by the general character of the worship until recently.

In the great struggle between king and parliament, Presbyterian Guernsey supported the parliament; in Jersey, however, there were at first parliamentarian and royalist factions. Sir Philip de Carteret, lieutenant-governor, declared for the king, but Dean Bandinel and Michael Lemprière headed the parliamentary party. They received a commission for the apprehension of Carteret, who established himself in Elizabeth Castle; but after some fighting he died in the castle (1643). Meanwhile in Guernsey Sir Peter Osborne, the governor, was defying the whole island and maintaining himself in Castle Cornet. A parliamentarian governor, Leonard Lydcott, arrived in Jersey immediately after Sir Philip de Carteret's death. But the dowager Lady Carteret was holding Mont Orgueil; George Carteret, Sir Philip's nephew, arrived from St. Malo to support the royalist cause, and Lydcott and Lemprière presently fled to England. George Carteret established himself as lieutenant-governor and bailiff.

Bandinel was imprisoned in Mont Orgueil, and killed himself in trying to escape. Jersey was now completely royalist. In 1646 the prince of Wales, afterwards Charles II., arrived secretly at Jersey, and remained over two months at Elizabeth Castle. He went on to France, but returned in 1649, having been proclaimed king by George Carteret, and at Elizabeth Castle he signed the declaration of his claims to the throne on Oct. 29. In 1651, when Charles had fled to France again after the battle of Worcester, parliamentarian vessels of war appeared at Jersey. On

Dec. 15 the royalist remnant yielded up Elizabeth Castle; and at the same time Castle Cornet, Guernsey, which had been steadily held by Osborne, capitulated. Both islands had suffered severely, and the people of Guernsey, appealing to Cromwell on the ground of their support of his cause, complained that two-thirds of the land was out of cultivation, and that they had lost "their ships, their traffic and their trading." In the reign of James II. the islanders got a grant of wool for the manufacture of stockings—4,000 tods of wool being annually allowed to Jersey, 2,000 to Guernsey, 400 to Alderney and 200 to Sark. Alderney, which had been parliamentarian, was granted after the Restoration to the Carteret family; and it continued to be governed independently till 1825.

William of Orange abolished the neutrality of the islands in 1689, and during the war of 1778-1783 there were two unsuccessful attacks on Jersey, in 1779 and 1781, the second, under Baron de Rullecourt, being famous for the victory over the invaders due to the bravery of the young Major Peirson, who fell when the French were on the point of surrender. During the revolutionary period in France the islands were the home of many refugees. In the 18th century various attempts were made to introduce the English custom house system; but proved practically a failure, and the islands thrived on smuggling and privateering down to the Napoleonic wars, Jersey being also interested in the Newfoundland fisheries as place names in that region testify. The 19th century brought some prosperity from maritime commerce so long as wooden sailing ships were in general use. Later, intensive cultivation for export to English markets has caused unprecedented development.

CHANNEL TUNNEL. A tunnel under the English channel would be one of the engineering wonders of the world, and the longest ever made. The Simplon tunnel through the Alps is 12 miles long; the channel tunnel would be over 30 miles long, of which more than 20 would be under the open sea. The authors of the channel tunnel scheme are confident that it could be made successfully, and their proposals may be thus summarized:—

Construction.—The tunnel would consist of two tubes or tunnels of about 20 ft. diameter, driven about 50 ft. apart and connected by frequent cross galleries. The tunnel would start in France near Wissant, between Boulogne and Calais, and in England behind the Shakespeare cliffs between Dover and Folkestone. The total length would be 31 miles.

The trains would be worked by electricity, and the power station would be situated in Kent at some miles distance from the sea.

The train time in such a tunnel would be about three quarters of an hour and if luggage were examined on trains the 30 or 40 minutes wasted in embarking and disembarking would be saved and the journey to Paris shortened by an hour and a half.

A tube of about 10 ft. diameter would be first driven from shore to shore to serve as a drainage tunnel and to take a light railway. Chambers would be excavated near the middle, and by this means additional facings would be provided for driving the two railway tunnels and the time of construction would thus be greatly shortened.

BY COURTESY OF THE CHANNEL TUNNEL COMPANY

FIG. 1.—ENGLISH HALF, SHOWING SECTION OF TUNNEL FROM BEHIND DOVER CLIFFS TO MID-CHANNEL. THE TUNNEL WOULD INCLUDE TWO TUBES IN THE IMPERMEABLE GREY CHALK, AND DRAINAGE HEADING WITH SHAFT ON THE SHORE, WHERE THE WATER WOULD BE PUMPED UP INTO THE SEA

The estimated time for the whole work is five to six years.

Cost.—The cost is estimated at between 25 and 30 million pounds. It is proposed that one-half the cost be borne by each country. The French companies interested in the scheme believe that it would be financially very profitable—perhaps a second Suez canal—and they have offered, if desired, to find the whole capital,

BY COURTESY OF THE CHANNEL TUNNEL COMPANY

FIG. 2.—CROSS SECTIONS OF THE PROPOSED CHANNEL TUNNEL

but the English companies would not entertain the idea and parliament would not be likely to sanction it.

The tunnel would be bored in the bed of grey chalk which outcrops on the cliffs on both sides, and which, the geologists say, continues right across the straits. Two preliminary tubes, each $1\frac{1}{4}$ miles long, have been driven from Sangatte near Calais and from the shore under Shakespeare cliff, where the old works can

be seen from the railway between Folkestone and Dover. Although these tubes were not lined, the percolation of water into them has been almost nil. The railway tunnels would be lined with steel throughout like the London tubes.

The size of the tunnels would permit the passage of the largest continental express carriages with sleeping and restaurant cars. That English rolling stock can run on the continent was proved during the World War, but the broader and loftier French cars are too big for the English platforms and tunnels and bridges.

The Southern railway, to meet this difficulty, propose to build a new electric railway direct from London to Dover to carry the continental traffic only. It would avoid the towns and be without stations. The present railway lines would be quite unequal to the work of carrying the traffic expected, and the new line should save

BY COURTESY OF THE CHANNEL TUNNEL COMPANY

FIG. 3.—DETAILS OF THE PROPOSED TWIN CHANNEL TUNNEL, SHOWING CONNECTING GALLERY AND DRAINAGE HEADING, ALSO DIFFERENCE IN THE SIZE OF ENGLISH AND CONTINENTAL ROLLING STOCK

another half hour on the journey. Victoria station is too small for the present traffic and cannot well be enlarged. A new continental terminus would therefore have to be built, probably at the junction of Waterloo bridge road and Stamford street.

From this station would run the half hourly service to Paris, the great international expresses to Berlin and Russia, to Brussels, Vienna, and Constantinople, to Rome and Naples, to Madrid and Lisbon, to Biarritz and to the Riviera and Switzerland.

It is a great project, comparable only to the Suez and Panama canals, and one which would do much to ensure the prosperous future of London and England.

History of the Project.—The history of the channel tunnel is sad, dreary, and confused reading. It reflects no credit on any one concerned except the engineers who have perfected the scheme. A French engineer, Thomé de Gamond (1807-75) in 1856 submitted to Napoleon III. the first scheme for a channel

BY COURTESY OF THE CHANNEL TUNNEL COMPANY

FIG. 4.—LONGITUDINAL SECTION OF FRENCH HALF, SHOWING LEVEL OF TUNNEL FROM MID-CHANNEL TO THE MOUTH OF THE TUNNEL IN FRANCE, BEHIND CAP BLANC NEZ, BETWEEN CALAIS AND BOULOGNE, WITH DRAINAGE HEADING AND SHAFT FOR PUMPS ON SEA-SHORE NEAR SANGATTE

tunnel, and he was joined in his work by our great engineers, Isambard Brunel, Joseph Lock, and Robert Stephenson, and later by Sir John Hawkshaw. Queen Victoria and the prince consort were enthusiastic, and the project was seriously taken up by the railway companies on each side of the channel. A convention with the French Government to regulate it was signed in 1875. Then the bitter rivalry of the South Eastern and the Chatham and Dover railway companies created difficulties. The politicians began to play their part. Gladstone, John Bright, Lord Lansdowne, and Lord Salisbury were keen supporters; Joseph Chamberlain and the War Office opposed. The subject was referred to a joint select committee of the Commons, which considered many reports by generals in favour of the proposal and a memorandum by Lord Wolseley, which was a philippic against it. They decided against

nothing could be done. Mr. Lloyd George promised to make more enquiries. Mr. Bonar Law and Mr. Baldwin made no move. Mr. MacDonald in July 1924 offered to consult all the living ex-Prime Ministers. The five met, and, after a 40 minutes meeting, rejected the project, although a majority amongst M.P.s of two to one supported it. Mr. Winston S. Churchill in an article in the *Weekly Dispatch* (July 27, 1924), wrote: "There is no doubt about their promptitude. The question is: Was their decision right or wrong? I do not hesitate to say it was wrong."

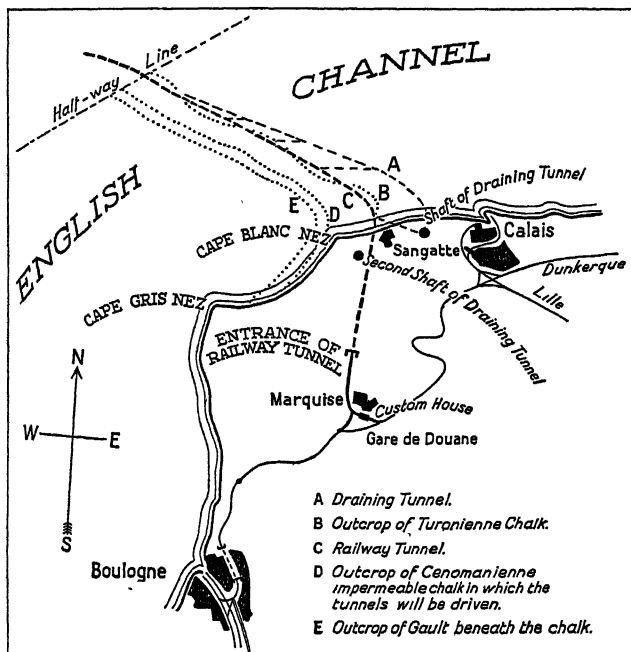

So the channel tunnel scheme was again shelved, but it cannot be killed. It is unquestionably the greatest engineering proposal before the world and in the words of Marshal Foch spoken at a gathering at the Cercle Interallie, Paris, in 1922: "If the channel tunnel had been built it might have prevented the war, and in any event it would have shortened its duration by one half."

The French Channel Tunnel Company has a concession from their Government and can resume work at any moment, but the English Channel Tunnel Company can do nothing without an act of parliament to which no British Government has yet consented.

CHANNING, WILLIAM ELLERY (1780–1842), American divine and philanthropist, was born in Newport (R.I.), April 7, 1780. Channing seemed to have inherited from his father sweetness of temper and warmth of affection, and from his mother that strong moral discernment and straightforward rectitude of purpose and action which formed striking features of his character. He prepared for college in New London under the care of his uncle, the Rev. Henry Channing, to this period tracing the beginning of his spiritual life, and in 1794 entered Harvard college. In his college vacations he taught at Lancaster (Mass.), and in term time he stinted himself in food to save time for study—an experiment which produced acute dyspepsia. Nevertheless, he felt that he got little good from his college course.

After graduating in 1798, he lived at Richmond as tutor in the family of David Meade Randolph, U.S. marshal for Virginia. He returned "a thin and pallid invalid," to spend a year and a half in Newport, which had always delighted him by its beauty, and in 1802 went to Cambridge as regent (or general proctor) in Harvard; in the autumn of 1802 he began to preach. On June 1, 1803, he was ordained pastor of the Federal street Congregational church in Boston. He did not become known as "the apostle of Unitarianism" until after his sermon preached at the ordination of the Rev. Jared Sparks in 1819 and the publication of his articles in *The Christian Disciple*, "Objections to Unitarian Christianity Considered" and "The Moral Argument against Calvinism." He took a keen interest in all public questions; and in 1816 he preached

BY COURTESY OF M. LE TROCQUER

the proposal by 6 to 4, Lord Lansdowne, the chairman, voting with the minority. Since that date the succeeding British Governments have all opposed the scheme.

Blierot landed in his aeroplane at Dover in 1909, and a spontaneous movement in the House of Commons resulted in the formation of a channel tunnel committee which ultimately numbered over 400 members of parliament, under the chairmanship of Sir Arthur Fell. The Labour Party joined *en bloc*, and Mr. Asquith promised to have enquiries made. The World War broke out and

a sermon on war which led to the organization of the Massachusetts peace society. His sermon on "Religion, a Social Principle," helped to procure the omission from the state constitution of the third article of Part I., which made compulsory a tax for the support of religious worship. In Aug. 1821 he undertook a journey abroad, where he met many distinguished men of letters, including Wordsworth and Coleridge; the latter wrote of him, "He has the love of wisdom and the wisdom of love."

As a result of a visit to the West Indies he began to write his book *Slavery* (1835), in which he asserted that "man cannot be justly held and used as property"; that the tendency of slavery is morally, intellectually, and domestically bad; that emancipation, however, should not be forced on slave-holders by governmental interference, but by an enlightened public conscience. He declined to identify himself with the abolitionists, whose motto was "Immediate Emancipation" and whose passionate agitation he thought unsuited to the work they were attempting. In 1837 he published *Thoughts on the Evils of a Spirit of Conquest, and on Slavery: A Letter on the Annexation of Texas to the United States*, addressed to Henry Clay—arguing that the Texan revolt from Mexican rule was largely the work of land-speculators, and of those who resolved "to throw Texas open to slave-holders and slaves"—and warning of its serious consequences. Channing's pamphlet *Emancipation* (1840) dealt with the success of emancipation in the West Indies, as related in Joseph John Gurney's *Familiar Letters to Henry Clay of Kentucky* (1840). In 1842 he published *The Duty of the Free States; or Remarks Suggested by the Case of the Creole*, a careful analysis of the letter of complaint from the American to the British government, and a defence of the position taken by the British government. On Aug. 1, 1842, he delivered at Lenox (Mass.) an address celebrating the anniversary of emancipation in the British West Indies. Two months later, Oct. 2, 1842, he died at Bennington, Vermont.

Physically, Channing was short and slight; his eyes were unnaturally large; his voice wonderfully clear. He was not a great pastor, and lacked social tact, but by the few who knew him well he was almost worshipped. His sermons were noted for their rare simplicity and gracefulness of style. To the name "Unitarian" Channing objected strongly, thinking "unity" as abstract a word as "trinity" and as little expressing the close fatherly relation of God to man. It is to be noted that he strongly objected to the growth of "Unitarian orthodoxy" and its increasing narrowness. Channing believed in historic Christianity and in the story of the resurrection, "a fact which comes to me with a certainty I find in few ancient histories," although he held that the Scriptures were not inspired but merely records of inspiration. In the controversies into which he was forced he continually displayed the greatest breadth and catholicity of view. The differences in New England churches he considered were largely verbal, and he said that "would Trinitarians tell us what they mean, their system would generally be found little else than a mystical form of the Unitarian doctrine." His opposition to Calvinism was so great, however, that even in 1812 he declared "existence a curse" if Calvinism be true. Possibly his boldest and most elaborate defence of Unitarianism was his sermon on *Unitarianism most favourable to Piety*, preached in 1826, and the election sermon of 1830 was his greatest plea for spiritual and intellectual freedom.

Channing's reputation as an author was probably based largely on his publication in *The Christian Examiner* of *Remarks on the Character and Writings of John Milton* (1826), *Remarks on the Life and Character of Napoleon Bonaparte* (1827-28), and an *Essay on the Character and Writings of Fénelon* (1829). An *Essay on Self-Culture* introduced Franklin lectures delivered in Boston in 1838. Channing was an intimate friend of Horace Mann, and his views on the education of children are stated by Elizabeth Palmer Peabody to have anticipated those of Froebel. His *Complete Works* have appeared in various editions since 1841.

See the *Memoir* by W. H. Channing (1848); Elizabeth P. Peabody, *Reminiscences of the Rev. William Ellery Channing, D.D.* (1880), intimate but inexact; J. W. Chadwick, *William Ellery Channing, Minister of Religion* (1903); W. M. Salter, "Channing as a Social Reformer," *Unitarian Review* (March 1888); and C. W. Eliot, *Four American Leaders* (1906).

CHANSONS DE GESTE, the name given to the epic chronicles which take so prominent a place in the literature of France from the 11th to the 15th century. Gaston Paris defined a *chanson de geste* as a song the subject of which is a series of historical facts or *gesta*. These facts form the centre around which are grouped sets of poems, called cycles. It seems probable that as early as the 9th century epic poems began to be chanted by the itinerant minstrels who are known as *jongleurs*. It is conjectured that in a base Latin fragment of the 10th century we possess a translation of a poem on the siege of Girona. Gaston Paris dates from this lost epic the open expression of what he calls "the epic fermentation" of France. But the earliest existing *chanson de geste* is also by far the noblest and most famous, the *Chanson de Roland* (see *ROLAND*). It is in the crowd of looser and later poems, less fully characterized, that we can best study the form of the typical *chanson de geste*. These epics were national and historical; their anonymous writers composed them spontaneously, to a common model, with little regard to the artificial niceties of style. The earlier examples are monotonous, primitive and superficial. Two great merits, however, all the best of these poems possess, force and lucidity; they are full of Gallic pride, they breathe the spirit of an indomitable warlike energy. All their figures belong to the same social order of things, and all illustrate the same fighting aristocracy. The moving principle is that of chivalry, and what is presented is, invariably, the life of a mediaeval soldier.

Perhaps the most important cycle of *chansons de geste* was that which was collected around the name of Charlemagne, and was known as the *Geste du roi*. A group of this cycle dealt with the history of the mother of the emperor, and with Charlemagne himself down to the coming of Roland. To this group belong *Bertha Greatfoot* and *Aspremont*, both of the 12th century, and a variety of *chansons* dealing with the childhood of Charlemagne and of Ogier the Dane. A second group deals with the struggle of Charlemagne with his rebellious vassals. This includes *Girars de Viane* and *Ogier the Dane*, both of the 13th century or late 12th. A third group follows Charlemagne and his peers to the East. It is in the principal of these poems, *The Pilgrimage to Jerusalem*, that Alexandrine verse first makes its appearance in French literature. This must belong to the beginning of the 12th century. A fourth group, antecedent to the Spanish war, is of c. 1200; it includes *Aiquin*, *Fierabras* and *Otinél*. The fifth class discusses the war in Spain, and it is to this that *Roland* belongs; there are minor epics dealing with the events of Roncevaux, and independent *chansons* of *Gui de Bourgogne*, *Gaidon* and *Anseïs de Carthage*. A sixth and last group deals with events up to the death of Charlemagne; this contains *Huon de Bordeaux* and a vast number of poems of minor importance.

Another cycle is that of Duke William Shortnose, *La Geste de Guillaume*. It includes the very early and interesting *Departure of the Aimeri Children*, *Aliscans* and *Rainoart*. This cycle deals with the heroes of the South who remained faithful to the throne. The poems belonging to it are numerous. These *chansons* find their direct opposites in those which form the great cycle of *La Geste de Doon de Mayence*, sometimes called "la faulx geste," because it deals with the feats of the traitors, of the rebellious family of Ganelon. This is the geste of the Northmen, always hostile to the Carolingian dynasty. It comprises some of the most famous of the *chansons*, in particular *Parise la duchesse* and *The Four Sons of Aymon*. Several of its sections are the production of a known poet, Raimbert of Paris. From this triple division of the main body of the *chansons* are excluded certain poems of minor importance.

All the best of the early *chansons de geste* are written in ten-syllable verse, divided into stanzas or *laisses* of different length, united by a single assonance. Rhyme came in with the 13th century, and had the effect in languid bards of weakening the narrative; the sing-song of it led at last to the abandonment of verse in favour of plain historical prose.

See G. Paris, *Histoire poétique de Charlemagne* (1865) and *La Littérature française au moyen âge* (1890); P. Meyer, *Recherches sur l'épopée française* (1867); A. Longnon, *Les Quatre Fils Aïmon*, etc. (1879); L. Gautier, *Les Épopées françaises* (4 vols., 1878-94).

CHANT, the name given to the tunes used in the English Church since the Reformation for the psalms and canticles (Fr. *chant*, from Lat. *cantare*, to sing). For the chant or *cantus firmus* of the Roman Church see PLAIN SONG. In the English chant each section consists of a reciting note of indefinite length, followed by a phrase in regular time called a "mediation." Chants are "single," if written for one verse only, "double," if for two. "Quadruple" chants for four verses have also been written.

CHANTABUN or **CHANTABURI**, the principal town of the Siamese province of the same name, on the east side of the Gulf of Siam, in 102° 6' E., 120° 38' N. It has a small, very mixed population of Annamese, Shans, Burmese and Cambodians and lies about 12m. from the sea on a river which is navigable for boats and has good anchorage for light-draught vessels inside the bar. The trade is chiefly in rubies and sapphires from the mines of the Krat and Pailin districts, pepper, cardamoms and rosewood. In 1905 Chantabun was made the headquarters of a high commissioner, with jurisdiction extending over the coast districts from the Nam Wen on the east to Cape Liant on the west, which were thus united to form a provincial division (Monton). Chantabun has been since the 17th century, and still is, a stronghold of the Roman Catholic missionaries, and the Christian element amongst the population is greater here than anywhere else in Siam.

CHANTADA, a city of north-western Spain, in the province of Lugo. It is situated on the left bank of the Río de Chantada, a small right-hand tributary of the river Miño, and on the main road from Lugo to Orense. Pop. (1920) 13,541. Chantada is the chief town of the fertile region between the Miño and the heights of El Faro. Despite the lack of railway communication, it has a thriving trade in grain, flax, potatoes and dairy produce.

CHANTAGE, a demand for money backed by the threat of scandalous revelations, the French equivalent of "blackmail."

CHANTAL, JANE FRANCES, BARONESS DE (1572-1641), a French saint and the founder of the Order of the Visitation, was born on Jan. 28, 1572, at Dijon, the daughter of the president of the *parlement* of Burgundy. At the age of 20 she married Baron de Chantal, but on his death, four years later, resolved to devote herself to the religious life. In 1604 she met St. Francis de Sales, and her four children now being provided for, she departed for Annecy where she founded the Congregation of the Visitation in June 1610. She was canonized in 1767, her feast being observed on Aug. 21.

See F. M. de Chaugy, *Ste. J. F. de Chantal*, 8 vols. (1874-79); H. Bremond, *Sainte Chantal* (1912); and *The Spirit of St. J. F. de Chantal as shown in her Letters* (1922).

CHANTARELLE, an edible fungus, known botanically as *Cantharellus cibarius* (family, Hymenomycetes) found in woods in summer. It is golden yellow, somewhat inversely conical in shape and about 2in. broad and high. The cap is flattened above with a central depression and a thick lobed irregular margin. Running down into the stem from the cap are a number of shallow thick gills. The substance of the fungus is dry and opaque with a peculiar smell suggesting ripe apricots or plums. The flesh is whitish tinged with yellow. The chantarelle is sold in the markets on the continent of Europe, where it forms a regular article of food, but seems little known in Great Britain; it is common in coniferous woods in the north-eastern United States and Canada. Before being cooked chantarelles should be allowed to dry, and then thrown into boiling water.

CHANTAVOINE, HENRI (1850-1918), French man of letters, was born at Montpellier on Aug. 6, 1850, and died at Galuire (Rhône) on Aug. 15, 1918. He was associated with the *Nouvelle Revue* from its foundation in 1879, and he joined the *Journal des débats* in 1884. His poems include *Poèmes sincères* (1877), *Satires contemporaines* (1881), *Ad memoriam* (1884), *Au fil des jours* (1889).

CHANTILLY, a town of northern France, in the department of Oise, 25 m. N. of Paris on the Northern railway to St. Quentin. Pop. (1926) 5,073. It is situated to the north of the forest of Chantilly and is one of the favourite Parisian resorts. Its name was long associated with the manufacture, now decayed, of lace and blonde; it is still more celebrated for its château and its park

(laid out originally in the 17th century), and as the scene of the annual races of the French Jockey Club. The château consists of the palace built from 1876 to 1885 and of an older portion adjoining it known as the châtelet. In the reign of Charles VI. the lordship belonged to Pierre d'Orgemont, chancellor of France. In 1484 it passed to the house of Montmorency, and in 1632 to the house of Condé. Louis II., prince de Condé, enjoyed here the society of La Bruyère, Racine, Molière, La Fontaine, Boileau and others. The stables close to the racecourse were built from 1719 to 1735 by the duke of Bourbon. The grand château was destroyed about the time of the Revolution, but the châtelet still remains one of the finest specimens of Renaissance architecture in France. The château d'Enghien, facing the entrance to the grand château, was built in 1770 as a guest-house. In 1830 the estate passed into the hands of Henri, duc d'Aumale, fourth son of Louis Philippe. In 1852 the house of Orléans was declared incapable of possessing property in France, and Chantilly was accordingly sold by auction, but passed back into the hands of the duc d'Aumale who built the palace, on the foundations of the grand château. He installed in the châtelet a valuable library and a collection of paintings. In 1886 he gave the park and château with its collections to the Institute of France in trust for the nation, reserving to himself only a life interest.

CHANTREY, SIR FRANCIS LEGATT (1781-1841), English sculptor, was born on April 7, 1781, at Norton, near Sheffield. After receiving lessons in carving and painting, Chantrey went to try his fortune in Dublin and Edinburgh, and finally (1802) in London. He exhibited pictures at the Academy for some years from 1804, but from 1807 onwards devoted himself mainly to sculpture. His first imaginative work in sculpture was the model of the head of Satan, which was exhibited at the Royal Academy in 1808. He afterwards executed for Greenwich hospital four colossal busts of the admirals Duncan, Howe, Vincent and Nelson; and the next bust which he executed, that of Horne Tooke, procured him commissions to the extent of £12,000. He received many honours, was elected R.A. in 1818, and received a knighthood in 1835. He died suddenly on Nov. 25, 1841.

His principal works are the statues of Washington in the State House at Boston, U.S.A.; of George III. in the Guildhall, London; of George IV. at Brighton; of Pitt in Hanover Square, London; of James Watt in Westminster Abbey; of Canning in Liverpool; of Lord President Blair and Lord Melville in Edinburgh. Of his equestrian statues the most famous are those of Sir Thomas Munro in Calcutta and the duke of Wellington in front of the London Exchange. But the finest of Chantrey's works are his busts and his delineations of children. The figures of two children asleep in each other's arms, which form a monumental design in Lichfield cathedral, have always been admired for beauty, simplicity and grace. Allan Cunningham and Weekes were his chief assistants, and were indeed the active executants of many works that pass under Chantrey's name. See A. J. Raymond, *Life and work of Sir Francis Chantrey* (1904); for his will see CHANTREY BEQUEST.

CHANTREY BEQUEST. By the will dated Dec. 31, 1840, Sir Francis Chantrey (*q.v.*), left his whole residuary personal estate after the decease or on the second marriage of his widow (less certain specified annuities and bequests) in trust for the president and trustees of the Royal Academy (or in the event of the dissolution of the Royal Academy, to such society as might take its place), the income to be devoted to the encouragement of British fine art in painting and sculpture only, by "the purchase of works of fine art of the highest merit . . . that can be obtained." The funds might be allowed to accumulate for not more than five years; works by British or foreign artists might be acquired, so long as such works were entirely executed in Great Britain. The prices were to be "liberal," and no sympathy for an artist or his family was to influence the selection or the purchase of works, which were to be acquired solely on the ground of intrinsic merit. No commission or orders might be given: the works must be finished before purchase. An annual sum of £300 and £50 was to be paid to the president of the Royal Academy and the secretary respectively, for the discharge of their duties in

carrying out the provisions of the will.

Lady Chantrey died in 1875, and two years later the fund became available for the purchase of paintings and sculptures. The capital sum amounted to £105,000. Galleries in the Victoria and Albert Museum at South Kensington were at first used, until in 1898 the Royal Academy arranged with the Treasury for the transference of the collection to the National Gallery of British Art, which had been erected by Sir Henry Tate at Millbank.

A growing discontent with the interpretation by the Royal Academy of the terms of the will found forcible expression in the press in 1903, and a debate in the House of Lords led to the appointment of a select committee of that House (June to Aug. 1904). Its report made recommendations with a view to the prevention of certain former errors of administration, but dismissed other charges against the Academy. A memorandum was issued by the Royal Academy (Feb. 1905) disagreeing with certain recommendations, but allowing others.

See *The Administration of the Chantrey Bequest*, by D. S. MacColl (1904), a highly controversial publication; *Chantrey and His Bequest*, by Arthur Fish, a complete illustrated record of the purchases, etc. (1904); *The Royal Academy, its Uses and Abuses*, by H. J. Laidlay (1898), controversial; *Report from the Select Committee of the House of Lords on the Chantrey Trust; together with the Proceedings of the Committee, Minutes of Evidence and Appendix* (1904).

CHANT ROYAL, one of the fixed forms of verse invented by the ingenuity of the poets of mediaeval France. It is composed of five verses, identical in arrangement, of 11 lines each, and of an envoi of five lines. All the verses are written on the five rhymes exhibited in the first verse, the entire poem, therefore, consisting of 60 lines in the course of which five rhymes are repeated. It has been conjectured that the chant royal is an extended ballade, or rather a ballade conceived upon a larger scale; but which form preceded the other appears to be uncertain. On this point Henri de Croÿ, who wrote about these forms of verse in his *Art et science de rhétorique* (1493), throws no light. He dwells, however, on the great dignity of what he calls the "Champt Royal," and says that those who defy with success the ardour of its rules deserve crowns and garlands for their pains. Étienne Pasquier (1529-1615) points out the fact that the chant royal, by its length and the rigidity of its structure, is better fitted than the ballade for solemn and pompous themes. In old French, the most admired chants royaux are those of Clement Marot; his *Chant royal chrestien*, with its refrain
Santé au corps, et Paradis à l'âme,

was celebrated. Théodore de Banville defines the chant royal as essentially belonging to ages of faith, when its subjects could be either the exploits of a hero of royal race or the processional splendours of religion. La Fontaine was the latest of the French poets to attempt the chant royal, until it was resuscitated in modern times.

This species of poem was unknown in English mediaeval literature and was only introduced into Great Britain in the last quarter of the 19th century. The earliest chant royal in English was that published by Edmund Gosse in 1877, "The Praise of Dionysus."

In the middle ages the chant royal was largely used for the praise of the Virgin Mary. Eustache Deschamps (1340-1410) distinguishes these Marian chants royaux, which were called "serventois," by the absence of an envoi. These poems are first mentioned by Rutebeuf, a *trouvère* of the 13th century. The chant royal is practically unknown outside French and English literature.

CHANTRY, a small chapel in or adjoining a church, endowed for maintaining priests to chant masses for the soul of the founder or of some one named by him. It generally contained the founder's tomb and had an entrance from the outside for the chantry priest. The word is applied either to the endowment funds or to the chapel itself.

CHANUTE, a city of Neosho county, Kansas, U.S.A., 120m. S. S.W. of Kansas City, near the Neosho river. It is on Federal highway 73W, and is served by the Missouri-Kansas-Texas and the Santa Fe railways. The population in 1925 (State census) was 9,829; in 1930, 10,277. Chanute is in the mid-continent

oil and gas field, and is surrounded by a fine farming and fruit-growing country. Shale and clay are found near by. Shale-gas provides a cheap industrial fuel. The city is headquarters of a division of the Santa Fe system. It has smelters, refineries, railroad shops, flour-mills, vitrified brick, tile, cement and glass works. The factory output in 1927 was valued at \$3,208,520.

Four towns—New Chicago, Tioga, Chicago Junction and Alliance—founded here about 1870, were consolidated in 1872, and named after Octave Chanute (b. 1832), civil engineer and aeronautist, who was the engineer of the railway then under construction. Natural gas and oil were discovered in 1899.

CHANZY, ANTOINE EUGÈNE ALFRED (1823-1883), French general, was born at Nouart (Ardennes) on March 18, 1823. The son of a cavalry officer, he was educated at the naval school at Brest, but enlisted in the artillery, and was commissioned in the Zouaves in 1843. Although he acquired an excellent professional reputation during war service in Algeria and in Lombardy, he was in bad odour at the War Office on account of suspected contributions to the press, and at the outbreak of the Franco-German War was refused a brigade command. After the revolution, however, the government of national defence gave him command of the XVI. Corps of the army of the Loire. (For the operations of the Orleans campaign which followed, see FRANCO-GERMAN WAR.) After the second battle of Orleans and the separation of the two wings of the French army, Chanzy was appointed to command that in the west, designated the second army of the Loire. He displayed conspicuous moral courage in the fighting from Beaugency to the Loire, in his retreat to Le Mans, and in retiring to Laval behind the Mayenne. He was made a grand officer of the Legion of Honour, and was elected to the National Assembly. At the beginning of the commune, Chanzy, then at Paris, fell into the hands of the insurgents, by whom he was liberated on giving his parole not to serve against them. A ransom of £40,000 was also paid by the Government for him. In 1872 he became a member of the committee of defence and commander of the VII. Army Corps, and in 1873 was appointed governor of Algeria, where he remained for six years. In 1875 he was elected a life senator, in 1878 received the grand cross of the Legion of Honour, and in 1879, without his consent, was nominated for the presidency of the republic, receiving a third of the total votes. For two years he was ambassador at St. Petersburg (Leningrad). He died suddenly, while commanding the VI. Army Corps at Châlons-sur-Marne, on Jan. 4, 1883, and his remains received a state funeral. He was the author of *La Deuxième Armée de la Loire* (1872).

parody (*Birds*, 691) the winged Eros in conjunction with gloomy Chaos brings forth the race of birds. The later Roman conception (Ovid, *Metam.* i. 7) makes Chaos the original crude, shapeless

mass, into which the architect of the world introduces order and harmony, and from which individual forms are created. When contrasted with cosmos (the orderly universe) the word has various meanings:—the space between heaven and earth; the underworld and its ruler; the immeasurable darkness; the indefinite in space and time. In modern usage "chaos" denotes a state of disorder and confusion.

CHAPACURAN, a tribe or small group of tribes of South American Indians, regarded on rather slender evidence as constituting an independent linguistic stock. The stock, which comprises the Ites, Pawumwas and other smaller tribes in addition to the Chapacuras, seems to have occupied the whole of the basin of the Rio Blanco in north-eastern Bolivia, together with the Guaporé from the mouth of the Blanco to its confluence with the Mamore, as well as the eastern tributaries of the Guaporé between 12° and 13° S. Lat. The Chapacuras themselves lived on the Rio Blanco and about lake Chitiopa. They were a peaceful, sedentary agricultural folk, whose culture was generally similar to that of the Chiquitos (*q.v.*). The Pawumwas go almost naked, and use the blow-gun with poisoned darts.

See G. de Crequi-Montfort and P. Rivet, *Linguistique Bolivienne; La famille linguistique Capakura* (*J. Soc. Américanistes de Paris* [n.s.], vol. x., pp. 119-173); J. D. Haseman, *Some notes on the Pawumwa Indians* (*American Anthropologist* [n.s.], vol. xiv., pp. 333-350).

CHAPAIS, JOSEPH AMABLE THOMAS (1858–), Canadian lawyer, statesman and historian, was born at St. Denis-de-la-Bouteillerie, Quebec, on March 23, 1858, son of Senator J. C. Chapais, one of the "Fathers of Confederation." Joseph Chapais was educated at St. Anne's college, Laval university, and was called to the Quebec bar in 1879. In March 1892 he was called to the legislative council of Quebec, was a minister without portfolio in the Taillon Government, and was elected leader of the Government in the executive council (Jan. 1893); speaker of the legislative council (April 1895); president of the executive council (May 1896), and minister of colonization and mines (Jan. 1897). He retired from office in May, 1897. From 1884 to 1901 Chapais edited *Le Courrier du Canada* of Quebec. In 1907 he was appointed professor at Laval university, and has published several works on history and law, including *Cours d'Histoire du Canada, 1760-1814* (4 vols., 1916-23); *Jean Talon* (1904); and *Le Marquis de Montcalm* (1911). On Dec. 31, 1919, he was called to the senate of Canada.

CHAPARRAL, a mixed forest formation of low hard-leaved, stunted trees and shrubs resulting from short, wet, cool winters and long, arid, hot summers. The word is believed to have been derived from *chaparro*, the Spanish name for live oak. Chaparral grows slowly and shrubs 25 years old will usually average not more than 2 or 3 in. in diameter and 5 or 6 ft. in height. This type of forest growth occurs chiefly in southern California in the United States, along the coast of Chile, in Europe and Asia along the Mediterranean and as far east as Turkistan, in Africa near the Cape of Good Hope and on the southern and southwestern coasts of Australia and Tasmania. Its chief economic value lies in its ability to conserve water supply, which it accomplishes below the surface through its root system and above the surface by breaking the force of hot winds and shading the ground to prevent evaporation.

Of the 150 different species of woody plants believed to exist in the chaparral of Southern California 20 dominant types—among them chamise, manzanita, ceanothus, sumac, sage, scrub oak and buckthorn (*qq.v.*)—represent 90% of the growth. In former times the Indians used the nuts, berries and seeds of several of the varieties for food. Some species were once in demand as fuel supply and others are still used for fencing. The bee industry flourishes in the chaparral region, several profusely flowering shrubs, as the black sage, being excellent honey plants. It is estimated that there are 5,500,000 acres of chaparral in the United States. Chaparral formations protect the upper watersheds of the coastal streams in California for a distance of about 450 miles.

CHAPBOOK, the comparatively modern name applied by booksellers and bibliophiles to the little stitched tracts written

for the common people and formerly circulated in England, Scotland and the American colonies by itinerant dealers or chapmen, consisting chiefly of vulgarized versions of popular stories, such as *Tom Thumb*, *Jack the Giant Killer*, *Mother Shipton*, and *Reynard the Fox*—travels, biographies and religious treatises. Few of the older chapbooks exist. Samuel Pepys collected some of the best and had them bound into small quarto volumes which he called *Vulgaria*; also four volumes of a smaller size, which he lettered *Penny Witticisms*, *Penny Merriments*, *Penny Compliments* and *Penny Godlinesses*. The early chapbooks were the direct descendants of the black letter tracts of Wynkyn de Worde. It was in France that the printing-press first began to supply reading for the common people. At the end of the 15th century there was a large popular literature of farces, tales in verse and prose, satires, almanacs, etc., stitched together so as to contain a few leaves, and circulated by itinerant booksellers, known as colporteurs. Most early English chapbooks are adaptations or translations of these French originals, and were introduced into England early in the 16th century. The chapbooks of the 17th century present us with valuable illustrations of the manners of the time; one of the best known is that containing the story of Dick Whittington. In France literature of this kind has been the object of close and systematic study, and *L'Histoire des livres populaires ou de la littérature du colportage* by Charles Nisard (1854) goes deeply into the subject. Amongst English books may be mentioned *Notices of Fugitive Tracts and Chapbooks*, by J. O. Halliwell-Phillipps (1849); *Chapbooks of the 18th Century*, by John Ashton (1882), and some reprints by the Villon Society in 1885.

CHAPE, a cover or metal plate, such as the cap upon the needle in the compass, also the transverse guard of a sword which protects the hand (Fr. *chape*, a hood, cope or sheath); also, a support or catch to attach one thing to another, as the hook on a belt to which the sword is fastened; and the tip of a fox's brush.

CHAPEL, a place of religious worship, either a subordinate division of a church, or a separate building distinguished from a church by the special conditions of its foundation or use. *Capella*, the diminutive of *cappa*, a cloak, was the name given to the shrine in which the cloak (*cappa brevior*) of St. Martin was kept and carried about by the Frankish kings on their journeys, when oaths were taken on it. This peculiar use was transferred to any sanctuary containing relics, the priest of which was called *capellanus* or chaplain. By a further extension, the word was identified with all places of worship which were not mother churches (*ecclesiae matricēs*), so as to include a large number of miscellaneous foundations. Most nearly akin to the original meaning is the application of the term to the oratories attached to royal residences. Thus the Sainte Chapelle, the palace chapel at Paris, consecrated in 1248, was built by St. Louis to enshrine the relic of the Crown of Thorns, ransomed by him from the Venetians, who held it in pawn from John of Brienne, the Latin emperor of the East. In the next century, chapels were founded by princes of the French royal house at Bourges, Riom and elsewhere for which the same title was adopted. Such chapels royal were usually founded as collegiate establishments, like Edward III.'s chapels of St. Stephen at Westminster and St. George at Windsor. Collegiate chapels were also founded by prelates and noblemen in connection with their castles and manor-houses, such as the chapel of St. Mary and the Holy Angels at the gate of the palace at York, founded by Archbishop Roger (1154-81), and that of St. Elizabeth before the gate of Wolvesey Castle at Winchester, founded by Bishop John of Pontoise (1282-1304).

The chapel of the castle or manor-house, however, was generally served by a single domestic chaplain. For oratories in connection with private houses an episcopal licence was required, so as to safeguard the rights of the churches in whose parishes they were established. Though frequently within the house itself, they were also erected as separate buildings, and some, which served as churches for the lord of the manor and his tenants, acquired the status of free chapels, which implied exemption from parochial and archidiaconal, and occasionally, though not always, from episcopal jurisdiction. Certain churches, in the patronage of the Crown or

owing their foundation to the king, were regarded as royal free chapels and free chapels on manors probably originated in the grant of special privileges to their owners by the Crown. In time, such free chapels, governed by rectors, sometimes lost their peculiar character and were reckoned as parish churches; but, where the status of a free chapel remained, their incumbents were held to be without cure of souls.

Parish Chapels.—More numerous, however, than free chapels were the chapels in outlying hamlets of large parishes, maintained by the inhabitants and served daily, or on certain days in the week, by chaplains provided at the expense of the parochial incumbent. Some of these, which, as time went on, acquired rights of baptism and burial, were parochial chapels; others, merely chantry chapels in small villages, without such rights, were, properly speaking, chapels of ease. The origin of such foundations was usually the difficulty experienced by the inhabitants in attending the mother church in bad weather, when the streams were swollen and the roads impassable. In Leicestershire, early in the thirteenth century, there were more than a hundred of these dependent chapels in about two hundred parishes, and the proportion elsewhere was not very different.

Subordinate Buildings.—The idea of a chapel as a subordinate or dependent building is implied by its use for the areas appropriated to the minor altars within or projecting from the walls of a church. The services held in these were called chantries (*cantuarie*), and, by a transference of ideas to which there are many parallels in mediaeval usage, the chapels themselves were often known as chantries. Of the use of chapel to signify the oratory of a private establishment, the most familiar examples are the chapels of colleges at Oxford and Cambridge. Similarly the places of worship in hospitals, almshouses, etc., are called chapels, as well as those which, like chapels of cemeteries, are generally restricted to some special use. Proprietary chapels, founded in London and other English towns during the eighteenth and early nineteenth centuries, were established, with a licence for divine service, by private individuals or groups of trustees. The growth of Nonconformity, however, gave the word a particular application to dissenting places of worship. In Ireland the term has clung persistently to those of the Roman Church, a survival of an old use which in England was derived from the chapels or religious establishments maintained by Henrietta Maria and other Roman Catholic queens. But, apart from this, the modern tendency is to abandon the employment of the word for special classes of religious building, and to give the title church to all indiscriminately.

There are many instances in mediaeval wills and inventories of the application of the term chapel to sets of vestments and altar furniture, as constituting the necessary fittings of a private oratory. Another transference of the sense occasionally found is from the chapel itself to the collective members of the foundation.

(A. H. T.)

CHAPEL. In the printing trade, the name of the fellowship of compositors (and, nowadays, of all crafts) in a printing works. The president is termed the "father of the chapel." In the United States he is called "the chairman." The name chapel is used not only of the fellowship itself but of the meetings which it holds. At these meetings, the chapel discusses such things as the general welfare of the body, the conditions of work, relations with employers, and trade union matters.

The accepted version of the origin of the use of the word chapel in this connection is that it is derived from the fact that Caxton first set up his press in or near Westminster Abbey. Writing in 1716, Myles Davies, in his *Athenae Britannicae* says, "William Caxton first practis'd Printing in the Abbey of Westminster, A.D. 1471, thence a Printing-Room came to be call'd a Chappell amongst our Printers." Another explanation is offered by Joseph Moxon, who in his *Mechanick Exercises* (1683) says, "Every Printing-house is by the Custom of Time out of mind, called a Chappel: and all the Workmen that belong to it are Members of the Chappel: and the oldest Freeman is Father of the Chappel. I suppose this stile was originally conferred upon it by the courtesie of some great Churchman, or men (doubtless when Chappels were in more veneration than of late years they have been here

in England), who for the Books of Divinity that proceeded from a Printing-house gave it the Reverend Title of Chappel."

CHAPELAIN, JEAN (1595-1674), French poet and man of letters, was born in Paris and spent 17 years in the service of M. de la Trousse, grand provost of France. He was employed by Richelieu in the organization of the Académie Française. In 1632, in a conversation with the cardinal, he had laid down the canon of the unities of time and space which should govern the drama. The unities had already been advocated by Scaliger (*Art poétique*, 1561) and by the abbé d'Aubignac (*Pratique du théâtre*, 1657), but the doctrine appears to have been unfamiliar to Richelieu, who invited Chapelain to draw up the *Sentiments de l'Académie sur le Cid*, in which deviation from the rule is denounced. His great reputation seemed to be enhanced by the success of the first 12 cantos of his epic *La Pucelle* (1656), on which he had been at work for 20 years, but it was shattered by Boileau in his early satires, and the remaining cantos of the epic remained unprinted until 1882, when they were edited by H. Herluison.

Chapelain drew up the statutes of the Academy, and laid down the rules for the great grammar and dictionary to be produced. In 1663 he was employed by Colbert to draw up a list of men of letters with observations for use by the Crown in the distribution of honours and pensions. This task showed him to be a generous and kindly critic.

BIBLIOGRAPHY.—There is a very favourable estimate of Chapelain's merits as a critic in George Saintsbury's *History of Criticism*, ii. 256-261. An analysis of *La Pucelle* is given in pp. 23-79 of Robert Southey's *Joan of Arc*. See also *Les Lettres de Jean Chapelain* (edit. P. Tanuzey de Larroque, 1880-82); *Lettres inédites . . . à P. D. Huët* (1658-73, edit. L. G. Pellissier, 1894); Julien Duchesne, *Les Poèmes épiques du XVII^e siècle* (1870); the abbé A. Fabre, *Les Ennemis de Chapelain* (1888), *Chapelain et nos deux premières Académies* (1890); A. Muehlan, *Jean Chapelain* (1893).

CHAPEL-EN-LE-FRITH, a market town in Derbyshire, England, 5m. N. of Buxton, on the L.M.S.R. Pop. (1921) 5,283. It lies in an upland valley of the Peak district. The foundation of the church of St. Thomas of Canterbury is attributed to foresters of the royal forest or *frith* of the Peak early in 13th century; from this the town took name. Pop. rural dist. (1931) 17,758.

CHAPEL HILL, a town of Orange county, North Carolina, U.S.A., on a high ridge 28m. N.W. of Raleigh, in a tobacco and cotton-growing district. It is on Federal highway 15, and is served by the Southern railway. The population in 1930 was 2,699. It is the seat of the University of North Carolina (*q.v.*), which occupies a beautiful campus of 106ac. and owns an adjoining tract of 500ac. in forest lands. The town has a council-manager form of government.

CHAPELLE ARDENTE, the chapel or room in which the corpse of a sovereign or other exalted personage lies in state pending the funeral service. The name is in allusion to the many candles which are lighted round the catafalque. This custom is first chronicled as occurring at the obsequies of Dagobert I. (602-638).

CHAPERON, originally a cap or hood (Fr. *chape*) worn by nobles and Knights of the Garter in full dress, and after the 16th century by middle-aged ladies. In the 19th century the word was used of a married or elderly lady (*cf.* "duenna") escorting or protecting a young and unmarried girl in public places and in society.

CHAPLAIN, originally, according to Du Cange (*Gloss. med. et inf. Lat.*), the custodian of the cloak (*capa* or *capella*) of St. Martin of Tours, which was preserved as a relic by the French kings, and carried with the army in war-time, when it was kept in a tent known itself as *capella* (Fr. *chapelain*; M. Lat. *capellanus*). It is also suggested that the *capella* was the tent-like canopy erected by the French kings over the altar for soldiers in the field, without special reference to St. Martin. However this may be, the name *capellanus* was generally applied to custodians of sacred relics preserved in royal chapels, etc.; and the office gradually extended its scope, *capellani* acquiring spiritual jurisdiction and increasing in number, so that an arch-chaplain was appointed as their head, who from the time of Charlemagne was a high prelate,

and who became an important personage in the realm. In France the arch-chaplain was grand-almoner, and both in France and in the Holy Roman Empire was also high chancellor of the realm. The office was abolished in France in 1789, revived by Pius IX. in 1857, and again abolished on the fall of the Second Empire. The word chaplain now signifies a clergyman attached to the household of a sovereign or his representatives (ambassadors, judges, etc.), or of a bishop or nobleman, or private individual having a chapel in his house, to the army or navy, or to institutions (e.g. parliament, colleges, cemeteries, prisons). As chaplain he has no parochial duties, but in some cases a parish priest is also appointed to a chaplaincy; e.g. an Anglican bishop often appoints beneficed clergymen as his examining chaplains. The British sovereign has 36 "Chaplains in Ordinary," who officiate in rotation, as well as "Honorary Chaplains" and "Domestic Chaplains." There are also royal chaplains in Scotland. The Indian civil service appoints a number of chaplains of the Church of England and the Church of Scotland, who are subject to the same conditions as other civil servants. Chaplains are also appointed under the Foreign Office to embassies, consulates, etc. Workhouse chaplains are appointed by overseers and guardians on the direction of the Ministry of Health. Prison chaplains are appointed by the home secretary.

In the British army there are two kinds of chaplains, permanent and occasional. The former, described as Chaplains to the Forces, hold commissions, serving throughout the empire except in India; they number about 100, and include a Chaplain-General who ranks as a major-general, and four classes of subordinate chaplains who rank respectively as colonels, lieutenant-colonels, majors and captains. Special chaplains (Acting Chaplains for Temporary Service) may be appointed by a secretary of state. Permanent chaplains may be Church of England, Roman Catholic or Presbyterian; Wesleyans (if they prefer not to accept commissions) may be appointed Acting Chaplains. In the navy, every large ship in commission has a chaplain; at the head of the naval chaplains is the Chaplain of the Fleet. But the ecclesiastical superior of all Roman Catholic chaplains in both army and navy is the archbishop of Westminster, by decree of Propaganda (1906). In 1909 a Chaplains' Department of the Territorial Force was formed, having no denominational restriction.

In France, military and naval chaplaincies were abolished on the separation of Church and State. In the army of the United States of America the establishment of chaplains was fixed in 1904 by Congress at 57 (15 with the rank of major), 12 for the artillery corps and one each for the cavalry and infantry regiments. There is no distinction of sect. In the U.S. navy the chaplains number 24, 13 ranking as lieutenants, seven as commanders, four as captains.

The Roman Catholic Church also recognizes a class of beneficed chaplains, supported out of "pious foundations" for the specific duty of saying, or arranging for, certain masses, or taking part in certain services. These chaplains are classified as follows:—*Ecclesiastical*, if the foundation has been recognized officially as a benefice; *Lay*, if this recognition has not been obtained; *Mercenary*, if the benefaction has been entrusted to a layman to procure the desired celebration (such trustees are sometimes called "Lay Chaplains"); *Collative*, if it is provided that a bishop shall erect the foundation into a benefice.

Other classes of chaplains are:—(1) *Parochial* or *Auxiliary Chaplains*, appointed to assist a parish priest (usually by the bishop, but sometimes by the parish priest, as allowed by the Council of Trent); (2) *Chaplains of Convents*, appointed by a bishop: these must be men of mature age, should not be regulars if secular priests can be obtained, and are not generally appointed for life; (3) *Pontifical Chaplains*, some of whom (known as Private Chaplains) assist the pontiff in the celebration of Mass; others attached directly to the pope are honorary private chaplains who occasionally assist the private chaplains, private clerics of the chapel, common chaplains and supernumerary chaplains. The common chaplains were instituted by Alexander VII., and in 1907 were definitely allowed the title "Monsignore"—pertaining also to cardinals, archbishops, and bishops—by Pius X.

CHAPLIN, CHARLES SPENCER (1889–), cinema actor, was born April 16, 1889, of English parentage, and passed his childhood in London. At an early age he appeared on the music-hall stage with his father and his brother Sydney, taking small parts in vaudeville. After a short experience on the legitimate stage, he re-entered vaudeville in London as a member of the Fred Karno company. In 1910 he went to the United States as leading comedian in a Karno production, *A Night in an English Music Hall*. He attracted the attention of Joseph M. Schenck, and on the latter's suggestion he was engaged by Mack Sennett to make films with the Keystone Comedy Company at Hollywood, California. In his first picture, made in 1913, he adopted the eccentric costume which has ever since been associated with his name. His success was immediate, continuous and universal. In 1918 he formed his own company, and he produced a series of films which placed him in the front rank of artists and in a category of his own in the field of screen comedy. Among the more successful of his later releases were: *A Dog's Life* (1918), *Shoulder Arms* (1918), *The Kid* (1921), *The Idle Class* (1921), *The Gold Rush* (1925), and *The Circus* (1926). In all of these he was the central figure. In 1923 he directed, but did not personally appear in, *A Woman of Paris*, a serious picture, displaying great skill in construction and ensemble.

CHAPLIN, HENRY CHAPLIN, 1ST VISCOUNT (1840–1923), English statesman, son of the Rev. Henry Chaplin, of Blankney, Lincolnshire, was born Dec. 22, 1840, and died May 29, 1923. He was educated at Harrow and Christ Church, Oxford. Entering parliament in 1868, he sat as Conservative member, first for Mid-Lincolnshire (1868–1906), and then for Wimbledon. As the typical English country gentleman, the "Squire of Blankney" was one of the leaders of the agricultural interest. He was chancellor of the duchy of Lancaster (1885–86) and president of the new Board of Agriculture (1889–92); as president of the Local Government Board (1895–1900) he was responsible for the Agricultural Rates Act of 1896, and he was a member of Mr. Chamberlain's Tariff Commission. During the Coalition government of 1915, Chaplin was the leader of the nominal opposition until his elevation to the peerage in 1916.

See E. Stewart, *Henry Chaplin* (1926).

CHAPMAN, FRANK M. (1864–), American ornithologist, was born at Englewood, N.J. on June 12, 1864. From 1887–1908 he served as associate curator of ornithology and mammalogy, and from then until the present time as curator of ornithology, American Museum of Natural History. In 1897 he was elected president of the Linnaean Society of New York, and, in 1911, of the American Ornithologists' Union. He was originator of the habitat bird groups and seasonal bird exhibits at the American Museum of Natural History, and was a pioneer in bird study with a camera in America. He acted as director of the Bureau of Publications of the American Red Cross (1917–18) and commissioner of the American Red Cross to Latin America (1918–19). He was associate editor of *The Auk* (1894–1911) and is editor-in-chief of *Bird-Lore*, which he founded in 1899. Since 1911 he has devoted much time to a study of the origin of Andean bird-life and has explored in the Andes.

His publications are: *Handbook of Birds of Eastern North America* (1895); *Bird-Life, a Guide to the Study of our Common Birds* (1897); *Bird Studies with a Camera* (1900); *A Color Key to North American Birds* (1903); *The Economic Value of Birds to the State* (1903); *The Warblers of North America* (1907); *Camps and Cruises of an Ornithologist* (1908); *The Travels of Birds* (1916); *The Distribution of Bird-Life in Colombia* (1917); *Our Winter Birds* (1918); *What Bird is That?* (1920); *Birds of the Urubamba Valley, Peru* (1921); *The Distribution of Bird-Life in Ecuador* (1926); *My Tropical Air Castle* (1929); also numerous papers on birds and mammals.

CHAPMAN, GEORGE (1559–1634), English poet and dramatist, translator of Homer, was born near Hitchin. There is no record of his university career, though Anthony Wood (*Athen. Oxon.* ii. 575) claims that he spent some time in Oxford. He had become a play-writer in London, and had published some poems when he appeared in Henslowe's *Diary* on Feb. 12, 1596, as the author of the *Blind Beggar of Alexandria*. Thenceforward his name repeatedly appears in connection with payments for various plays until 1599, after which date he appears to have

written masques for the Children of the Chapel (afterwards of the Revels) in the intervals of working on the translation of Homer. In 1598 he had completed Marlowe's poem, *Hero and Leander*. Apparently he was imprisoned for a short time for his share in the play *Eastward Hoe*, which gave offence to James I. by certain quips against the Scots. He was encouraged in his translation of Homer by Prince Henry, to whom he was server in ordinary, but on the prince's death in 1612 Chapman lost his appointment and the promise of a life pension made by the prince was not fulfilled. He found a new patron in Robert Carr, earl of Somerset, to whom the two folio volumes *The Whole Works of Homer, Prince of Poets, in his Iliads and Odyssees* (1616) are dedicated. *The Crowne of all Homer's Workes, Batrachomyomachia, or the Battaille of Frogs and Mice. His Hymns and Epigrams* appeared in 1624. The poet died on May 12, 1634.

Chapman enjoyed the friendship and admiration of his great contemporaries. John Webster in the preface to his *White Devil* praised his "full and heightened style," and Ben Jonson told Drummond of Hawthornden that Fletcher and Chapman "were loved of him." But the good relations with Jonson were apparently interrupted later. It was suggested by William Minto, who has been followed by later writers, that Chapman was the "rival poet" of Shakespeare's sonnets. Sir E. K. Chambers, however, thinks that the assumption would be more plausible if any relation between the earl of Southampton and Chapman, earlier than a stray dedication shared with others in 1609, could be established.

Chapman's *Homer* gives him a high place in English literature. Swinburne, in the criticism contributed to an earlier edition of the *Encyclopædia Britannica*, gave an admirable and considered judgment of the work. "The objections," he said, "which a just and adequate judgment may bring against Chapman's master-work, his translation of Homer, may be summed up in three epithets: it is romantic, laborious, Elizabethan. The qualities implied by these epithets are the reverse of those which should distinguish a translator of Homer; but setting this apart, and considering the poems as in the main original works, the superstructure of a romantic poet on the submerged foundations of Greek verse, no praise can be too warm or high for the power, the freshness, the indefatigable strength and inextinguishable fire which animate this exalted work."

On the great qualities of his tragedies and comedies Swinburne wrote: "The most notable examples of his tragic work are comprised in the series of plays taken, and adapted sometimes with singular licence, from the records of such parts of French history as lie between the reign of Francis I. and the reign of Henry IV., ranging in date of subject from the trial and death of Admiral Chabot to the treason and execution of Marshal Biron. The two plays bearing as epigraph the name of that famous soldier and conspirator are a storehouse of lofty thought and splendid verse, with scarcely a flash or sparkle of dramatic action. The one play of Chapman's whose popularity on the stage survived the Restoration is *Bussy d'Ambois* (d'Amboise)—a tragedy not lacking in violence of action or emotion, and abounding even more in sweet and sublime interludes than in crabbed and bombastic passages. His rarest jewels of thought and verse detachable from the context lie embedded in the tragedy of *Caesar and Pompey*, whence the finest of them were first extracted by the unerring and unequalled critical genius of Charles Lamb. In most of his tragedies the lofty and labouring spirit of Chapman may be said rather to shine fitfully through parts than steadily to pervade the whole; they show nobly altogether as they stand, but even better by help of excerpts and selections. But the excellence of his best comedies can only be appreciated by a student who reads them fairly and fearlessly through, and, having made some small deductions on the score of occasional pedantry and occasional indecency, finds in *All Fools*, *Monsieur d'Olive*, *The Gentleman Usher*, and *The Widow's Tears* a wealth and vigour of humorous invention, a tender and earnest grace of romantic poetry, which may atone alike for these passing blemishes and for the lack of such clear-cut perfection of character and such dramatic progression of interest as we find only in the yet higher poets of the English heroic age."

The list of the principal plays of George Chapman is as follows:

The Blinde Begger of Alexandria . . . (acted 1596, printed 1598), a popular comedy; *An Humorous dayes Myrth* (May 1597; printed 1599); *Al Fooles, A Comedy* (1599, if it may be taken as identical with a play entered by Henslowe as "The World runs on wheels," printed 1605); *The Gentleman Usher* (c. 1601, pr. 1606), a comedy; *Monsieur d'Olive* (1604, pr. 1606), one of his most amusing and successful comedies; *Eastward Hoe* (1605), written in conjunction with Ben Jonson and John Marston, an excellent comedy of city life; *Bussy d'Ambois, A Tragedie* (1604, pr. 1607, 1608, 1616, 1641, etc.), the scene of which is laid in the court of Henry III.; *The Revenge of Bussy d'Ambois, a Tragedie* (pr. 1613, but probably written much earlier); *The Conspiracie, And Tragedie of Charles Duke of Byron, Marshall of France . . . in two plays* (1608; pr. 1608 and 1625), severely cut after its first performance, which provoked a lively protest from the French ambassador; *May-Day, A witty Comedie* (pr. 1611, but probably acted as early as 1601); *The Widdowes Teares. A Comedie* (pr. 1612; produced perhaps as early as 1605); *Caesar and Pompey* (pr. 1631), written, says Chapman in the dedication, "long since," but never staged.

In *The Tragedie of Chabot Admirall of France* (c. 1613; pr. 1639) he collaborated with James Shirley, and in *Eastward Hoe* (1605, pr. 1605), with Jonson and Marston. *The memorable Masque of the two Honourable Houses or Inns of Court*, was performed at court in 1613 in honour of the marriage of the Princess Elizabeth.

The standard edition of Chapman is the *Works*, edited by R. H. Shepherd (1874-75), the third volume of which contains an "Essay on the Poetical and Dramatic Works of George Chapman," by Swinburne, printed separately in 1875. The selection of his plays (1895) for the Mermaid Series is edited by W. L. Phelps. The edition by T. M. Parrott (1910-14) includes *Alphonsus, Emperor of Germany*, and other plays sometimes attributed to Chapman. For the sources of the plays see Emil Koepfel, "Quellen Studien zu den Dramen George Chapman's, Philip Massinger's und John Ford's," in *Quellen und Forschungen zur Sprach und Kulturgeschichte* (vol. 82, Strassburg, 1897). The suggestion of W. Minto (see *Characteristics of the English Poets*, 1885) that Chapman was the "rival poet" of Shakespeare's sonnets is amplified in A. Acheson's *Shakespeare and the Rival Poet* (1903). For the relations between Shakespeare and Chapman, see also J. M. Robertson, *Shakespeare and Chapman* (1917).

For other criticisms of his translation of Homer see Matthew Arnold, *Lectures on translating Homer* (1861), and Dr. A. Lohff, *George Chapman's Ilias-Übersetzung* (1903).

CHAPMAN, one who buys or sells, a trader or dealer, especially an itinerant pedlar. The word "chap," now a slang term, meant originally a customer. The word chapman is from Mid. Eng. *cheap*, to barter, from which we get the name of the famous London thoroughfare "Cheapside."

CHAPONE, HESTER (1727-1801), English essayist, daughter of Thomas Mulso, a country gentleman, was born at Twywell, Northamptonshire, on Oct. 27, 1727. At the age of nine she wrote a romance entitled *The Loves of Amoret and Melissa*. While on a visit to Canterbury she met the learned Mrs. Elizabeth Carter, and then became one of the little court of women who gathered at North End, Fulham, around Samuel Richardson, and in Miss Susannah Highmore's sketch of the novelist reading *Sir Charles Grandison* to his friends Miss Mulso is the central figure. In 1760 Miss Mulso, with her father's reluctant consent, married the attorney, John Chapone, who had been befriended by Richardson. Her husband died within a year of her marriage. Her best known work, *Letters on the Improvement of the Mind* (1772) brought her numerous requests from distinguished persons to undertake the education of their children. She died on Dec. 25, 1801.

- See *The Posthumous Works of Mrs. Chapone, containing her correspondence with Mr. Richardson; a series of letters to Mrs. Elizabeth Carter . . . together with an account of her life and character drawn up by her own family* (4 vols. 1807).

CHAPPE, CLAUDE (1763-1805), French engineer, was born at Brûlon (Sarthe) in 1763. With his brother, Ignace (1760-1829), he was the inventor of an optical telegraph widely used in France until it was superseded by the electric telegraph. His device consisted of an upright post, on the top of which was fastened a transverse bar, while at the ends of the latter two smaller arms moved on pivots. The position of these bars represented words or letters; and by means of machines placed at such intervals that each was distinctly visible from the next, messages could be conveyed through 50 leagues in a quarter of an hour. The machine was adopted by the Legislative Assembly in 1792, and in the following year Chappe was appointed *ingénieur-télégraphe*; but the originality of his invention was so much ques-

tioned that he was seized with melancholia and (it is said) committed suicide at Paris, on Jan. 23, 1805.

CHAPPELL, WILLIAM (1800-1888), English writer on music, a member of the London musical firm of Chappell and Co., was born on Nov. 20, 1809, eldest son of Samuel Chappell (d. 1834), who founded the business. William Chappell deserves remembrance for having started the Musical Antiquarian Society in 1840 and for his *Popular Music of the Olden Time* (1855-59)—an expansion of a collection of "national English airs" made by him in 1838-40. The modern revival of interest in English folk-songs owes much to this work, which has since been re-edited by Professor H. E. Wooldridge (1893). His brother, Thomas Patey Chappell (d. 1902), started (1859) the Monday and Saturday Popular Concerts at St. James's Hall, which were successfully managed by a younger brother, S. Arthur Chappell, till they came to an end towards the close of the last century.

CHAPTAL, JEAN ANTOINE CLAUDE, COMTE DE CHANTELOUP (1756-1832), French chemist and statesman, was born in Nogaret, Lozère, on June 4, 1756. The son of an apothecary, he studied chemistry at Montpellier. In 1781 the States of Languedoc founded a chair of chemistry for him at the school of medicine in Montpellier, where he taught the doctrines of Lavoisier. The capital he acquired by the death of a wealthy uncle he employed in the establishment of chemical works for the manufacture of the mineral acids, alum, white-lead, soda and other substances. During the Revolution he undertook, in 1793, the management of the saltpetre works at Grenelle. In the following year he went to Montpellier, where he remained till 1797, when he returned to Paris. After the *coup d'état* of the 18th of Brumaire (Nov. 9, 1799) he was made a councillor of State by the First Consul, and succeeded Lucien Bonaparte as minister of the interior, in which capacity he established a chemical manufactory near Paris, a school of arts, and a society of industries; he also reorganized the hospitals and introduced the metric system of weights and measures. A misunderstanding between him and Napoleon (who conferred upon him the title of comte de Chanteloup) occasioned Chaptal's retirement from office in 1804; but before the end of that year he was again received into favour. On Napoleon's return from Elba, Chaptal was made director-general of commerce and manufactures and a minister of State. He contributed largely to the development of modern industry by the application of the science of chemistry to technical ends. Chaptal wrote many works on applied chemistry, and treatises on the technical aspects of the dyeing industry, etc. He died at Paris on July 30, 1832.

See *Mes souvenirs sur Napoléon*, ed. Vte. Anatole Chaptal (1893); W. Henning, *Die Erinnerungen des Grafen Chaptal an Napoleon I.* (1908).

CHAPTER, a principal division or section of a book, and so applied to acts of parliament, as forming "chapters" of the legislation of a session. The name is also given to the permanent body of canons of a cathedral or collegiate church and to the meetings of the monks of a particular monastery ("conventual") or of the members of the order in a province ("provincial"), or of the whole order ("general"). This use of the word is said to be derived from the custom of reading a chapter of the *regula* at such meetings. The title "chapter" is similarly used of the assembled body of knights of a military or other order. Chapter is a shortened form of *chapiter*, a word still used in architecture; Fr. *chapitre*, Lat. *capitulum*, diminutive of *caput*, head. (See also CANON; CATHEDRAL; DEAN.)

CHAPTER-HOUSE, the chamber in which the chapter or heads of the monastic bodies (see ABBEY and CATHEDRAL) assemble to transact business. They are of various forms; some are oblong apartments, as Canterbury, Exeter, Chester, Gloucester, etc.; some octagonal, as Salisbury, Westminster, Wells, Lincoln, York, etc. That at Lincoln has ten sides, and that at Worcester is circular; most are vaulted internally and polygonal externally, and some, as Salisbury, Wells, Lincoln, Worcester, etc., depend on a single slight vaulting shaft for the support of the massive vaulting. They are often provided with a vestibule, as at Westminster, Lincoln and Salisbury, and are almost exclusively Eng-

lish. On the continent of Europe the chapter-house is universally rectangular, and frequently of great size and dignity.

In the United States the word chapter-house refers almost invariably to the campus meeting or residence halls of the members of the collegiate Greek letter societies—fraternities or sororities with names chosen from various combinations of the Greek alphabet, as Delta Theta Psi, Sigma Alpha, etc.

CHAPU, HENRI (1833-1891), French sculptor and medalist, born in Le Mée (Seine et Marne) on Sept. 29, 1833. He studied at the École des Beaux-Arts under Pradier and Duret, and, having gained the Prix-de-Rome in 1855, spent five years in Rome. He was famous as a portrait medallist, and he executed many portrait busts and monuments; his statuary representing allegorical and mythological figures is sincere in feeling and poetical in conception.

His first success was attained by a figure of "Mercury" (1861, Luxembourg museum, Paris); then followed "The Sower" (1865); the "Nymph Clythia" (1866, Dijon museum). His fame was established by his statue of "Jeanne d'Arc" (1870, Luxembourg museum), representing her as a simple peasant kneeling in prayer. In 1872 Chapu undertook the monument to Henri Regnault with the fine figure of "Jeunesse" in the courtyard of the École des Beaux-Arts. In 1877 he sculptured the tomb of the Contesse Agoult (Daniel Stern) at Père Lachaise, and in 1887 he completed the monument to the archbishop Dupanloup. Among his portrait work may be mentioned Leon Bonnat (1864); Alexandre Dumas (1876); the bronze of J. E. Schneiders (1878) at Le Creuzot; the monument to the Galignani brothers (1888), representing them in modern costume, which was then an innovation and excited much comment, and the bust of Alexandra, princess of Wales. The monument to Flaubert, with an allegorical figure of "Truth" is his last important work. Chapu died in Paris on April 21, 1891. The museums of Rouen and Bayonne contain a number of his drawings.

See O. Fidère, *Chapu, sa vie et son oeuvre* (1894).

CHAPU, a port of China on the north shore of Hangchow bay (30° 39' N., 121° 6' E.). It is built on a series of low hills and was long an out-port of Hangchow. Being the only possible harbour site on Hangchow bay near to Shanghai (50 m. distant), Chapu has possibilities of becoming a relief out-port for this, the commercial metropolis of China.

CHAPULTEPEC, a suburb, and ancient seat of the Montezumas, situated about two miles southwest of the City of Mexico. On its rocky heights stands the summer palace of the president of the republic, in which is housed also the National Military School. At the base of this rising ground which commands the surrounding country is located a famous grove of cypresses estimated to be some thousand years old. Upon this whole critical position was fought the last actual battle of the War between Mexico and the United States (1846-1848). Major General Winfield Scott after the disaster of El Molino del Rey found that he had available about 7,000 badly shaken United States troops, far from their base and in the heart of a hostile country. Opposing him General Santa Anna, the president of the republic, controlled at least twice that number. The natural and artificial strength of the palace, its proximity to the American goal, and its meaning relative to governmental power, made its possession by the contending forces of the greatest moment. After several days of reconnaissance, feints and preparations, Scott decided that this stronghold between him and the capital must be taken.

On September 12, 1847, an all-day bombardment of the buildings, surrounding forts and redoubts convinced him of the necessity of an assault. During the following night both the American and Mexican batteries and positions were strengthened and Scott's plans for an attack in front and reverse were crystallized. Major General J. A. Quitman's troops were directed to advance to the rear of the palace by way of the Tacubaya road, whereas Major General G. J. Pillow's division was given the task of striking the front by way of El Molino del Rey and the cypress grove. From early dawn on September 13 until eight o'clock—about two hours and a half—the American guns hurled solid shot, grape, canister and shells at the barriers of stone and mortar. At the end of that

time the infantry went forward to the assault, the main blow being delivered by regular troops upon the Mexican points of vantage in the cypress grove. Lieutenant "Stonewall" Jackson, later of Civil War fame, handled on his own initiative a section of Magruder's field battery in such a manner as to cut off the northern retreat of the Mexican fugitives. The major portion of Scott's forces went forward doggedly under severe fire. Officers on both sides became casualties to a disproportionate degree. When the United States' troops finally reached the ditch they found there no ladders with which to scale the parapets. Although Brigadier General P. F. Smith gallantly led a turning movement toward the rear of the palace, he was met by such a galling fire that his losses, including the wounded Lieutenant James Longstreet, were sufficient to stop him.

The suspense and curtailment of enthusiasm among Scott's troops as they crouched behind any available cover, while waiting for the implements that would enable them to go over the top of the barrier, lent serious apprehensions as to the success of the American effort. When, after some twenty minutes, the ladders arrived, the previous restiveness reacted upon the men in the form of ardour to proceed. They swarmed over the parapets with such impetus that in a very few minutes of sharp hand to hand fighting Chapultepec was in their hands. Since its capture was but a means to an end, and the exploitation of the success involved the seizure of the City of Mexico itself, it was necessary to move onward immediately. Quitman set out over the Belen causeway toward the capital. After overwhelming a field redan in his front he came upon decided opposition at the gate which was protected by a formidable citadel beyond. From its embrasures belched a withering fire. Quitman's ammunition having been exhausted and all his staff officers having been killed or wounded, his position was not fortunate.

To check Mexican reinforcements, Scott sent Brigadier General Worth's brigade, together with some smaller units, along the Verónica causeway. Finding his advance likewise blocked by heavy fire, Worth sent Colonel John Garland's force through the fields to outflank the San Cosme gate which lay about a mile north of Quitman's troops. By crawling through mud, forcing their way through houses and using such cover as was available, in small bodies they reached the rear of the position. During this procedure, Lieutenant U. S. Grant had a mountain howitzer dragged through the mud and mounted upon the roof of a building. About six o'clock in the evening Worth forced an entrance into the city proper, and shortly activities ceased for the night. Though the capital was not yet under American control, General Santa Anna chose to retire with his forces to Guadalupe Hidalgo. Next morning when Scott was ready to renew hostilities, the City of Mexico was unexpectedly surrendered.

CHAR, the name given to fishes of the genus *Salvelinus*, which differs from *Salmo* (salmon and trout) in having the vomerine teeth present only on the head of the bone, which is raised and has a boat-shaped depression behind it. *Salvelinus alpinus* of the Arctic ocean is a marine fish that enters rivers to breed and may form freshwater colonies, especially in lakes. It is represented by many isolated colonies in lakes that it entered in glacial times, far to the south of its present range in the sea, in Scandinavia and the Alps, in Scotland, Ireland and the Lake District of England, and in North America. Many of these lacustrine forms differ considerably from the northern migratory char, and have been described as distinct species; they are more or less similar to trout, but have smaller scales and are generally beautifully coloured—bluish or olive above, often with bright orange spots on the sides; the belly varies from pink to scarlet, the coloration being most intense in the breeding males. The migratory fish are silvery, with the spots inconspicuous. *Salvelinus fontinalis*, the brook trout of eastern North America, is mainly a river fish, distinguished by the blackish mottling of the back and the dorsal and

caudal fins; sea-run individuals (the Canadian "salmon trout") are plain silvery. *Salvelinus namaycush*, the Great Lake trout of North America, is a grayish fish with dark markings on the dorsal and caudal fins; it is distinguished from other char by the widely forked caudal fin; it reaches a weight of 100 pounds.

(C. T. R.)

CHARABANC, a large form of wagonette-like vehicle for passengers, but with benched seats arranged in rows, looking forward, commonly used for large parties, whether as public conveyances or for excursions. The word is French for benched carriage; in the English motor trade the term "motor coach" is preferred.

CHARACTER. To ask what character is, reveals the confusion of ordinary thought about it. Instincts, habits, impulses, desires, emotions, sentiments all belong to it. But what relation do they bear to one another? What is the part of character that has to be controlled and what is its controlling part? Whence come those things that are called "principles" of conduct, and "ideals," and the multitude of "qualities of character"—courage, steadfastness, sincerity, tolerance, generosity, patience and honesty and their opposites? We do not know. The first general problem of the psychology of character is therefore to transform the chaos of the ordinary conception of it into one in which the parts of character are seen to bear a clear and intelligible relation to the whole.

There are certain common but useful antitheses "character and intelligence"; "character and circumstances"; "character and conduct." Conduct is the expression of character; only actions that are in some degree under voluntary control are included in conduct. Reflex actions are not included in conduct; instinctive actions are. Character is the driving force; intelligence guides it to its destination; together they sum up the human mind and are inseparable in it.

Stages of Character.—These may be classed under three heads, which roughly correspond to three levels of mental development: (1) the instinctive; (2) the emotional; (3) the level of sentiment; and again roughly these three are represented in (1) the life of the animal; (2) the life of the child; and (3) the life of the adult human being. The first is the most perfect in organization; but also the most rigid, in which intelligence has least formative influence. The second is the most helpless and marks the transition from a lower to a higher form of organization, for which the guidance of the adult mind is indispensable. The third is the most plastic and comprehensive; but its organization is never completed. In it reflection, reason and self-control have their full opportunities; yet it is the region of folly and error, with which we can hardly charge the animals; of mistaken valuations followed by disillusionings; of progress and decadence; of constancy and infidelity. It has never been understood.

The Human Instincts.—Animal instincts are inherited dispositions having specific patterns of behaviour for the attainment of their ends. An impulse felt in consciousness precedes their operation; attention accompanies it, and serves to adapt the pattern of behaviour to the actual situation. Human instincts have lost these patterns except in the case of simple instincts, as sucking, shrinking and clinging; in others the child must learn by experience to acquire new means to replace the old. The end for an animal is perceived—a hole or cover; the end for man may be conceived—a secret thought. In this sense, as instinctive impulses defined by their ends, we can enumerate the most important human instincts. They are flight and pursuit, concealment and display, domination and submission, attraction and repulsion, destruction and construction, crying for protection and giving protection, curiosity and search, and the food and sex instincts. The ends are only proximate ones, assumed to have been selected first for their biological utility; but in man they are also indispensable to the ends which he invents—wealth, power, fame, well-being, happiness, perfection.

The instincts sometimes act independently of emotion, finding in their own impulses when unchecked the force to attain their ends; but (1) when their impulses are obstructed they tend to arouse anger or fear; (2) when they attain their ends, joy or

satisfaction; (3) when they fail completely, sorrow or despair. The emotions never act independently of instincts, and tend to organize in their systems all that subserve their ends. Hence we find concealment not only in fear, but in the anger of revenge; in shame; in envy; in sorrow; in the joy of children's games. This seems to be the relation between instincts and emotions.

Difference Between Instinct and Emotion.—An instinct advancing to its end unchecked does not need to arouse emotion. In itself it is unlike emotion; it is most like habit. Both instinct and habit are orderly and stable, showing so little variability in action that we forecast the course of it. Emotion unrestrained is unstable and disorderly; its actions often surprise us. We follow our strong habits often without recognizing them; they are calm and unobtrusive; we cannot help recognizing our strong emotions. Hence it is, when emotion and instinct are conjoined, the second as it comes into operation tends to calm the first. It is the moments before action, we remark, that are so tense. For the force which emotion brings is for the needs of a certain situation. It should not therefore persist for long, and if it does, it tends to become pathological, as we see in the case of our morbid fears.

Besides these differences between instincts and emotions there are those based on the nature of their systems. Emotion is potentially more complex. Concealment is only one of many instincts organized in fear which may choose this instinct or any other better adapted to the actual situation: flight, shrinking or clutching, or shrieks for protection. From the time of Bain it has been recognized that strong emotion is accompanied by a diffused nervous disturbance; and this may render emotion more adaptable to a changing situation; whereas when an instinct is unchecked, and following out the normal course of its behaviour, the nervous discharge tends to be restricted to those channels which sustain this behaviour. Here the intervention of emotion would be not only superfluous but harmful.

The value of emotion lies in these two points of difference from instinct: (1) the force which it brings to deal with a given situation, and (2) its potentially more complex and adaptable system. It is indispensable to the sentiments, and without it there could neither be love nor hate. All great changes of character are initiated by emotion.

The Stage of the Sentiments.—That which has to exercise control must have a wider outlook than that which is to be controlled; but unless it moves us its warnings are ineffectual. It must move us by some other influence than emotion. Self-control comes from a higher system than emotion, and one that by its comprehensiveness more adequately represents the self. Love and hate, the chief sentiments, have this comprehensiveness. They are that governing part of character to which we have referred; and all the part which has to be governed is beneath them, under their authority. Love obtains its great organizing desires directed to its unchanging ends of union, happiness and well-being of the loved object, reciprocity of love, and the desire to be happy in the love of the object. But in hate these ends are reversed: not preservation and union, but destruction and separation; not happiness and well-being, but misery and the worst possible state of the object, and yet withal, the desire to be happy in the separation, misery and destruction of the object.

In these great desires love and hate find the principles of their self-control—not in their emotions.

Repression.—Repression is an extreme form of the self-control of sentiments. For if some of their emotions have to be regulated as being either too strong or too weak, others which are judged to be harmful in view of their ends have to be repressed. Such repression of things within the mind corresponds most nearly to "destruction" of things without us. We would destroy some things in our character if we could; but we can only repress them, which means to exclude them from consciousness, and prevent as far as possible their return to it.

Conscience.—There is another sentiment distinct from both love and hate, which, like them, often undergoes repressions. The uniqueness of conscience makes it difficult to interpret, for there is a particular conscience belonging to all love of which its ideals are a part. This is partial to the loved object; it is the

repository of that part of the moral beliefs of the community in which the individual has been instructed and which he has adopted through authority and suggestion. It is therefore apt to differ from one person to another. But when it is a living force of character, it grows with a man's experience of life, and through the illusions and disappointments of love. These impress certain ideals and duties upon his mind differently from hearsay, however often repeated. They become the most vital part of his conscience, being there freed from the partiality to which love at first confined them. And as the ideals of love are much the same in its different varieties, the most general and important duties come to be impressed, sooner or later, on most men.

Thus is shown in merest outline how the parts of character are related to one another and the whole—how the instincts, habits, emotions and desires function in the sentiments of man, and there represent the unity of his character. Yet how incompletely they represent it. The potentials of his character transcend for better and worse everything that he has drawn from them to build up his actual loves and hates, and remain a perpetual enigma to him. The word is also applied to symbols of notation; letters of the alphabet, and, more particularly to ideographs; in such phrases as "the characters of the Chinese language number nearly 50,000." By extension of the philosophical meaning a "character" has almost become synonymous with "reputation." Still further development of this idea is found in the description of a person as "a character" ("an odd or eccentric person").

BIBLIOGRAPHY.—A. Bain, *The Study of Character* (1861); A. F. Shand, *Foundations of Character* (1914); A. A. Robaek, *The Psychology of Character* (1927); Theophrastus' *Characters*, contains the oldest extant sketches of types of character. (A. F. S.)

CHARADE, a kind of riddle, probably invented in France during the 18th century, in which a word of two or more syllables is divined by guessing and combining into one word (the answer) the different syllables, each of which is described, as an independent word, by the giver of the charade. Charades may be either in prose or verse. Of poetic charades those by W. Mackworth Praed are well known and excellent examples, while the following is a good specimen in prose. "My first is company; my second shuns company; my third collects company; and my whole amuses company." The solution is *Co-mun-drum*. The most popular form of this amusement is the acted charade, in which the meaning of the different syllables is acted out on the stage, the audience being left to guess each syllable and thus, combining the meaning of all the syllables, the whole word. A brilliant description of the acted charade is given in Thackeray's *Vanity Fair*.

CHARADRIIDAE: see LAPWING; PLOVER; TURNSTONE.

CHARADRIIFORMES, an order of birds, also called Limicolae, most members of which are shore haunting waders. The young are active and down-clad at hatching. See ORNITHOLOGY, CURLEW, PHALAROPE, PLOVER, SHEATHBILL, SNIPE, WOODCOCK.

CHARCOAL. Charcoal is the residue obtained when carbonaceous materials, of either animal or vegetable origin, are partially burned or heated so that the tarry and volatile matter is removed: in most cases the residues may be roughly described as impure carbon (*q.v.*). The same process of "carbonization" or "destructive distillation" is applied to coal in the manufacture of ordinary illuminating gas, but the residue obtained in this case is termed "coke."

It is customary to speak of "animal charcoal," "sugar charcoal" and "wood charcoal," the origin of the material being indicated in this way. The first of these products is obtained by strongly heating blood or bones, and accordingly may be either "blood charcoal" or "bone charcoal." Since bones consist very largely of phosphate of lime and other inorganic constituents which are not driven off on heating, bone charcoal contains relatively little carbon—only about 10–12% deposited in a finely divided state over the surface of the inorganic material.

Of the various charcoals, that obtained from sugar most nearly approaches pure carbon, and on this account is of considerable scientific interest, although of minor significance from the indus-

trial standpoint. When carefully prepared from pure sugar, it is practically free from inorganic constituents, and, accordingly on burning, leaves behind a negligible proportion of ash.

Wood Charcoal.—Wood charcoal is a material the production of which has been practised for centuries in regions where timber is abundant. The old procedure consisted in building the cut wood into heaps or stacks with a vent in the middle, and then setting it alight. The heat developed by the combustion of part of the wood served to carbonize the remainder, the extent of the combustion being limited by controlling the access of air and by covering the stack with moist turf or soil. In modern methods, on the other hand, the wood is heated in retorts, and this procedure makes possible the recovery of certain valuable by-products, such as wood tar, acetone, wood spirit and acetic acid.

The proportion of charcoal obtainable from wood is roughly about one-quarter of the *weight* of the wood, varying naturally with the method of carbonization employed. The relative reduction in volume, however, is not so great, for wood charcoal is an extremely porous material, and its bulk is approximately two-thirds of the bulk of the wood from which it has been prepared.

The composition and properties of the product depend on the temperature of carbonization. The higher the temperature and the longer the duration of carbonization, the greater is the proportion of carbon in the charcoal obtained, and by protracted treatment at a red heat the proportion of hydrogen may be reduced to a comparatively small figure. A charcoal, for example, obtained by heating birch wood for six hours at 750° C was found to contain only 0.5% of hydrogen. The amount of ash left on the complete combustion of wood charcoal varies with the wood employed and with the conditions of its carbonization, but is generally not more than 2–3%.

Charcoal was originally produced mainly for use as fuel. Since during carbonization the bulk of the tarry and volatile matter is driven off, charcoal is a clean fuel, and the heat given out in the combustion of a fixed weight—the so-called calorific value—is twice as great for charcoal as for the original wood. While charcoal prepared at a high temperature is difficult to ignite, the product obtained by carbonization at, say, 300° C, retaining a considerable proportion of volatile inflammable matter, it ignites readily.

In earlier days large quantities of wood charcoal were prepared for the reduction of iron from its ores, an operation in which coke is now mainly employed. So great was the demand for charcoal where iron ores were found that serious inroads were made on the timber in these districts. This was the case, for example, in the county of Sussex, where at one time the smelting of iron was extensively practised.

Another purpose for which wood charcoal has been required in large quantities is the manufacture of gunpowder. The constituents of this material are nitre, sulphur and charcoal, and the last-mentioned ingredient is obtained by the carbonization, at a fairly low temperature, of certain light woods, such as alder and willow.

Wood charcoal or charred wood differs from ordinary wood in exceptional resistance to decay—a characteristic which was known to the ancients. Some time ago a quantity of oak stakes were found in the bed of the river Thames at the spot where, according to Tacitus, the Britons fixed a vast number of such stakes in order to oppose the passage of a Roman army. These stakes, which were found to be charred superficially, had retained their form, and were sound at the heart. In this connection it is further noteworthy that the wooden piles on which many Venetian houses stand have all been charred in order to secure their preservation.

An extremely interesting property of charcoal is its power of adsorbing gases and of removing colouring matters from solution. It has long been known that charcoal will take up many times its own volume of a gas—in the case of ammonia 100–200, and at a low temperature its adsorptive capacity is very strikingly increased. Dewar found, for example, that the amount of nitrogen taken up by a certain charcoal was ten times as great at –185° C as at 0° C. This fact has been utilized in the production of high vacua. Freshly prepared charcoal, when exposed to air, gradually takes up water vapour and increases notably in weight—a further

illustration of the adsorptive properties of this material.

Equally remarkable is the ability of charcoal to remove colouring matters from solutions, a property discovered more than 100 years ago and applied first in the treatment of beet-sugar juice. Coloured solutions, such as red wine or indigo, when treated with animal charcoal and then filtered, yield colourless liquids.

Activated Charcoal.—In recent years there have been notable developments in the applications of wood charcoal, dating back mainly to the World War of 1914–18. On the introduction of gas warfare in 1915 it became an urgent necessity to provide every soldier with some form of protection, and before long charcoal was generally adopted as an adsorbent for this purpose. Animal charcoal was first employed, since this material, according to a commonly accepted view, was more efficient than wood charcoal for absorbing gases. On grounds of economy, however, it was desired to use the latter material if possible, and investigations soon showed that when ordinary wood charcoal is kept for some time at a red heat with limited access of air, its power of absorbing gases is increased in a quite remarkable degree. It is said to be “activated.”

It is worth while giving a few details in order to emphasize this marked effect of the “heat treatment” of wood charcoal. The efficiency of a particular birch-wood charcoal was tested by exposing a sample to a “dose” of poison gas. The material proved to be comparatively inefficient, retaining only 80% of the poison gas. The charcoal was then heated for 8 hours at 925° C with limited access of air, and a specimen of the product was tested in exactly the same way, showing a very different result, for the charcoal now adsorbed completely *four* consecutive doses, and retained even the half of a fifth dose.

The respirators supplied to the troops of all countries in the later stages of the war contained activated charcoal. Similar or even greater improvement in absorptive power can be achieved by heating wood charcoal in carbon dioxide or superheated steam, while impregnation with certain chemicals, such as zinc chloride, sulphuric acid or phosphoric acid, followed by exposure for some time to a high temperature, also yields an “active” product. This increase in absorptive capacity has been the subject of much investigation, and it appears that heat treatment such as that described augments the available surface of the charcoal. Activation is accompanied by a decrease of the bulk density, that is, a given weight of charcoal occupies more space after activation than it did before: its porosity is greater. It is probable also that the carbon molecules themselves undergo some modification on heating.

Activated charcoals are also of great importance from the industrial standpoint, more especially in connection with the adsorption of hydrocarbons such as gasoline, and the decolorizing of sugar juices. The well-known commercial materials, “Eponit” and “Norit,” may be quoted as examples of these products, and evidence of the industrial significance of active charcoals is furnished by the numbers of fresh patents taken out for their manufacture from all sorts of vegetable substances. (*See ADSORPTION.*) (J. C. P.)

CHARCOT, JEAN MARTIN (1825–1893), French physician, was born in Paris on Nov. 29, 1825. In 1853 he took his M.D. at Paris, and three years later was appointed physician of the Central Hospital Bureau. In 1860 he became professor of pathological anatomy in the medical faculty of Paris, and in 1862 began his famous connection with the Salpêtrière where he created the greatest neurological clinic of modern times. As regards hysteria, which he defined as a psychosis superinduced by ideation, he threw the sexual theory into disrepute and studied the disease in relation to hypnotism. In muscular atrophy he differentiated between the ordinary wasting and the rarer amyotrophic lateral sclerosis (1874) and described with Pierre Marie the progressive neural or peroneal type (1886). He differentiated the essential lesions of locomotor ataxia and described both the gastric crisis and the joint affections (Charcot's disease). He separated multiple sclerosis from paralysis agitans. In diseases of the brain, the most notable contributions were his articles on

cerebral localization, the studies of aphasia and the discovery of the military aneurisms and their importance in cerebral haemorrhage. He also published writings on senile diseases, liver and kidney diseases, gout, chronic pneumonia and tuberculosis. Charcot greatly promoted the study of medicine in art (see: *Nouvelle Iconographie de la Salpêtrière*, 1888). He died on Aug. 16, 1893.

His best known works are *Leçons sur les maladies du système nerveux*, 5 vols. (1872-93) and *Leçons du mardi à la Salpêtrière*, 2 vols. (1889-90).

See F. Garrison, *Hist. of Medicine*, 3rd ed. (1921), and W. Osler memorial notice in *Johns Hopkins Hospital Bulletin* (1893).

CHARD, JOHN ROUSE MERRIOTT (1847-1897), British soldier, was born at Boxhill, near Plymouth, on Dec. 21, 1847, and in 1868 entered the Royal Engineers. In 1878 Lieut. Chard was ordered to South Africa to take part in the Zulu War, and was stationed at the small post of Rorke's Drift to protect the bridges across the Buffalo river and some sick men and stores. Here, with Lieut. Gonville Bromhead (1856-91) and 80 men of the 2nd 24th Foot, he conducted the gallant defence of Rorke's Drift against 3,000 Zulus, which saved Natal from a Zulu invasion. The gallantry of Chard and Bromhead was rewarded with the V.C. and immediate promotion to the rank of captain and brevet-major. Chard was made colonel in 1897. He died the same year at Hatch-Beauchamp, near Taunton, on Nov. 1.

CHARD, a market town and municipal borough in the Yeovil parliamentary division of Somersetshire, England, 12 m. S.S.E. of Taunton. Pop. (1931) 4,053. It stands on high ground within 1 m. of the Devonshire border with railway stations S.R. (Chard Town) and G.W.R. (Chard Joint Station). Chard (*Cerdre*, *Cherdre*, *Cherde*) was originally a trade centre near the Roman road to the west. There are two Roman villas in the parish. The bishop of Bath held Chard in 1086, and in 1234 his successor granted the first charter which made it a free borough. This charter was confirmed in 1253, 1280 and 1285. Chard is said to have been incorporated by Elizabeth, as the corporation seal dates from 1570. It was incorporated by grant of Charles I. in 1642, and Charles II. gave a charter in 1683. A market on Mondays and fair on July 25 were granted in 1253, and confirmed in 1642 and 1683, when two more fair days were added (Nov. 2 and May 3). The market day is now Monday, fairs being held on the first Wednesday in May, August and November, for corn and cattle only, their mediaeval importance as centres of the cloth trade having departed. The cruciform parish church of St. Mary the Virgin is Perpendicular of the 15th century. A fine east window is preserved. The manufactures include lace and other textiles.

CHARD or SWISS CHARD, a name given to the edible leaf-beet (*Beta vulgaris* var. *Cichla*), a variety of the beet (*q.v.*) in which by long cultivation the leaves and leaf-stalks, instead of the roots, have become greatly developed. The plant is a biennial with somewhat branched and thickened but not fleshy roots, and large leaves borne on stalks sometimes 2 ft. long and 1 in. to 3 in. thick. It is grown for the tender leaves and leaf-stalks; the former are boiled and served like spinach, the latter, like asparagus. The leaves and leaf-stalks of the artichoke (*q.v.*), when made tender by blanching, are likewise called chard.

CHARDIN, JEAN SIMÉON (1699-1779), French *genre* painter, the son of Jean Chardin, master-carpenter, was born in Paris on Nov. 2, 1699, and died Dec. 6, 1779. He became famous for his still-life pictures and domestic interiors, which are well represented at the Louvre, and for figure-painting, as in his *Le Bénédicité* (1740) and is acknowledged as one of the greatest colourists of the French school. Many of his most notable pictures are in the collection of Baron Henri de Rothschild.

See A. Dayot, *J. B. Siméon Chardin* (1905); H. E. A. Furst, *Chardin* (1911); E. Pilon, *Chardin* (1911).

CHARDIN, SIR JOHN (1643-1713), French traveller, was born in Paris in 1643. In 1665 he set out for Persia and India. He returned in 1670 and published *Récit du Couronnement du roi de Perse Soliman III.* in 1671. In Aug. 1671 he left again for Persia, going by Smyrna, Constantinople, the Crimea, Caucasus, Mingrelia and Georgia, and reached Ispahan in June 1673. He

spent four years in Persia, visited India, and returned by the Cape of Good Hope in 1677. In 1681 the persecution of Protestants drove him to London, and in 1683 he went to Holland as representative of the East India Company. In 1686 he published the first part of *The Travels of Sir John Chardin*, etc. He died in 1713 and was buried in Westminster Abbey.

BIBLIOGRAPHY.—The complete account of Chardin's travels appeared at Amsterdam in 1711, under the title of *Journal du voyage du chevalier Chardin*. The Persian portion is to be found in vol. ii. of Harris's *Collection* (1705), and extracts are reprinted by Pinkerton in vol. ix. The best complete reprint is by Langlès (1811).

CHARENTE, an inland department of south-western France, comprehending the ancient province of Angoumois, and small portions of Saintonge, Poitou, Marche, Limousin and Périgord. It is bounded north by the departments of Deux-Sèvres and Vienne, east by those of Haute Vienne and Dordogne, south by Dordogne and Charente-Inférieure, and west by Charente-Inférieure. Area 2,305 square miles. Pop. (1926) 312,790. The Confolentais (known also as the *Terres Froides*) in the north-east is a region of granitic rocks which may be considered as a western extension of the Plateau Central. Here some parts exceed 1,000 ft. in height and the whole provides good upland pasture for cattle. The remainder of the department, known as the *Terres chaudes*, consists of Jurassic, Cretaceous and Tertiary deposits and provides rich arable land. Cereals and potatoes are the principal crops and chestnuts, walnuts and cider-apples the chief fruits. The *Terre Champagne* is noted for its vines, much of the wine produced being distilled into brandy named after the town of Cognac. A large area drains to the river Charente, the chief affluents of which, in this section, are the Tardoire, the Touvre and the Né. The Confolentais is watered by the Vienne, a tributary of the Loire, while the district of Barbezieux, noted for its poultry farming, belongs almost wholly to the basin of the Gironde.

Charente has stone quarries, peat workings and beds of clay which supply brick and tile-works and earthenware manufactories. There is a large foundry of naval guns at Ruelle. Flour-mills and leather-works are numerous. Angoulême is a paper-making centre and manufactures gunpowder. Coal, salt and timber are prominent imports. Exports include paper, brandy, stone and agricultural products. The department is served chiefly by the Orléans and Ouest-État railways, and the Charente is navigable below Angoulême. Charente is divided into the three *arrondissements* of Angoulême, Cognac and Confolens (29 cantons, 426 communes). It belongs to the region of the XII. army corps, to the province of the archbishop of Bordeaux, and to the *académie* (educational division) of Poitiers. Its court of appeal is at Bordeaux.

Angoulême (*q.v.*) is the capital and Cognac, Confolens, Jarnac, and La Rochefoucauld are other towns (*qq.v.*). The department abounds in churches of Romanesque architecture, of which those of Bassac, St. Amant-de-Boixe (portions of which are Gothic in style), Plassac and Gensac-la-Pallue may be mentioned. There are remains of a Gothic abbey church at La Couronne, and Roman remains at St. Cybardeaux, Brossac and Chassenon (where there are ruins of the Gallo-Roman town of Cassinomagus).

CHARENTE-INFÉRIEURE, a maritime department of south-western France, comprehending the old provinces of Saintonge and Aunis, and a small portion of Poitou, and including the islands of Ré, Oléron, Aix and Madame. Area, 2,791 sq. miles. Pop. (1926) 417,789. It is bounded north by Vendée, north-east by Deux-Sèvres, east by Charente, south-east by Dordogne, south-west by Gironde and the estuary of the Gironde, and west by the Bay of Biscay. The department is low-lying and consists of Jurassic, Cretaceous, Tertiary and Quaternary deposits which run in a north-westerly direction. This trend can be traced also in many sections of the coast and in the islands of Oléron and Ré. Post-Pleistocene submergence has resulted in the formation of many inlets and estuaries, particularly the Gironde, and there are several good harbours, the chief of which are La Rochelle and Rochefort. The latter has developed at the expense of Tonnay-Charente which is too high up the river to cope with modern shipping. Oysters and mussels are bred in the neighbourhood of La Rochelle and Marennes and there are many fishing villages. Royan, on the north shore of the Gironde, is a much-frequented

watering-place. The chief crops are wheat, oats, maize, barley and potatoes. Horse and cattle-raising is carried on and dairying is prosperous. A considerable quantity of wine, most of which is distilled into brandy, is produced. The department has a few peat-workings, and produces freestone, lime and cement; the salt-marshes of the coast are important. Ship-building, iron-founding, machine construction and the making of glass, pottery, bricks and earthenware are also carried on. The railways traversing the department belong to the Ouest-État system, except one section of the Paris-Bordeaux line belonging to the Orléans Company. Internal communication is facilitated by the navigable reaches of the Charente, the Sèvre Niortaise, the Boutonne, the Seudre and the Gironde and by the canals of the coast. There are four arrondissements (40 cantons, 482 communes), cognominal with the towns of La Rochelle, Rochefort, Saintes and Jonzac. The department forms the diocese of La Rochelle, and is attached to the 18th military region, and in educational matters to the *académie* of Poitiers. Its court of appeal is at Poitiers.

La Rochelle, St. Jean d'Angély, Rochefort and Saintes are the principal towns. Surgères and Aulnay possess fine Romanesque churches. Pons has a château of the 15th and 16th centuries and a keep of the 12th century.

CHARENTON-LE-PONT, a town of northern France in the department of Seine, situated on the right bank of the Marne, at its confluence with the Seine. Pop. (1926) 20,340. *Le Pont* refers to the stone bridge of ten arches which crosses the Marne and unites the town with Alfortville, well known for its veterinary school founded in 1766. In the 16th and 17th centuries Charenton was the scene of the ecclesiastical councils of the Protestant party, which had its principal church in the town. At the neighbouring St. Maurice is the well known Hospice de Charenton. Charenton has a port on the Canal de St. Maurice, beside the Marne, and carries on boat-building and the manufacture of tiles and porcelain.

CHARES, of Lindus in Rhodes, a sculptor pupil of Lysippus, who fashioned for the Rhodians a colossal bronze statue of the sun-god, the cost of which was defrayed by selling the warlike engines left by Demetrius Poliorcetes after the siege in 303 B.C. (Pliny, *Nat. Hist.* xxxiv. 41). The colossus was seventy cubits (105ft.) in height. The notion that it bestrode the harbour is absurd. It was thrown down by an earthquake after 56 years.

See E. A. Gardner, *Handbook of Greek Sculpture* (1915), § 61.

CHARES, of Mytilene, a Greek belonging to the suite of Alexander the Great, to whom he was appointed court-marshal. He wrote a history of Alexander in ten books, dealing mainly with the private life of the king. The fragments are chiefly preserved in Athenaeus.

See *Scriptores Rerum Alexandri* (pp. 114-20) in the Didot edition of Arrian.

CHARES, Athenian general, is first heard of in 366 B.C. as assisting the Phliasians against Argos and Sicyon. In 361 he helped the oligarchs at Corcyra to expel the democrats. In 357 he was appointed to the command in the Social War, together with Chabrias, after whose death before Chios he was associated with Iphicrates and Timotheus (for the naval battle in the Hellespont, see TIMOTHEUS). Chares, having successfully thrown the blame for the defeat on his colleagues, was left sole commander, but receiving no supplies from Athens, joined the revolted satrap Artabazus. A complaint from the Persian king led to the conclusion of peace (355) between Athens and her revolted allies, and the recall of Chares. In 349, he was sent to the assistance of Olynthus (*q.v.*) against Philip II. of Macedon, but effected nothing. In 340 he was appointed to the command of a force sent to aid Byzantium against Philip, but the inhabitants, remembering his former plunderings and extortions, refused to receive him. In 338 he was defeated by Philip at Amphissa, and was one of the commanders at the disastrous battle of Chaeroneia (*q.v.*). After the conquest of Thebes by Alexander (335), Chares is said to have been one of the Athenian orators and generals whose surrender was demanded. Two years later he was living at Sigeum, Arrian (*Anabasis*, i. 12). In 332 he entered the service of Darius. He is last heard of at Taenarum, and is supposed to have died at

Sigeum. Chares was not lacking in personal courage, and was among the best Athenian generals of his time. At the best, however, he was "hardly more than an ordinary leader of mercenaries" (A. Holm).

See Diod. Sic. xv. 75, 95, xvi. 7, 21, 22, 85-88; Plutarch, *Phocion*, 14; Theopompus, *ap. Athenaeum*, xii. p. 532; A. Holm, *History of Greece* (Eng. trans., 1896), vol. iii.; *Cambridge Ancient History*, vol. vi. (1927), chapters viii. and ix. (with useful bibliography).

CHARGE, a load (Late Lat. *caricare*, to load in a *carrus* or wagon); *cf.* "cargo," "charger," a large dish. The word is used also for the powder and shot to load a firearm, the accumulation of electricity in a battery, the necessary quantity of dynamite or other explosive in blasting, and a device borne on an escutcheon in heraldry. "Charge" can mean a burden, and so a care or duty laid upon one, as in the instructions given by a judge to a jury, or by a bishop to the clergy of his diocese. In the sense of a pecuniary burden the word is applied to the price of goods, to an encumbrance on property and the expense of running a business. Further uses of the word are of an attack by cavalry, or by a bull or elephant, or football player; "charger," originally a horse ridden in a charge, now means a horse ridden by an officer, whether of infantry or cavalry.

CHARGÉ D'AFFAIRES: see AMBASSADOR; DIPLOMACY.

CHARGER, a riding horse allotted to a military officer for war; any mechanism adapted for charging, as for placing explosives in bore-holes for blasting, and that used in loading a magazine rifle or a machine gun, etc.; a large shallow dish.

CHARGING ORDER: see PRACTICE AND PROCEDURE.

CHARIBERT (d. 567), king of the Franks, was the son of Clotaire I. On Clotaire's death in 561 his estates were divided between his sons, Charibert receiving Paris as his capital, together with Rouen, Tours, Poitiers, Limoges, Bordeaux and Toulouse. Besides his wife, Ingoberga, he had unions with Merofleda, a wool-carder's daughter, and Theodogilda, the daughter of a neatherd. He was one of the most dissolute of the Merovingian kings.

(C. Fr.)

CHARIDEMUS, of Oreus in Euboea, Greek mercenary leader. About 367 B.C. he fought under the Athenian general Iphicrates against Amphipolis, but later joined Cotys, king of Thrace, against Athens. Soon afterwards he fell into the hands of the Athenians and accepted the offer of Timotheus to re-enter their service. Having been dismissed by Timotheus (362) he joined the revolted satraps Memnon and Mentor in Asia; after more service under the Athenians, he again joined Cotys, on whose murder (360) he was appointed guardian to his youthful son Cersobleptes. In 357, on the arrival of Chares with considerable forces, the Chersonese was restored to Athens. The supporters of Charidemus represented this as due to his efforts, and, in spite of the opposition of Demosthenes, he was honoured with a golden crown and it was resolved that his person should be inviolable. In 351 he commanded the Athenian forces in the Chersonese against Philip II. of Macedon, and in 349 he superseded Chares as commander in the Olynthian War. He achieved little success, but made himself detested and was in turn replaced by Chares. After Chaeroneia the war party would have entrusted Charidemus¹ with the command against Philip, but the peace party secured the appointment of Phocion. He was one of those whose surrender was demanded by Alexander after the destruction of Thebes, but escaped with banishment. He fled to Darius III., who received him with distinction. But, having expressed his dissatisfaction with the preparations made by the king just before the battle of Issus (333), he was put to death.

CHARING CROSS, the locality about the west end of the Strand and the north end of Whitehall, on the south-east side of Trafalgar square, London. It falls within the bounds of the city of Westminster. Here Edward I. erected the last of the series of

¹According to some authorities, this is a second Charidemus, the first disappearing from history after being superseded by Chares in the Olynthian War.

crosses to the memory of his queen Eleanor (d. 1290). It stood near the present entrance to Charing Cross station, the terminus of the S.R. A fine modern cross has been erected within a few feet of the exact site. A popular derivation of the name connected it with Edward's "dear queen" (*chère reine*), and a village of Cherring or Charing grew up here later, but the true origin

TYPES OF CHARIOTS USED BY THREE NATIONS OF ANTIQUITY

1. Light Greek chariot equipped with four-spoked wheels (from a vase)
2. Roman chariot of the type driven in triumphal processions (from a medal of the Emperor Trajan)
3. Irish chariot used in battle. Closed in the back and open in front, this model is the reverse of those employed by the Greeks, Romans and Assyrians

of the name is not known; it is connected by some with that of a Saxon family, Cerring.

CHARIOT. In antiquity, a car used in battle, for the chase, in public processions and in games. The Greek chariot had two

wheels and was made to be drawn by two horses; if a third, or more commonly, two reserve horses were added, they were attached on each side of the main pair by a single trace fastened to the front of the chariot, as may be seen on two prize vases in the British Museum from the Panathenaic games at Athens. On the monuments there is no other sign of traces, from the want of which wheeling round must have been difficult. Immediately on the axle

A GREEK CHARIOT (REPRODUCED FROM THE MELOS VASE)

(ἄξων, *axis*), without springs of any kind, rested the basket or body (*δίφρος*) of the chariot, which consisted of a floor to stand on, and a semicircular guard round the front about half the height of the driver. It was entirely open at the back, so that the combatant might readily leap to the ground and up again as was necessary. There was no seat, and generally only room for the combatant and his charioteer to stand in. The pole (*ρῦμος*, *imo*) was probably attached to the middle of the axle, though it appears to spring from the front of the basket; at the end of the pole was the yoke (*ζυγόν*, *jugum*), which consisted of two small saddles fitting the necks of the horses, and fastened by broad bands round the chest. Besides this the harness of each horse consisted of a bridle and a pair of reins, mostly the same as in use now, made of leather and ornamented with studs of ivory or metal. The reins were passed through rings attached to the collar bands or yoke, and were long enough to be tied round the waist of the charioteer in case of his having to defend himself. The wheels and body of the chariot were usually of wood, strengthened in places with bronze or iron; the wheels had four to eight spokes and tires of bronze or iron. This description applies generally to the chariots of all the nations of antiquity.

Chariot Mountings.—The chariots of the Egyptians and Assyrians, with whom the bow was the principal arm of attack, were richly mounted with quivers full of arrows, while those of the Greeks, whose characteristic weapon was the spear, were plain except as regards mere decoration. Among the Persians, again, and more remarkably among the ancient Britons, there was a class of chariot having the wheels mounted with sharp, sickle-shaped blades, which cut to pieces whatever came in their way. This was probably an invention of the Persians; Cyrus the younger employed these chariots in large numbers. Among the Greeks and Romans, on the other hand, the chariot had passed out of use in war before historical times, and was retained only for

ASSYRIAN CHARIOT CARRYING BOWMEN

processions, without undergoing any alteration apparently, its form continuing to correspond with the description of Homer, though it was lighter in build, having to carry only the charioteer. On two Panathenaic prize vases in the British Museum are figures of racing *bigae*, in which, contrary to the description given above, the driver is seated with his feet resting on a board hanging down in front close to the legs of his horses. The *biga* itself consists of a seat resting on the axle, with a rail at each side to protect the driver from the wheels. The chariot was unsuited to the uneven soil of Greece and Italy, and it is not improbable that these nations had brought it with them as part of their original habits from their former seats in the East. The Jews used "iron" chariots apparently strengthened by metal.

Leaf in *Journal of Hellenic Studies*, v.; E. Buchholz, *Die homerischen Realien* (1871-85); W. Helbig, *Das homerische Epos aus den Denkmälern erläutert* (1884), and the article "Currus" in Daremberg and Saglio, *Dictionnaire des Antiquités*.

CHARISIUS, FLAVIUS SOSIPATER, Latin grammarian, flourished about the middle of the 4th century A.D. He was probably an African by birth, summoned to Constantinople to take the place of Euanthius, a learned commentator on Terence. The *Ars Grammatica* of Charisius, part of which is still extant, is valuable as containing excerpts from the earlier writers on grammar, who are in many cases mentioned by name—Q. Remmius Palaemon, C. Julius Romanus, Cominianus.

The best edition is by H. Keil, *Grammatici Latini*, i. (1857); see also article by G. Götz in Pauly-Wissowa's *Realencyklopädie*, iii. 2 (1899); Teuffel-Schwabe, *Hist. of Roman Literature* (Eng. trans.), § 419, 1. 2; Fröhde, in *Jahr. f. Philol.*, 18 suppl., 567-672 (1892). New edition by Barwick in Teubner series (1925).

CHARITON, of Aphrodisias, in Caria, the author of a Greek romance entitled *The Loves of Chaereas and Callirrhoe*, probably flourished in the 4th century A.D. The action of the story, which is to a certain extent historical, takes place during the time of the Peloponnesian War.

Editions by J. P. D'Orville (1783), G. A. Hirschig (1856), and R. Hercher (1859); there is an (anonymous) English trans. (1764); see also E. Rohde, *Der griechische Roman* (1900).

CHARITON, a city of southern Iowa, U.S.A., on the Chariton river, 53 m. S.E. of Des Moines; the county seat of Lucas county. It is on Federal highway 34, and is served by the Burlington and Rock Island railways. The population in 1930 Federal census was 5,365. Coal is mined in the vicinity, and the city has creameries, and broom and wagon factories. It was settled about 1850.

CHARITY. Few words have suffered greater changes either in meaning or in application than the word "Charity." It represents both a personal and a social endeavour to ameliorate the conditions which prevail in society. The endeavour should be founded on an intelligent examination of the factors that go to make up our social and industrial life and should be guided by a definite purpose. Most people have some sort of theory as to what is just and right in our relations with our fellowmen, but it is often so vague and undefined that its application is ineffective if not positively harmful. Most of the words used in Greek, Roman or Hebrew literature to signify good will are primarily words expressive of the affections, of the relations existing between parents and children or between husband and wife, such as ἀγάπη *amor*, *amicitia*. *Caritas* or charity on the other hand had a somewhat different meaning and referred rather to the relation of the individual to those outside his family; in the first instance *caritas* signified a high price, thus dearness. It was not dissimilar in meaning to the word χάρις which also had a commercial sense but signified as well gratitude, grace, kindness. In English ecclesiastical documents it was spelt *charitas*. In the authorized version of the New Testament ἀγάπη is translated charity, and it was used by St. Paul as a translation of the Hebrew word *hesed*, which in the same version of the Old Testament is translated "mercy"; e.g., "I desired mercy and not sacrifice." Almsgiving, *sedāquāh*, is translated by the word ἐλεημοσύνη in the Septuagint and in the Authorized Version by the word "righteousness"; it represents the deed which is done or the gift which is made under a sense of religious obligation.

In the early Christian period almsgiving has this meaning applied to a wide range of actions and contracts. The word *caritas*, charity or love, gradually assumes a higher meaning and represents an ideal social relation; e.g., in such phrases as "love of man." It has no necessary relation to relief or alms. It may mean a consideration shown for the welfare of others either individually or generally, although as a matter of fact charity has largely concerned itself with the help of the class usually called the poor, and with problems of distress. Relief need not, however, be an essential part of charity or charitable work; it is only one method by which those who have the means at their disposal can come to the assistance of others. The history of charity is a history of many social and religious theories, influences and endeavours that have left their mark alike upon the popular and cultivated thought of the present day. Inconsistencies of charitable effort may be accounted for by the evolution of society itself, by the growth of the educated social instinct. It is now

generally recognized that in addition to such suffering and want as befalls the evil-doer as a result of his ill deeds, there is a vast amount of suffering due to general social causes for which the sufferer is not responsible. Formerly it was the custom to say that the individual should alleviate this distress; to-day the feeling is general that society has a large amount of responsibility and is bound not only to alleviate it, but to remove its cause. Charity and in its broadest sense—philanthropy—is thus becoming an accepted part of social politics.

It will be readily understood that a history of charity would be a history of all the social and religious forces which have left their mark upon past generations in many countries. The growth of the habit of charity really represents a gradually educated social instinct. Every investigation into the conditions of social life has necessitated some sort of change in our view of charity, and legislation, as expressed in practical administration, has so removed the recipients of such charity from the sphere of what was formerly understood by charitable action that no charity can now be considered without reference to public relief. Charity has to be regarded in its bearing on every form of social relationship; e.g., thrift and national savings, parochial management, hospitals and medical relief, friendly visiting and almonership, distress resulting from unemployment, insurance against sickness and against unemployment, the utilization of endowments and their adaptation to new needs and emergencies. To a large extent the questions of widows and orphans, of vagrants and wayfarers, of the sick and the aged (in mediaeval times entirely a matter for the charity of the individual or of the institution) are now bound up with State law and public administration.

The Historical Growth of Charity.—The study of early communities is the study of the development of the family. It is only slowly that the larger social life of the tribe or clan has developed. In the earlier stages of civilization men were drawn together by unconscious physical causes which only very slowly and gradually, after thousands of years, became conscious ethical motives. At first even the child hardly belonged to the family; it belonged to the tribe. But when the social value of the bond between mother and father and child came to be recognized, the social value of the bond between members of the same clan became more obvious. As the parents' responsibility for their child increased, the interest of the State also developed, although even up to the 18th century it was undefined and uncertain.

The Greek Community.—If we take the *Odyssey* and *Hesiod* as representing the literature of the early Greeks we find the clan family and the phratry together constituting the self-contained unit of society with fairly clear views as to the necessity of helping the poor, of offering hospitality, of dealing with the wayfarer or vagrant. Everyone outside the phratry was a stranger; the man who had no brotherhood and was subject to no law, who had no hearth and no family was always suspect. He was in a difficult position because, although he wandered from place to place and received the alms of the community, he was a stranger, and in a country where hospitality was unknown and strangers were feared, he was liable to be attacked. Generally speaking, however, the wayfarer could find food and shelter and water for washing at the houses of the well-to-do, or he could share the hospitality of the peasants. The man who was a wayfarer and beggar almost by profession was not unknown. Begging was a recognized means of gaining a livelihood. Penelope, not recognizing Ulysses, said that if his tale were true she would give him better clothes and then he might beg his bread throughout the country-side. A system of almsgiving was recognized as a duty. The laws of social life as stated by *Hesiod* about 700 B.C. are comparatively simple. The groundwork of *Hesiod's* charity is neighbourly help, but this help is limited in character in so far as the community is concerned. A beggar is expected to do some sort of work in return for his food and shelter.

In the later Greek State, society consisted of citizens and slaves, the slaves enabling the citizens to have leisure for education, war and government. The slaves formed the larger part of the population and were permanently dependent upon members of the civic class, so that the only poverty was that of the poor

citizens, who were cared for in the first instance by the clan family. There was a growing sense of responsibility in regard to orphans, and guardians were appointed to care for them. Public policy and charity both dictated the policy of relieving the poverty of citizens and preserving citizenship. In Crete and Sparta the citizens were wholly supported out of the public resources. In Attica the citizens were aided in various ways; e.g., by legal enactments for release from debts, by emigration, a free supply of corn, poor relief for the infirm, and relief for the children of those fallen in war, not to speak of voluntary public service and gifts from individuals. Aristotle criticises very severely the distribution of public money to the poorer citizens and suggests the direction in which reform must be sought. He thinks that the habit of distributing the surplus revenues to the poor instead of holding back a certain proportion for a time of greater need is a mistake. He regards it as pouring water through a sieve. The problem for him is how to contrive that poverty should become temporary and not permanent, and his proposals are adequate public aid and voluntary charity. Public relief, he urges, should be given in larger amounts so as to help people to purchase small farms or start in business; the well-to-do should in the meantime subscribe to pay the poor for their attendance at the public assemblies. Aristotle evidently tried to show that unless the purpose of civil and social life was carefully considered and clearly realized by those who desire to improve its conditions, no change for the better could result from individual or associated action.

Charity in Roman Times.—The two words which most clearly define the Roman attitude towards what we call charity are *liberalitas* and *beneficium*. *Liberalitas*, according to Cicero, lays stress on the mood, the attitude of the *liber*, the free-born man who is independent and superior giving help to someone who is dependent and inferior. *Beneficium* on the other hand indicates the deed and its purpose. Cicero lays down three conditions which should be observed:—(1) Not to do harm to the person one would benefit; (2) not to exceed one's means; (3) to have regard to merit. The character of the person whom we would benefit should be considered and the deed or gift graded according to social relationship. In this connection there were three important factors in Roman life: the family, the *plebs* and slavery. The *plebs* who were the clients of the great patrician families were gradually impoverished and slavery increased *pari passu*. The impoverishment of the *plebs* led to the *annona civica* or free supply of corn to the poorer citizens, to the *sportula* or organized food supply for poor clients, and ultimately to the maintenance of children of citizens by voluntary and imperial bounty. The task of relief became hopeless under these conditions and the impoverished citizen degenerated into dependent, beggar, pauper and slave. The clan family in Rome was the dominant political factor. In its development it became unsocial, and the stronger clan families crushed the weaker. They obtained possession of the *ager publicus* which belonged to the State and in early days was distributed to citizens without property. More and more this land was acquired by the rich families, and although many attempts were made to compel them to surrender it, they were mostly unsuccessful, and other measures had to be taken to enable the poorest citizens to live. The right to relief was dependent on the right of citizenship; it was hereditary and passed from father to son. It was thus in the nature of a continuous endowed charity affecting not one family or group of families, but the whole population.

The Lex Claudia, passed in 58 B.C., which gave corn gratuitously to the *plebs urbana*, naturally attracted to Rome many people who wished to live without working and found it difficult to live elsewhere. The same system was introduced into Constantinople, Alexandria and Antioch. Later on, it became an imperative necessity to restrict the civic bounty to as few persons as possible. Those who received it, received it as a statutory right and no labour was required in return. The system was bad because it compelled those who worked hard to maintain the idlers, and it led to an increase of slavery since the man who could not live upon his grant had no alternative but to become

a slave. Thousands of citizens were unable to obtain land upon which they might have been able to gain a livelihood, and so were compelled to live in the towns, becoming gradually subjected to the conditions of a degrading pauperism. The *sportula*, to which reference has already been made, represented the charity of the patron to his clients and of the head of the clan family to those who attended at his house. It became a charity sufficiently important for State regulation; Nero limited the amount that might be paid in money and Domitian restored the custom of giving food.

Jewish and Christian Charity.—Throughout the Old Testament we find frequent references to the necessity for acts of charity, although almost always the kindred are entitled to the first consideration. Within the clan and tribe there are many poor oppressed by the rich. These rich are denounced frequently by the Prophets, and their denunciations form a valuable part of the national literature. In Job we find the family life developed side by side with the life of charity; the relief of the widow, the fatherless and the stranger are all enjoined, and this is the classification of dependents in the Christian Church. In the "*Didache*" (a Jewish Christian writing of about A.D. 90-120) the great commandments are adapted from St. Matthew's gospel, first "Thou shalt love God who made thee," second "thy neighbour as thyself"; and "all things whatsoever thou wouldst not have done unto thee, neither do thou to another." It is not necessary to dwell upon the sources of relief among the Jews but they were not systematized until at last permanent provision almost equal to a poor rate was made for the relief of the poor. In the early Christian Church this became free will offerings, first fruits and voluntary tithes brought to the bishop and used for the poor. The Jews in pre-Christian and Talmudic times supported the stranger or wayfarer by the distribution of food. The strangers were lodged in private houses and there were inns provided at which no money was taken. Subsequently special societies were formed for the entertainment of the resident poor and of strangers. These conditions prevailed in the Christian Church also. The Xenodocheion was the first form of Christian hospital both for strangers and for members of the Christian churches, and there are precedents both Jewish and Greek. In the Christian community the endowed charity comes into existence in the 4th century, but not among the Jews until the 13th century. Up to that time the charities of the synagogue were regarded as sufficient. St. Paul in his Epistle to the Corinthians represents the views of the early Christian Church on charity, and St. Francis at a much later date revives the same idea, though for hundreds of years afterwards little advance was made. In many respects there was retrogression in so far as the conception and purpose of charity is concerned. St. Paul considers charity in relation to a community of fellow-believers. He speaks as an outsider in relation to the State although he is technically a citizen, but social life and its needs are not uppermost in his thoughts because he is intent on creating a spiritual association. Paul wished to create a body of men and women linked together by love outside the normal life of the community. This was a new form of religious organization. According to the Christian maxim rightly understood "loving one's neighbour as oneself" set the standard of charity. The nobler the self, the completer the charity, and the charity of the best men, men who love and understand their neighbours best, having regard to their chief good, is the best and most effective charity. In later Christian thought the whole idea degenerated. The aid of the poor was not considered as an end in itself, an act of brotherly love, but as a means by which the almsgiver "makes God his debtor." Charity has nothing whatever to do with rewards and punishments, and yet St. Chrysostom says "if there were no poor, the greater part of your sins would not be removed; they are the healers of your wounds." Alms are thus the medicine of sin and this same thought is found in the penitential system. Almsgiving thus becomes detached from charity on the one side and social good on the other. It is considered that alms are paid to the credit of the giver and realized by him in the next world, a false view which has been handed down through

successive generations. The general idea of almsgiving for some hundreds of years has nothing whatever to do with social progress. It has no width of vision to understand the needs of those who are suffering from sickness or distress and no moral energy to effect their permanent relief. Those who hold this view of charity believe that "the poor will never cease from out the land," and indeed that it would be a bad thing if they did so cease because it would hinder their own spiritual progress.

The sub-apostolic church was congregational, the centre of a system of voluntary and personal relief connected with the congregational meals, the *ἀγάπαι* and under the supervision of a single officer or bishop. Out of this was developed a system of relief controlled by a bishop assisted by deacons or presbyters, while the *ἀγάπαι* consisting of offerings laid before the altar still remained. Finally these offerings became a dole of food or poor people's meal. The church fund during the second period of Christianity (c. A.D. 150–200) was a friendly fund supported by voluntary gifts used to succour and bury the poor, to help destitute and orphan children, old household slaves and those who suffered for the faith. With the growth of the parochial system parishes were placed under the charge of priests and deacons. It was the duty of the deacons to care for the poor, widows, orphans, wards and old people of their several districts. They drew up lists of those who received regular relief, and in Rome, as this system developed, the sick and infirm were superintended by persons appointed to inspect every street and a distribution was made in kind on the first day of every month. Before St. Gregory sat down to his meal a portion was separated and sent out to the hungry at his door. The Roman *plebs* had thus become the *pauperes Christi*. At the same time there was a system of relief independent of the churches, and the *hospitium* was now part of a common organization of relief very much on the lines of poor relief in the middle ages when the churches on the one hand and the public authorities on the other relieved the poor in times of scarcity and distress.

The Endowment of Charity.—The endowed charity grew up during the Byzantine period and officers appear like the almoner and the steward to superintend and distribute the alms and manage the property of the institution. St. Basil at Caesarea founded quite a colony of institutions, guest houses, poor houses, orphanages and houses for infant children. Bequests to the church were frequent for such institutions and in course of time the clergy became the owners of large properties and the administrators of endowed charities which with modifications continued throughout the middle ages and exists even to this day in various forms of parochial relief. Monasticism failed to solve the problem of the relief of the poor, although the institutions set up by the monasteries became extremely powerful and in some cases wealthy. The monasteries were out of sympathy with the charities of the parish, and as they were a class apart from other charities, they were separately administered. The belief in poverty as a fixed condition, only to be alleviated and never removed, was fundamental with monasticism. At the close of the period which ends with St. Gregory and the founding of the mediaeval church, economic and social conditions were adverse, and charity is reflected in the attempts to alleviate the suffering and the misery of those times. The public service was corrupt, the rich evaded taxation, the poor were oppressed, well-to-do society seemed to be decaying. Hospitals increased, but medicine was unprogressive. There were years of famine and of pestilence with which the authorities were unable to cope and there were constant wars. This will account for the large number of the poor who became a charge on the Church. The Church helped widows, orphans and the sick, it ransomed slaves, although it did not abolish slavery. The serf who was attached to the soil took the place of the slave, and almsgiving took the place of the *annona civica* and the *sportula*. Economic conditions were unfavourable to the independence and self-support of society as a whole, and this state of things continued for some hundreds of years.

We have referred to the two methods of relief which have usually been prominent, relief administered locally, chiefly to residents in their own homes, and relief administered in an

institution. At the time of Charlemagne (742–814) the system of relief was parochial, consisting principally of assistance in the home. After that time, except probably in England, the institutional method appears to have predominated and the monastery or hospital in one form or another gradually encroached on the parish. St. Francis differed from the teachers of his own period since he brought reality once more to bear upon the question of social duty. For him the poor were once again the *pauperes Christi*; to follow Christ was to live among the people the life of the poor man. The disciple was to work with his hands, to receive no money, to earn the actual necessities of life, though what he could not earn he might beg. To work for food and lodging was a right so long as he was bringing a better life into the world, and anything in excess of his normal requirements must be given to the poor. He would possess no property, no buildings or endowments, and in effect the movement was a lay movement, the force of which consisted in its simplicity and directness. It was inspired by a social endeavour and entirely transformed the idea of charity.

Five Centuries of Charity in England.—If we turn to England in the 14th and 15th centuries we find the population almost stationary, the towns comparatively small and London almost the only one with a population of 40,000 or 50,000. There was much poverty even though the 15th century was supposed to be the golden age of the labourer. Side by side with the charitable relief system of the parish was the self-supporting system of the manor, the manor being an economic unit, the estate of a lord on which there were associated the lord with his desmesne, tenants free of service, and villeins and others who were tenants by service. But in addition to the parish as the centre of relief there were the monasteries and the hospitals. The almonry of the monastery was near the church of the monastery and the almoner distributed his doles to travellers, palmers, chaplains and mendicants. It was his duty to visit and relieve the old, infirm, lame and blind, who were confined to their beds, and the remnants of meals and the old clothes of the monks were given to the almoner for distribution. The monasteries often established hospitals which served also as schools both for the gentry and for the poor. The monasteries began seriously to decline in the 15th century and their resources were greatly crippled. They had no common controlling organization and were just miscellaneous centres of relief. They stood outside the parish and rather hampered than helped its development. The hospitals were at first established for various purposes—for the poor, the infirm, the lame and blind, and for lepers outside the towns. The hospital in its modern sense was only very slowly created, St. Bartholomew's being founded in 1123 for the entertainment of poor diseased persons until they got well and for the maintenance until the age of seven of all children whose mothers died in the house. Amongst the mendicant orders the Franciscans attended the sick and poor in the slums of the towns with great devotion.

The system of relief had thus become a system of charitable endowments in connection with churches, monasteries and hospitals. This must be contrasted with the modern method of voluntary associations or rate-supported institutions. As the towns grew in size, guilds sprang up and charities were founded for members of the guilds. Rich men left their estates to their guilds to maintain decayed members in hospitals and almshouses, to educate their children, to give dowries to their daughters and to assist their widows. The boroughs also established charities, gave outdoor relief to the registered poor, and took over the duty of caring for the orphans; and thus towards the close of the middle ages the towns were gradually usurping what had formerly been the province of the Church. By the Statutes of Labourers, beginning in 1531, an endeavour was made to enforce a settled wage and restrain migration from the country to the town. An attempt was also made to suppress mendicity, the idea being to keep the people in some settled industry of the crafts or of agriculture or to force them back into such occupation if they had left it. The beggar was punished as unsocial. It is his fault if he belongs to no one; he must be made some-

body's dependent and kept so, and if no one will keep him his mendicity must be organized. Out of the failure to organize mendicity springs the poor law, and for at least two centuries the idea of statutory wage control and statutory poor relief seems to have been firmly fixed in the English legislative mind. In Henry VIII.'s time the system of relief from endowed charities, supported chiefly by rents from landed property, began to disappear and since the monasteries and religious houses were dissolved, little was left but relief in the shape of alms given in an isolated and unmethodical way. The property of the hospitals and the guilds was in many cases confiscated and a new organization of charitable relief had to be created. The poor could only be relieved as it seemed by a compulsory rate, and the administration of statutory relief naturally devolved on the central government. A poor law was enacted which still remains on the statute-book, although it has been modified by innumerable Local Government Board orders. The principle of poor law relief from a compulsory rate having been adopted, it was enacted (1572-73) that the aged and infirm should be cared for by the overseers of the poor, a new authority, and in 1601 the duplicate acts were passed, viz., that for the relief of the poor (43 Eliz. 2) and that for the furtherance and protection of endowed charities. Thus the poor were given the condition of a legally recognized class endowed with a claim for relief.

Poor Relief Act, 1662.—The Poor Relief Act of 1662 brought in the law of settlement which made the English labourer a settled but landless serf, supported by a fixed wage and a State bounty. The poor law was philanthropic in its origin, but philanthropy rapidly disappeared. Its object was to relieve the poor by home industries, to apprentice children, and to provide necessary relief for the poor unable to work. The economic fallacy of home industries founded on rate-supplied capital soon declared itself, and when workhouses were established in the 18th century, the same industrial fallacy recurred. The farmer paid the labourer as small a wage as possible and left it to the parish to provide whatever he might require in addition during his working life and his old age. The policy adopted by Queen Elizabeth for the relief of the poor included a scheme for the reorganization of voluntary charity as well as plans for the extension of rate-aided relief. Accordingly in the poor law it was arranged that the overseers (the new civic authority) and the church wardens (the old parochial or charitable authority) should act in conjunction and should raise the necessary means by taxation of every inhabitant. What the church wardens were unable to obtain from endowments they and the overseers could secure by taxation. Towards the end of the 18th century, when the administration of poor relief fell into confusion, many charities were lost or were in danger of being lost and many were mismanaged. In 1786 and 1788 a committee of the House of Commons reported on the subject. In 1818, chiefly through the instrumentality of Lord Brougham, a commission of enquiry on educational charities was appointed, and in 1819 another commission was set up to investigate charities for the poor in England and Wales. These inquiries were continued until 1838 when a select committee of the House of Commons made a strong report urging the establishment of a permanent and independent board of inquiry to compel the production of accounts, to secure the safe custody of charity property and to adapt it to new uses.

Charity Commissioners, 1853.—A commission followed in 1849, and eventually in 1853 the first Charitable Trust Act was passed under which the charity commissioners of England and Wales were appointed. Where charities have been remodelled under schemes of the charity commissioners, there are now appointed, besides trustees elected by corporations, *ex officio* trustees who represent some office or institution of importance in connection with charities. The charity commissioners have power where the objects for which a charity was founded are obsolete or the directions of the testator obscure to apply the income of the charity to other purposes as far as possible in accordance with the charitable intention of the founder. In the remodelling of charities for the general benefit of the poor some one or more

of 13 objects are usually included, such as a medical charity, provident club, friendly society, assistance to nurses, etc. Homes for abandoned children were established during the 17th century both in France and in England, and grants from parliament supported the movement. The Foundling Hospital was established in 1739. As a rule these foundling homes were badly managed and the infant death rate was enormous. General reforms were made, especially through the instrumentality of Jonas Hanway, to check infant mortality, and metropolitan parishes were required to provide for their children outside of London. Penitentiaries were established in 1758 and lock hospitals and lying-in hospitals in 1749-52. In Queen Anne's reign there was a new education movement, a charity school to teach poor children the alphabet and the principles of religion. This was followed by a Sunday school movement in 1780, and about the same time (1788) by the school of industry to employ children and teach them to be industrious. In 1844 the Ragged School Union was established and continued to do educational work until the Education Act of 1870. Industrial and reformatory schools were established to prevent crime and reform child criminals in 1854-56. The orphanage movement continued to grow and, supported by voluntary gifts, has greatly increased in size. After the Civil War the old hospital foundations of St. Bartholomew and St. Thomas became endowed charities, partly supported by voluntary contributions, and in the case of Christ's Hospital the voting system made its appearance.

Towards the end of the 18th century the dispensary movement was developed, culminating in the provident dispensary which made it possible for patients by means of small contributions in time of health to provide for sickness without having to make large payments. Hospital funds have also been established for making grants to various hospitals both in London and elsewhere. The magnitude of this accumulating provision of charitable relief in connection with churches and voluntary societies cannot well be estimated, but undoubtedly it has reached a huge total. Dr. Munsterberg once said "there is no country in the world in which so large an amount is given in charity as in England and no country where less good is done with it."

It is extremely difficult to estimate either the income or the expenditure of charitable societies in Great Britain, but an estimate has been made in connection with metropolitan charities, although these are often provincial as well and receive contributions from all parts of the country and even from abroad. It is estimated that for the year 1924-25 the turnover of the institutions for which information is available was £14,065,307. The voluntary contributions amounted to £6,192,883. The receipts from interest on invested funds and rents of property were £2,653,599. In addition a sum of £4,115,231 was due to payments by or for beneficiaries, an amount which must vary considerably from time to time. Legacies represented £1,387,166. The remaining sum was due to trading and industrial operations and miscellaneous receipts. The expenditure on these institutions amounted to £11,538,717 upon maintenance, out of which £1,234,739 was the charge for management or about 10% upon the gross expenditure.

Charity Organization Society.—The feeling that many charitable efforts were wasted and did more harm than good led to the establishment in the early 19th century of anti-mendicity societies. In 1869 the movement for the organization of charity led to the formation of the Charity Organization Society, originally the Society for Organizing Charitable Relief and Suppressing Mendicity. The movement spread to America and the British Colonies, the first American Charitable Organization Society being formed in 1877. All these societies resolutely opposed indiscriminate and casual alms-giving, and organized a relief system based on careful personal inquiry. The charity organization movement, while it has never succeeded in winning the complete confidence of the working classes, has nevertheless made it clear to most people that ill-considered philanthropy may do much more harm than good and that personal interest and sympathy may be the decisive factor in any attempt to help the individual or family in distress. Certainly the Charity Organization Society

has never thought it right to accept the poor as a permanent class, and whatever view may be taken of its methods, the idea underlying its efforts has always been to avoid the creation of a dependent class and to raise the poor above the conditions of serfdom.

As a result of the continued interest taken in the administration of charity, the Association for Befriending Young Servants was formed as well as workhouse aid committees to prevent a relapse into pauperism on the part of those who as children or young women receive relief from the poor law. For a time at least a restricted out-door relief policy was adopted and such a policy would still be the aim of organized charity, but for many reasons it has broken down, and it is impossible to assert that in times of serious unemployment restricted out-door relief can be maintained. The well known Elberfeld system (*q.v.*) on the Continent had a considerable influence upon thought both in England and America. It was a system of municipal relief administered by unpaid almoners, each dealing with a few cases, and seems to have been attended with great success wherever it has been carefully practised. Its success, however, depends upon the services of a sufficient number of unselfish almoners who have tact and ability and a desire to serve the best interest not only of the individual but of the community.

The work of the Charity Organization Society followed the lines laid down by the late C. S. Loch. The methods are briefly as follow: the central committee is composed of representatives of relief societies, religious agencies, endowed societies and representatives of local authorities, such as poor law guardians; full inquiry is made into each case and all the particulars are registered so as to prevent the possibility of overlapping; when help is given it is obtained so far as possible from relatives, employers and various charities. A system of training has been established for those who are engaged in this work, and Charity Organization Society workers when trained often become poor law guardians, secretaries of charitable societies and district visitors.

The investigations of Charles Booth, Seebohm Rowntree and others, the influence of men like Canon Barnett and Arnold Toynbee, and the university settlements generally, have somewhat changed the method of charity, which has now assumed the form of a new devotion to the duties of citizenship. Perhaps this was hardly possible until the scope of legislation had been more accurately determined and until statistics and investigation had made it clear how far charity itself failed to remove the causes of poverty. But the view of those who contend that so far as possible help should only be given after careful inquiry by organized charity is still widely held.

The Charity Organization Society is perhaps justified in contending that the poor law relief tends to increase. The average number of persons in receipt of domiciliary relief returned as being ordinarily employed, with their dependents, was for the year 1926-27 1,217,083, or 313 per 10,000 of the population and for 1925-26 478,454 or 123 per 10,000 of the population. This immense discrepancy was due of course to certain dominant features in 1926-27; viz., the increase of pauperism resulting from a general stoppage in the coal mining industry and from the general strike. Roughly speaking, we may say that 1,000,000 British people are as a rule in receipt of domiciliary relief other than medical relief, and of these nearly half would be insured persons and their dependents. The poor law is very much what the guardians chose to make it. It may become an influence definitely antagonistic to the proper development of family life, or even a method of pauperizing the working classes.

Certain boards of guardians have been removed from their position by the ministry of health, and in each case a commission of three guardians has been appointed to take the place of the board. The boards were accused of making illegal payments and of reckless extravagance. It is not necessary in this article to enter into details with regard to these boards of guardians, but apart altogether from the controversial question of the abolition of the poor law and the distribution of the duties of the guardians amongst other local authorities, it is obvious that some administrative changes are required. In large industrial districts in

which there is a considerable amount of unemployment and poverty, there may be thousands of voters who are unwilling to vote for any guardians except such as promise to give them relief on the highest possible scale. This is an impossible state of affairs which will have to be remedied; otherwise no honourable person will come forward as a candidate for the board of guardians in places where they are subject to extreme pressure on the part of electors who are themselves to benefit as a result of the election by securing relief out of the rates. Even where the elector is not unemployed or in distress at the time of the election he may have in view the possibility of requiring assistance in the immediate future, and if he allows unworthy motives to influence his action he is in exactly the same position as the elector who requires immediate assistance and votes only for those candidates who are known to be generous with the rate-payers' money. In such cases, relief out of the rates becomes a public charity administered in a spirit which is demoralizing both to the giver and to the receiver. Some solution must be found of this difficult problem, otherwise the Ministry of Health will be compelled to deal with other boards of guardians as they have dealt with certain local authorities in the past. It would of course be impossible to disqualify the elector who has not received assistance but fears he may require it in the near future; but it seems just that votes should be withheld from those electors who are personally interested in the return of certain guardians because they are known to give relief with a lavish hand. The other alternative would be to appoint commissioners for the administration of relief who would serve much the same purpose as the commissioners appointed in certain American cities where corruption has been rampant. It has been argued that as each elector contributes to the rates he has the right to vote for any person he thinks fit; but as a matter of fact the electors to whom reference has been made do not contribute to the rates even in the shape of rent, for the rent itself is defrayed out of the rates.

The attitude of the Charity Organization Society towards much social legislation is that while it aims at improving social conditions, it weakens society itself. Charity, it is argued, has never objected to prison reform, industrial schools, child protection, housing and food reform. It has been a friendly ally in many reforms that affect industry very closely; e.g., in the introduction of the Factory Acts, but it has never aimed at recasting society itself on a new economic plan. The organizers of charity object that British legislation is gradually creating a new industrial society in which the wage is regulated and everyone subsidized. They argue that the State maintenance of school children, old age pensions, and State provision for the unemployed all lead to a final stage in which everyone will be supported by society or be dependent on it industrially. In their opinion this would exclude motives for energy and endeavour and would also exclude the ethical element from life. Organized charity believes that such quasi-socialistic action will sooner or later mean a fatal want of initiative in the class helped. From a wider point of view, it must be remembered that the mistakes made by the nation in the past have been largely due to ignorance. It is only recently that the possibility of more thorough remedies has been grasped and that social responsibility has been recognized for evils which are avoidable. Statistics have shown not only the extent of social distress but the method of remedy in many cases, and social philosophy now teaches that poverty and disease are not always the result of misdemeanour on the part of the sufferer. There can be no doubt that a vast amount of suffering is due to general social causes; for such distress society is responsible and is bound to alleviate and remove it.

State and Private Action.—It is difficult to say what are the limits of public and private work respectively in the sphere of relieving distress, but again and again the State has been compelled to take over tasks for which private philanthropy found itself unfitted. In a British white paper published in Nov. 1927, dealing with public social services, a financial statement is given regarding the cost of such services as national insurance, old age pensions, unemployment, war pensions, educa-

tion, public health acts, housing of the working classes, lunacy, inebriates, mental deficiency. It is there shown that for 1926, the latest available year for statistics, the cost of these services in England and Wales was out of local rates £74,987,149, and out of Parliamentary votes and grants £155,747,237. The amount contributed from other sources; *i.e.*, revenue from endowments, voluntary contributions both of employers and employed, etc. was £83,239,745. This large sum of over £80,000,000 in England and Wales and over £10,000,000 in Scotland represents money contributed to objects which formerly would have been regarded as in the sphere of private charity. In this sum is included £6,226,433 contributed towards the cost of education in England and Wales, chiefly from endowments, and £1,009,325 in Scotland from similar sources.

There is perhaps another reason for the gradual encroachment of the State on the province of charity; whereas charity formerly confined itself to efforts for alleviation, to-day prevention is regarded as primary. Indeed, the whole theory of government has changed, for we no longer aim at merely holding the scales between the different classes of the community. The idea of government is to consider also how the value of life may be enhanced. We remember with gratitude that charity stepped in to help the poor when the poor seemed to have no other helper, but we must remember at the same time that such assistance was often very inadequate. Whether we consider the lunatic asylums or the prisons or the many other fields of charitable labour that were at one time in the hands of the philanthropists, we must admit that at last it became necessary for the State to step in and to do for the poor of all grades what charity had been unable to do for them. And always a deep debt of gratitude remains to the many great philanthropists of this transition period, such as Wilberforce, Howard, Owen, Allen and Mrs. Fry.

The Charity Organization Society itself sees that the State is slowly encroaching upon the sphere of charity, but it is right in its assertion that in this transition stage organization is necessary and that as a condition precedent to all organization there must be in each town or township some local centre of association for information and common help. This local centre is sometimes the Charity Organization Society itself, sometimes a guild of help, and in 40 or 50 towns a branch of the National Council of Social Service. The method is that of associated help combined with personal work, and is adopted, with innumerable varieties, in America, Germany and elsewhere. In the United States relief is now often given out of a common pool called the Community Chest and every endeavour is made to prevent overlapping.

Widows, Orphans and Old Age Pensions Act.—Recent legislation in Great Britain has shown how help that was formerly given by a committee is now rendered by the State through the medium of the local authority; in Jan. 1928 the Widows, Orphans and Old Age Pensions Act came into operation by which a large class of individuals formerly assisted by private charity was absorbed in the scheme of social insurance. This comprises insurance against old age as a supplement to the Old Age Pensions Act of 1890, insurance against sickness, unemployment insurance, help for widows and orphans under certain definite conditions, and other benefits. The original Old Age Pensions Act was non-contributory and was therefore opposed by the Charity Organization Society, but the subsequent Acts are rendered less dangerous in their view by the contributory principle.

Finally, we may attribute much recent British legislation to a change which has come over public opinion as a result of investigations into the causes and extent of poverty. Sociologists have shown us that, whatever may be our view of the remedies, the causes are not purely individual. Their studies have created a predisposition towards concerted social action. Charity was a pre-scientific attempt to do something which needed to be done, but which could only succeed in slightly ameliorating, and never in curing, the evil itself. The accumulated weight of social knowledge which has been acquired has changed our view of the function of charity. Statistical inquiry has discovered a much

more intricate social interdependence than has been suspected. This interdependence is progressive. The more complex our society, the more interdependent we are, and the greater becomes the need for recognizing that society is something more than an aggregate of units. Statistics have helped enormously in the study of sociology because they bring together the facts calculated to illustrate the condition and prospects of society. The sociology of to-day gives us a new reading of human nature and a deeper conception of our social life. The State has intervened and has annexed a large part of what was formerly the sphere of charity, as in the cases of elementary education and the health of the child.

In Great Britain the State has also divided its responsibility for disease and sickness with the local authorities, friendly societies and approved societies. This is also noticeable in the case of hospitals; some are controlled by the municipality while others are supported by voluntary contributions. Sometimes the State co-operates, as with the Prisoners Aid Society, and occasionally it attempts to co-ordinate and supervise, as with the inebriate homes, etc. Both the State and the local authority are active, but there is still plenty of room for voluntary service, not only in connection with education but in prisons and reformatories, infirmaries and hospitals. With regard to the latter, it is interesting to note that the income of King Edward's Hospital Fund for the year 1926 was £285,749 and that the total receipts of all the London voluntary hospitals in that year was £3,887,000. The income of the Hospital Saturday (General) Fund amounted in 1926 to £79,192. There are still a few cases in which charitable societies carry out work which would seem to be the responsibility of the State; *e.g.*, the Society for the Prevention of Cruelty to Children, which has a royal charter and obtains from the public by subscriptions the necessary funds for maintaining its work.

All charitable work has now to take account of these new factors and this fresh view of social responsibility. It used to be assumed that our social and industrial system was satisfactory on the whole, and that it was the individual who was solely to blame. But men fail in life from all kinds of misfortunes over which they have no control, and in all such cases of injustice and hardship the most important thing is to aim at a change of circumstances. Everyone admits that the standard of life has been raised from century to century, and that the working classes are infinitely better off than in the middle ages, but who would contend that this is due to the administration of charity? The improvement is due to economic causes and the growth of an educated public opinion. What remains to be done is something more than the effort of organized charity, valuable as it is in the relief of distress. Constructive philanthropy must unite with all the forces that make for social betterment, including the work of local authorities and of parliament. The philanthropist will always bear in mind that a considerable proportion of the people have inherited conditions which, although an improvement upon the environment of their forefathers, are nevertheless a severe handicap to social advancement. He will not therefore be alarmed or surprised if he sees that, owing to the irresistible pressure of events, a large part of the work performed by charitable societies in the past is gradually passing into other hands. (*See POOR LAW; CHARITY COMMISSIONERS; CASUAL WARD; OLD AGE PENSIONS; UNEMPLOYMENT INSURANCE; ELBERFELD SYSTEM.*)

CHARITY COMMISSIONERS FOR ENGLAND AND WALES. Between the years 1818 and 1850 prolonged investigations were made into the condition of British charities by a Parliamentary Commission of Enquiry (1818-37), by a select Committee of the House of Commons (1835), and a Royal Commission appointed in 1849. The reports made by these bodies recommended the appointment of a permanent board to which should be entrusted wide powers to improve the administration of all charities, to safeguard their funds and secure their proper investment, and to give ready and effectual expression of the doctrine of *cy pres*, as administered by Courts of Equity, by framing schemes for adapting the administration of charities to the altered circumstances, whether of the charity property, of the locality, or of society generally.

By the Charitable Trusts acts, 1853-1925, the Charity Com-

mission was set up to carry out these important duties. In addition to their powers under the Charitable Trusts acts, the Charity Commissioners exercise jurisdiction in relation to charities under numerous acts of Parliament, including the Local Government act, 1894, the Mortmain and Charitable Uses acts, 1888-92, the Commons act, 1899, the War Charities act, 1916, and the Blind Persons act, 1920. The jurisdiction of the Commissioners (subject to certain exemptions) extends to all endowed Charities in England and Wales, other than Educational Charities (which are subject to the jurisdiction of the Board of Education).

The exemptions from the jurisdiction of the Commissioners are universities, cathedrals, registered places of worship, Queen Anne's Bounty, the British Museum, friendly societies and savings banks, religious or charitable institutions maintained by voluntary contributions, and mixed charities (*i.e.*, charities partly voluntary and partly endowed) so far as regards the income which is derived from voluntary contributions.

The Charitable Trusts acts make provision for safeguarding charitable endowments by the constitution of:—

(a) The Official Trustee of Charity Lands. A Corporation Sole for taking and holding Charity Lands which may be vested in him by any Court of competent jurisdiction or by an order of the Charity Commissioners.

(b) The Official Trustees of Charitable Funds, incorporated for holding stocks, shares, securities and monies.

These are bare trustees only, and have no power to interfere in the administration of the lands or securities vested in them, or in the management of any charity.

The greater part of charity land is now vested in the Official Trustee of Charity Lands, whilst the total sum of stocks and investments held by the Official Trustees of Charitable Funds amounts to nearly £70,000,000 and is increasing annually.

CHARIVARI, a French term of uncertain origin, but probably onomatopoeic, for a mock serenade, "rough music," made by beating on kettles, fire-irons, tea-trays or tin pans. The charivari was anciently in France a regular wedding custom, all bridal couples being thus serenaded. Later it was reserved for ill-assorted and unpopular marriages, and as a mockery for all who were unpopular. At the beginning of the 17th century, wedding charivaris were forbidden by the Council of Tours, but the custom still lingers in rural districts. The French of Louisiana and Canada introduced the charivari into America, where it became known under the corrupted name of "shivaree."

CHARKHARI, an Indian state in the Bundelkhand agency of Central India. Area, 880 sq.m.; pop. (1921) 123,405. It is surrounded on all sides by other states of Central India, except near Charkhari town, where it meets the United Provinces. It was founded by Bijai Bahadur, a *sanad* being granted him in 1804 and another in 1811. The chief, whose title is maharaja, is a Rajput of the Bundela clan, descended from Chhatar Sal, the champion of the independence of Bundelkhand in the 18th century. In 1857 Raja Ratan Singh received a hereditary salute of 11 guns, a *khilat* and a perpetual *jagir* of £1300 a year in recognition of his services during the Mutiny. The town of Charkhari (locally *Maharajnagar*) is 40 m. W. of Banda; pop. (1921) 9,582.

CHARLATAN, originally one who "patters" to a crowd to sell his wares (Ital. *ciarlatano*, from *ciarlare*, to chatter), like a "cheap-jack" or "quack" doctor—"quack" being similarly derived from the noise made by a duck; so an impostor, who pretends to have some special skill or knowledge.

CHARLEMAGNE LEGENDS. Innumerable legends soon gathered round the memory of the great emperor. He was represented as a warrior performing superhuman feats, as a ruler dispensing perfect justice, and even as a martyr suffering for the faith. It was confidently believed towards the close of the 10th century that he had made a pilgrimage to Jerusalem; and, as in the case of many other great rulers, it was reported that he was only sleeping to awake in the hour of his country's need. The legendary Charlemagne and his warriors were endowed with the great deeds of earlier kings and heroes of the Frankish kingdom, for the romancers were not troubled by considerations of chronology. National traditions extending over centuries were grouped round

Charlemagne, his father Pippin, and his son Louis. The history of Charles Martel especially was absorbed in the Charlemagne legend. But if Charles's name was associated with the heroism of his predecessors he was credited with equal readiness with the weaknesses of his successors. In the histories of the wars with his vassals he is often little more than a tyrannical dotard, who is made to submit to gross insult. This picture of affairs is drawn from later times, and the sympathies of the poet are generally with the rebels against the monarchy.

Charlemagne's wars in Italy, Spain and Saxony formed part of the common epic material, and there are references to his wars against the Slavs; but especially he remained in the popular mind as the great champion of Christianity against the creed of Mohammed. In 1164 Charles was canonized; yet this gave him no real claim to sainthood, but his festival was observed in some places until comparatively recent times. Charlemagne was endowed with the good and bad qualities of the epic king, and as in the case of Agamemnon and Arthur, his exploits paled beside those of his chief warriors. These were not originally known as the peers famous in later Carolingian romance. The peers numbered 12 most probably by analogy with the 12 Apostles. The lists of them are very various, but all include the names of Roland and Oliver. The chief heroes who fought Charlemagne's battles were Roland; Ganelon, afterwards the traitor; Turpin, the fighting archbishop of Reims; Duke Naimes of Bavaria, the wise counsellor who is always on the side of justice; Ogier the Dane, the hero of a whole series of romances; and Guillaume of Toulouse, the defender of Narbonne.

The defeat of Roncevalles, which so deeply impressed the popular mind, has not a corresponding importance in real history. But it chanced to find as its exponent a poet whose genius established in the *Chanson de Roland* (*see* ROLAND, LEGEND OF) a model for his successors, and definitely fixed the type of later heroic poems. The other early *chansons* to which reference is made in *Roland* are *Aspremont*, *Enfances Ogier*, *Guiteclin*, *Balan*, relating to Charlemagne's wars in Italy and Saxony. *Basin* or *Carl et Elégast* (preserved in Dutch and Icelandic), the *Pèlerinage de Charlemagne* and *Le Couronnement Looys* also belong to the heroic period. The purely fictitious and romantic tales added to the personal history of Charlemagne and his warriors in the 13th century are inferior in manner, and belong to the decadence of romance. The old tales, very much distorted in the 15th century prose versions, were to undergo still further degradation in 18th century compilations.

According to *Berte aus grans piés*, in the 13th century *remaniement* of the Brabantine *trouvère* Adenet le Roi, Charlemagne was the son of Pippin and of Berte, the daughter of Flore and Blanchefleur, king and queen of Hungary. *Mainet* (12th century) and the kindred poems in German and Italian relate the *enfances* (youthful exploits) of Charlemagne. He delivered Rome from the besieging Saracens, and returned to France in triumph. But his wife Galiene, daughter of Galafre, whom he had converted to the Christian faith, died on her way to rejoin him. Charlemagne then made an expedition to Italy (*Enfances Ogier* in the Venetian *Charlemagne*, and the first part of the *Chevalerie Ogier de Danemarche* by Raimbert of Paris, 12th century) to raise the siege of Rome, which was besieged by the Saracen emir Corsuble. *Aspremont* (12th century) describes a fictitious campaign against the Saracen King Agolant in Calabria, and is chiefly devoted to the *enfances* of Roland. The wars of Charlemagne with his vassals are described in *Girart de Roussillon*, *Renaut de Montauban*, *Huon de Bordeaux*, and in the latter part of the *Chevalerie Ogier*, which belong properly to the cycle connected with Doon of Mayence.

The legend of the pilgrimage of Charlemagne to the Holy Sepulchre probably originated in a desire to authenticate the relics in the abbey of Saint Denis, supposed to have been brought to Aix by Charlemagne, and is preserved in a 12th-century romance, *Le Pèlerinage de Charlemagne*. The legend of the conquest of Armoria is preserved in *Aiquin* (12th century). *La destruction de Rome* is a 13th-century version of the older *chanson* of the emir Balan, who collected an army in Spain and sailed to Rome. The defenders were overpowered and the city destroyed before the

advent of Charlemagne, who, however, avenged the disaster by a great battle in Spain. The romance of *Fierabras* (13th century) was one of the most popular in the 15th century, and by later additions came to have pretensions to be a complete history of Charlemagne. *Otinél* (13th century) is also pure fiction. *L'Entrée en Espagne*, preserved in a 14th-century Italian compilation, relates the beginning of the Spanish War, the siege of Pampeluna, and the legendary combat of Roland with Ferragus. Charlemagne's march on Saragossa, and the capture of Huesca, Barcelona and Gironne, gave rise to *La Prise de Pampelune* (14th century, based on a lost *chanson*); and *Gui de Bourgogne* (12th century) tells how the children of the barons, after appointing Guy as king of France, set out to find and rescue their fathers, who are represented as having been fighting in Spain for 27 years. The *Chanson de Roland* relates the historic defeat of Roncevalles on Aug. 15, 778, and forms the very crown of the whole Carolingian legend. The two 13th-century romances, *Gaidon* and *Anseis de Carthage*, contain a purely fictitious account of the end of the war in Spain, and of the establishment of a Frankish kingdom under the rule of Anseis. Charlemagne was recalled from Spain by the news of the outbreak of the Saxons. The contest between Charlemagne and Widukind (*Guiteclin*) offered abundant epic material. Unfortunately the original *Guiteclin* is lost, but the legend is preserved in *Les Saisnes* (c. 1300) of Jehan Bodel, which is largely occupied by the loves of Baudouin and Sibille, the wife of Guiteclin. The adventures of Blanchefleur, wife of Charlemagne, form a variation of the common tale of the innocent wife falsely accused, and are told in *Macaire* and in the extant fragments of *La Reine Sibille* (14th century). After the conquest of the Saracens and the Saxons, the defeat of the Northmen, and the suppression of the feudal revolts, the emperor abdicated in favour of his son Louis (*Le Couronnement Loosy*, 12th century). Charles's harangue to his son is in the best tradition of epic romance. The memory of Roncevalles haunts him on his death-bed, and at the moment of death he has a vision of Roland.

The mythic element is practically lacking in the French legends, but in Germany some part of the Odin myth was associated with Charles's name. The constellation of the Great Bear, generally associated with Odin, is *Karlswagen* in German, and Charles's Wain in English. There were mediaeval chroniclers who did not fear to assert that Charles rose from the dead to take part in the Crusades. In the ms. *Annales S. Stephani Frisingenses* (15th century), which formerly belonged to the abbey of Weihenstephan, and is now at Munich, the childhood of Charlemagne is practically the same as that of many mythic heroes. This work, generally known as the chronicle of Weihenstephan, gives among other legends a curious history of the emperor's passion for a dead woman, caused by a charm given to Charles by a serpent to whom he had rendered justice. The charm was finally dropped into a well at Aix, which thenceforward became Charles's favourite residence. The story of Roland's birth from the union of Charles with his sister Gilles, also found in German and Scandinavian versions, has abundant parallels in mythology, and was probably transferred from mythology to Charlemagne.

The Latin chronicle, wrongly ascribed to Turpin (Tilpinus), bishop of Reims from 753 to 800, was in reality composed by a Frenchman between 1140 and 1150. Alberic Trium Fontium, a monk of the Cistercian monastery of Trois Fontanes in the diocese of Châlons, embodied much poetical fiction in his chronicle (c. 1249). A large section of the *Chronique rimée* (c. 1243) of Philippe Mousket is devoted to Charlemagne's exploits. At the beginning of the 14th century Girard of Amiens made a dull compilation known as *Charlemagne* from the *chansons de geste*, authentic history and the pseudo-Turpin. *La Conquête que fit le grand roi Charlemagne es Espaignes* (pr. 1486) is the same work as the prose compilation of *Fierabras* (pr. 1478), and Caxton's *Lyf of Charles the Grete* (1485).

The Charlemagne legend was fully developed in Italy, where it was to have later a great poetic development at the hands of Boiardo, Ariosto and Tasso. There are two important Italian compilations, ms. XIII. of the library of St. Mark, Venice (c. 1200), and the *Reali di Francia* (c. 1400) of a Florentine writer, Andrea

da Barberino (b. 1370), edited by G. Vandelli (Bologna, 1892). The six books of this work are rivalled in importance by the ten branches of the Norse *Karlamagnus saga*, written under the reign of Haakon V. This forms a consecutive legendary history of Charles, and is apparently based on earlier versions of the French Charlemagne poems than those which we possess. It thus furnishes a guide to the older forms of stories, and moreover preserves the substance of others which have not survived in their French form. A popular abridgement, the *Keiser Karl Magnus Krönike* (pr. Malmö, 1534), drawn up in Danish, serves in some cases to complete the earlier work. The 2,000 lines of the German *Kaiserchronik* on the history of Charlemagne belong to the first half of the 12th century, and were perhaps the work of Conrad, the poet of the *Ruolantes Liet*. The German poet known as the Stricker used the same sources as the author of the chronicle of Weihenstephan for his *Karl* (c. 1230). The earliest important Spanish version was the *Chronica Hispaniae* (c. 1284) of Rodrigo de Toledo.

The French and Norman-French *chansons* circulated as freely in England as in France, and it was therefore not until the period of decadence that English versions were made. The English metrical romances of Charlemagne are:—*Rowlandes Song* (15th century); *The Taill of Rauf Coilyear* (c. 1475, pr. by R. Lekpreuk, St. Andrews, 1472), apparently original; *Sir Ferumbras* (c. 1380) and the *Sowdone of Babylone* (c. 1400) from an early version of *Fierabras*; a fragmentary *Roland and Vernagu* (Ferragus); two versions of *Otuel* (Otinél); and a *Sege of Melayne* (c. 1390), forming a prologue to *Otinél* unknown in French.

For the historical Charlemagne see CHARLES THE GREAT.

BIBLIOGRAPHY.—The most important works on the Charlemagne cycle of romance are J. Bédier, *Les légendes épiques* (4 vol., 1908–13) and *La Chanson de Roland* (1927), and for the German legend, vol. iii. of H. F. Massmann's ed. of the *Kaiserchronik* (Quedlinburg, 1849–54). The English Charlemagne romances were edited (extra series) for the Early Eng. Text Soc. by Sidney J. Herrtage, Emil Hausknecht, Octavia Richardson and Sidney Lee (1879–81), the romance of *Duke Huon of Bordeaux* containing a general account of the cycle by Sidney Lee; the *Karlamagnussaga*, by C. R. Unger (Christiania, 1860); see also G. Paris in *Bibl. de l'Ecole des Chartes* (1864–65). For individual *chansons* see L. Gautier, *Les Épopées françaises* (new ed. 1919 etc.) and J. Bédier, *op. cit.*, to which the following should be added: A. Thomas, *L'Entrée d'Espagne* (Société des Anciens Textes Français, 1913); L. Brandin, *La Chanson d'Aspremont* (1923–24), and *Sir Otuel*, ed. S. J. Herrtage (E.E.T.S., 1880). For the Carolingian romances relating to Roland, see *ROLAND*; *Les Saisnes*, ed. F. Michel (1839); *The Sege of Melaine*, introductory to *Otinél*, preserved in English only (ed. E.E.T.S., 1880); *Simon de Pouille*, analysis in *Epop. fr.* (iii. pp. 346 seq.); *Voyage de C. à Jérusalem*, ed. E. Koschwitz (Heilbronn, 1879). For the chronicle of the Pseudo-Turpin, see an edition by Castets (Paris, 1881) for the "Société des langues romanes," and J. Bédier in *Légendes épiques*, t. iii. The Spanish versions of Carolingian legends are studied by Milá y Fontanals, *De la poesia heroico-popular castellana* (Barcelona, 1874).

CHARLEMONT, JAMES CAULFEILD, 1ST EARL OF (1728–1799), Irish statesman, son of the third viscount Charlemont, was born in Dublin on Aug. 18, 1728, and succeeded his father as fourth viscount in 1734. Lord Charlemont is historically interesting for his political connection with Flood and Grattan. For various early services in Ireland he was made an earl in 1763, but he disregarded court favours and cordially joined Grattan in 1780 in the assertion of Irish independence, being chosen commander-in-chief of the volunteer force. He was president of the volunteer convention in Dublin in November 1783, and was a strong opponent of the proposals for the Union. Lord Charlemont was a cultivated man, with liberal and artistic tastes, and his house was a centre of literary society in Dublin. He died on Aug. 4, 1799.

See F. Hardy, *Memoirs of the political and private life of James Caulfeild, Earl of Charlemont* (1810; 2nd ed., 1812); *Original Letters, principally from Lord Charlemont, . . . Edmund Burke, . . . etc.* (1820).

CHARLEROI (CAROLUS REX), a town in the province of Hainaut, Belgium. Pop. (1925) 27,395. It was founded in 1666 on the site of a village called Charnoy, by the Spanish governor Roderigo, and named after his sovereign Charles II. of Spain. Charleroi is the centre of the chief coalfield of Belgium, with im-

portant metallurgical and glass industries. It is connected by canal with Brussels, and from its position on the Sambre communicates by water with France. It was ceded soon after its foundation to France by the treaty of Aix-la-Chapelle, and Vauban fortified it. During the French occupation the town was considerably extended, and its fortifications strengthened to resist the attacks of William of Orange. In 1794 Charleroi again fell into the hands of the French, and it was dismantled by them. In 1816 it was re-fortified under Wellington's direction, but was finally dismantled in 1859. Parts of the old ramparts are left near the railway station. The battle of Charleroi (Aug. 22-23, 1914) was fought on the banks of the Sambre between the V. German Army and the retreating French troops.

CHARLEROI, a borough of Washington county, Pennsylvania, U.S.A., on the Monongahela river, 23m. S. by E. of Pittsburgh; served by the Pennsylvania railroad. The population in 1920 was 11,516 (26% foreign-born white), and was 11,260 in 1930 by the Federal census. It is in the "Pittsburgh" coal-field, and has important manufactures of steel, plate-glass, lamp chimneys and bottles. The factory output in 1925 was valued at \$4,498,968. Charleroi was founded in 1890.

CHARLES, a masculine proper name (Fr. *Charles*; Span. *Carlos*; Ital. *Carlo*; Ger. *Karl*), meaning originally "man." It has been borne by many European sovereigns and princes.

CHARLES (1525-1574), cardinal of Lorraine, French statesman, was the second son of Claude of Lorraine, duke of Guise, and brother of Francis, duke of Guise. He was archbishop of Reims in 1538 and cardinal in 1547. At first he was called the cardinal of Guise, but in 1550, on the death of his uncle John, cardinal of Lorraine, he in his turn took the style of cardinal of Lorraine. A master of intrigue, he was, like all the Guises, ambitious and devoid of scruples. With his brother, Duke Francis, the cardinal was all-powerful during the reigns of Henry II. and Francis II.; in 1558 and 1559 he was one of the negotiators of the treaty of Cateau-Cambrésis; he persecuted the reformers pitilessly and helped to provoke the crisis of the wars of religion. The death of Francis II. deprived him of power, but he remained one of the principal leaders of the Catholic party. In 1561, at the Colloquy of Poissy, he was commissioned to reply to Theodore Beza (*q.v.*). In 1562 at the Council of Trent, he at first defended the rights of the Gallican Church against the pretensions of the pope; but after the assassination of his brother he approached the court of Rome, and on his return to France he endeavoured, in vain, to obtain the promulgation of the decrees of the council (1564). In 1567, when the Protestants took up arms, he held for some time the first place in the king's council, but Catherine de' Medici soon grew weary of his arrogance and in 1570 he had to leave the court. He endeavoured to regain favour by negotiating at Rome the dispensation for the marriage of Henry of Navarre with Margaret of Valois (1572). He died on Dec. 26, 1574, at the beginning of the reign of Henry III.

A large amount of correspondence is preserved in the Bibliothèque Nationale. See also J. J. Guillemin, *Le Cardinal de Lorraine* (1847); René de Bouillé, *Histoire des ducs de Guise* (1849); H. Forneron, *Les Guises et leur époque* (1877); H. N. Williams, *The Brood of False Lorraine* (1918).

CHARLES, ST., called **THE GOOD** (le Bon), or **THE DANE** (c. 1084-1127), count of Flanders, was the only son of St. Canute or Knut IV., king of Denmark, by Adela, daughter of Robert the Frisian, count of Flanders. On the assassination of Canute in 1086, his widow fled to Flanders, with her son. Charles was brought up by his mother and grandfather, Robert the Frisian, on whose death he did great services to his uncle, Robert II., and his cousin, Baldwin VII., counts of Flanders. Baldwin died of a wound in 1119, and, having no issue, left his countship by will to Charles the Dane. Charles had to fight for his heritage, but he soon won, and secured his position by his clemency. He devoted himself to the welfare of his subjects, and exerted himself in the cause of Christianity, both by his bounty and by his example. He well deserved the surname of *Le Bon*. He refused the crown of Jerusalem on the death of Baldwin, and in 1125 nomination as a candidate for the imperial crown in succession to Henry V. He was murdered while praying in the church of St. Donatian

at Bruges on March 2, 1127, because, by throwing open granaries there in a famine, he had broken the merchants' monopoly.

See J. Perneel, *Histoire du Règne de Charles le Bon, précédé d'un résumé de l'histoire de Flandres* (Brussels, 1830), and *Charles le Bon, Comte de Flandre* (Lille, 1853).

CHARLES THE GREAT (CHARLEMAGNE), king of the Franks and emperor, born April 2, 742 or 743, was the eldest son of Pepin III. by Berta (Bertrada), daughter of Charibert of Laon. At that date the Franks were governed by Pepin and his brother Carloman, who ruled as mayors of the palace under a fainéant Merovingian king. By the abdication of Carloman, in 747, Pepin became sole ruler, as his father Charles Martel had been. In 751 Pepin deposed the last Merovingian (Childeric III.) and himself assumed the Frankish crown, with the approbation of Pope Zacharias. In 754 Pope Stephen II. visited Pepin at Paris and anointed him as king, together with his two sons, Charles and Carloman. Between these two the kingdom was equally divided by Pepin on his death-bed (768), Charles receiving Austrasia, Neustria and western Aquitaine. This arrangement was displeasing to his junior, who perhaps claimed the whole inheritance on the ground that he was born after their father's coronation (751). In 769 Charles suppressed an Aquitanian rising, led by the aged Duke Hunold, and received the submission of Lupus, duke of Gascony, although Carloman declined to give any assistance. In 770 Charles married the daughter of Desiderius, king of the Lombards, probably to strengthen the influence which Pepin III. had acquired in Italian politics. But in 771 he repudiated the Lombard princess and married Hildegard, a Suabian lady, who became the mother of his three legitimate sons, Charles, Pepin and Lewis. Desiderius naturally resented the slight put upon his daughter and seized the first opportunity of revenge. This presented itself in 771, when King Carloman died and Charles, in accordance with Frankish law, appropriated the vacant kingdom to the exclusion of his brother's infant sons. Their mother, Queen Gerberga, fled with them to the court of Desiderius, who announced his intention of supporting their claims and vainly urged the pope to crown them (772). Hadrian, who had lately succeeded Stephen II., endangered the safety of the papal States by refusing this demand, since Charles was preoccupied with his first Saxon campaign, and Desiderius plundered and conquered at his will in central Italy. But in the autumn of 772 Charles gave ear to Hadrian's appeal for help, and demanded satisfaction from the Lombards for himself and for the pope. Since Desiderius was defiant, the Frankish host was summoned to meet at Geneva in May 773. From Geneva the main army, led by Charles himself, marched over the Mt. Cenis to Susa, where it encountered the Lombard army, under Desiderius, holding a fortified position, and was brought to a halt. Meanwhile a second Frankish army, which had crossed the Great St. Bernard, threatened the communications of the Lombards, who as soon as they perceived their danger fell back in haste, some to Pavia and others to Verona. Verona surrendered to the Franks in the winter of 773-774, and here the nephews of Charles fell into his hands. Their fate is uncertain, but they troubled him no more. Pavia was reduced, after a long blockade, in the following summer. Desiderius, who was found there, ended his days as a monk at Corbie on the Somme. After the fall of Pavia Charles took the title of king of the Lombards. Frankish garrisons and Frankish officials were established at Pavia and in other cities of the kingdom. But some of the Lombard dukes in north and central Italy were allowed to remain in office as vassals of the conqueror. The ducal house of Benevento remained *de facto* independent, though in 788 the reigning duke agreed to pay an annual tribute, to date his charters by the regnal years of Charles, and to inscribe the name of Charles upon his coinage. Charles abstained from meddling with the Greek possessions in south Italy—Calabria, Apulia, Naples, Salerno, Amalfi. But later in his reign he acquired the Greek provinces of Venetia, Istria and Dalmatia. His relations with the papacy were defined during a visit which he paid to Rome at the Easter feast of 774. He was then acclaimed as Patrician of the Romans, and he confirmed the so-called Donation of 754 by which his father had guaranteed to the papacy its ancient and law-

ful possessions in Italy. The text of the Donation only survives in a corrupt and interpolated copy. It cannot have been precisely worded since Hadrian and Charles, who were otherwise good friends, differed sharply about its interpretation. As Patrician, Charles claimed the right of hearing appeals from the Roman law-courts, and he exacted an oath of allegiance from the Romans when Hadrian's successor was elected, though he did not interfere with the election. In 800 he presided over the tribunal before which Leo III. purged himself of various accusations. But it was Lewis the Pious who first established (in 824) the right of the emperor to supervise the temporal administration of the pope through an envoy permanently residing in Rome.

From 774 to 799 Charles was at war with the Saxons, a heathen race whose lands lay east of the Rhine and north of Hesse and Thuringia. Though troublesome neighbours of the Franks they had become tributaries of Pepin III. in 758, and the Frankish annalists do not explain the first Saxon war of Charles (in 772) by reference to any provocation that he had received. Their paganism may have been their chief offence; the chief event of the campaign was the destruction of the sacred pillar Irminsul, together with its grove and temple. The Saxons retaliated by raiding Hesse while Charles was absent in Italy, and on his return, in 775, he opened a war of conquest which was only completed in the 14th campaign. There was no cohesion between the Saxon tribes, and they were much inferior to the Franks in military science and equipment. But their country had strong natural defences (the hills and forests of the Teutoburger Wald and the Harz country, the Weser and the Elbe with their tributary streams) which made it difficult for the Franks to invade rapidly or to retreat with impunity. The Frankish host was only available in the summer months, and it was difficult to find garrisons for conquered districts. The Saxons usually offered submission when they were attacked in force, and rebelled again when Charles withdrew his forces. He did not make his difficulties lighter when he insisted that those who submitted should accept baptism. His chief opponent was the Westphalian chieftain Widukind who, in 778, raided the east bank of the Rhine up to Coblenz, and, in 782, destroyed a Frankish punitive force in Saxony. The second of these exploits was atrociously revenged in the massacre of Verden, where Charles put to the sword no less than 4,500 Saxon captives in one day. In 785 Widukind submitted upon terms and was baptized, after Charles had wintered in Saxony, and had harried the land continuously for some months. After this year the chief centres of resistance were the marshes on the left bank of the lower Elbe and Nordalbingia (Schleswig). To these districts Charles applied in 799 and 804 a policy of deportations, transplanting combatants and non-combatants alike to other parts of his empire. He legislated for the conquered lands on more than one occasion. His *Capitulatio de Partibus Saxoniae* (probably of 785) denounces penalties of the severest kind against idolators and those who wrong churches or ecclesiastics; it also obliges the whole population to pay tithes to the Church. His *Capitulare Saxonicum* (797), issued after consultation with representatives of the Saxons, modifies in some respects the customary law of the race, to make it conformable with Frankish law. The customary law itself is recorded in his *Lex Saxonum*, of uncertain date. Charles founded in Saxony the bishoprics of Munster, Minden, Osnabrück, Paderborn and Bremen. He appointed Saxon nobles as his counts, and required them to hold law-courts in the Frankish manner. He directed the clergy to report to himself those counts who perverted the course of justice. In or before 797 he began to send his *missi dominici* to perambulate in Saxony. No public assembly of the Saxons was lawful unless convoked by these officials. Under this system Saxony was tranquil after 804. In the ninth century the Saxons, while retaining much of their primitive law and culture, became fervently Christian and thoroughly reconciled to Frankish rule.

Bavaria was annexed by Charles more easily and earlier than Saxony. Tassilo, the last Bavarian duke of the Agilolfing line received the duchy in 748 from the hands of Pepin III., to whom he took the oath of fealty; but he persistently absented himself from the annual assembly, and took no part in the campaigns of

Pepin or of Charles. Under pressure he renewed his fealty in 781 and 787. But on the second occasion he only took the oath when the Frankish host was on the march to invade Bavaria, and in 788 he was indicted before the assembly for conspiring with the Avars. His life was spared, but he was relegated to a monastery, and Bavaria was divided between Frankish counts. In the 9th century the Bavarians were the chief support of the East Frankish monarchy and Regensburg was the chief residence of Lewis the German. As the master of Bavaria Charles came into collision with the Avars, who had been settled in the Hungarian steppes since 568. In 791 he harried their western lands, between the rivers Enns and Raab. The fortified camp (Ring) of the Avar Khan was sacked in 795 by the Margrave Eric of Friuli, and totally destroyed by Pepin, the second son of Charles in 796. After this disaster the Avars sent to Aachen certain of their chiefs who made peace and accepted baptism. Bishop Arno of Salzburg was commissioned by Charles to convert the Avar nation, and in 805 the Khan, finding himself hard pressed by the Slavs, became a Christian and placed himself under the emperor's protection.

More celebrated, but historically less important, than this easterly expansion of Frankish power is the campaigning with which Charles and his lieutenants harassed the Arabs of northern Spain. In 778 Charles himself commanded an expedition against Saragossa. It was a failure, since he did not receive the support which he had expected from some rebellious emirs. As he was retreating through the Pyrenees his rear-guard was destroyed, not by the Arabs, but by the Christian Basques of Pampeluna, whom he had exasperated by destroying the walls of that city. Einhard the biographer of Charles, treats this disaster as insignificant; but the fate of Roland, the Warden of the Breton march, who fell at Roncesvaux with other famous warriors (Aug. 15, 778), passed into legend and song. To repair his relations with the Spanish Christians Charles took their side in the Adoptionist controversy, when they indicted the archbishop of Toledo as a heretic. He desired to create a Frankish march on the south slope of the Pyrenees, as an outwork for the defence of Narbonne and Septimania; and in this object he succeeded. In 801 Barcelona was captured by his son Lewis with the help of Count William of Toulouse, a hero whose name, like that of Roland, lives in mediaeval epic. In 807 Pampeluna accepted the protection of Charles and became the second bastion of the "Spanish Mark," which effectively defended both the western and the eastern passes of the Pyrenees.

Only thrice between 774 and 799 did Charles revisit Italy. In each case his primary object was to tighten his hold upon the Lombard kingdom. In 775 he crushed a Lombard rebellion in which the dukes of Friuli, Chiusi and Spoleto were supported by their compatriot, the independent ruler of Benevento; Rotgaud of Friuli lost his duchy, and Hildebrand of Spoleto, who had placed himself under the Pope's protection in 773, was forced to become a royal vassal. In 780 and in 787 Charles crossed the Alps to assert his supremacy over Benevento, an object, which, as already noted, he did not completely realize. During the second of these three visits he induced Pope Hadrian to crown his sons Pepin and Lewis as kings of Italy and Aquitaine. The Teutonic lands he reserved for himself and for his eldest son and namesake. These arrangements suggest that Italian affairs did not occupy the first place in his thoughts and calculations; and it is significant that, even after his imperial coronation, he held to the plan of 780. In this same year, while still in Italy he accepted the suggestion of the Empress Irene that his eldest daughter Rotrude should marry Irene's son and ward, the young Constantine VI. But Charles repudiated this arrangement in 787, probably because Irene and her son in that year induced the Seventh Council of Nicaea to restore image worship in the Greek Church, and called upon the Latin Church to imitate a policy which Charles and the Frankish clergy regarded as superstitious and absurd. Pope Hadrian, whose legates were present at the Council of Nicaea, agreed with its decision, but his wishes were ignored by the king. In 794 Charles held a council of the Frankish Church at Frankfurt to refute the worshippers of images. It was attended by Papal envoys and representatives of the Italian, Spanish, and English clergy. The arguments on which Charles and his advisers

relied are set forth in the *Libri Carolini*, four tracts composed in the years 789-791 by the king's orders, and published in his name. It is uncertain whether Charles was inspired by religious zeal or by a desire to discredit the Greek empire. The *Libri Carolini* expressly dispute the right of Constantine VI. to be regarded as the lawful heir of the *Imperium Romanum*; but there is no other evidence to suggest that Charles at this time coveted the imperial dignity. Perhaps the long struggle for the extirpation of Saxon idolatry was responsible for the vigour with which he and the Frankish Church pursued this controversy. There was no irremediable rupture of relations with the Greek empire; for in 798 Irene sent ambassadors to Aachen to inform Charles that Constantine VI. had been deposed and that she had been acknowledged as her son's successor. Among the Frankish clergy it appears to have been the accepted view that Constantine was infamously treated and that a woman was incapable of holding the empire. There is nothing to suggest that Irene's ambassadors were discourteously received. But in 800 Charles allowed himself to be crowned as emperor at Rome by Pope Leo III.

The secret history of this coronation, and the motives of those who counselled it, can only be conjectured. Leo III., the successor of Hadrian, was freely elected by the Roman clergy and people in 795. Charles readily acknowledged the validity of the election, but until 799 we hear of no further correspondence between the papal and the Frankish courts. In 799 a Roman faction, who accused Leo of adultery and perjury, endeavoured to get rid of him. Brutally assaulted in the streets of Rome, he narrowly escaped the loss of tongue and eyes and was confined in a Roman monastery; but his attendants succeeded in conveying him to the Duke of Spoleto for protection. Leo's character was unfavourably judged by some of the Frankish clergy; for which reason Charles declined to reinstate him until the accusations of his enemies were disproved. In July 799 Leo was brought to the king at Paderborn, ostensibly as an honoured guest, and remained there for some days. He was finally sent back to Rome, escorted by a commission of archbishops, bishops and counts, who held a judicial enquiry and reported that nothing had been proved against the Pope. In Nov. 800 the king appeared at Rome, and spent more than three weeks in reviewing the situation. His chief difficulty, we are told, was still to decide how he would deal with the pope. No accuser dared to state a case against Leo, but it is evident that he was not generally popular in Rome. At last, on Dec. 23, Leo cleared himself in St. Peter's church, taking a solemn oath upon the Gospels, that he was innocent. On Christmas Day, after celebrating mass in the same church, he crowned Charles as emperor in the presence of the Roman people who were evidently not taken by surprise, since they acclaimed Charles in the set form of words which was used to welcome a patrician. Two theologians of the emperor, Anghilbert and Alcuin prophesied obscurely (in prose and verse) the imperial coronation some months before it actually occurred. Charles may have hesitated to run the risk of a war with Constantinople; but the biographer's statement, that he was crowned unawares and against his will, is not convincing.

Once crowned, he showed himself ready and eager to come to some arrangement with Constantinople. In 801 he made an offer of marriage to Irene, but she was deposed shortly after his envoys arrived at the Greek court. They were well treated by her successor Nicephorus I., who made counter-proposals for an honourable peace between West and East. Charles responded amicably and proposed a boundary line which would have given him Venetia, and the coast towns of Istria and Dalmatia. But Nicephorus preferred to fight for these newly lost provinces, and there ensued a naval war in the Adriatic, conducted on the Frankish side by King Pepin. After the death of Pepin (July 8, 810) Charles hurriedly offered peace, with the surrender of all his claims to the disputed territories. The offer was accepted by Michael Rhangabé, who succeeded Nicephorus in 811; and in 812 Greek envoys came to Aachen and saluted the emperor of the West as *Basileus*, thus acknowledging the equality of the two empires. In view of these facts it cannot reasonably be contended that Charles regarded the Roman empire as indivisible.

In 806 Charles, in accordance with Frankish custom, drew up a scheme for the partition of his realms between his three legitimate sons. It provided that each son should be absolute in his own sphere, and did not designate a successor to the empire. But in 813, when peace had been made with Constantinople, and Charles the Young and Pepin were dead, he nominated Lewis the Pious as his consort and successor in the empire, at the same time assigning Italy to Bernhard the son of Pepin. Charles thus asserted the hereditary character of the empire. It is remarkable that the coronation of Lewis took place, not at Rome, but at Aachen, and that Charles himself placed the crown upon his son's head, as if with the intention of showing to the world that the pope had no voice in the disposal of the empire. Next to the Greeks the Danes were the chief enemies with whom Charles had to deal in his last years. A Danish kingdom was already in existence, and it menaced his north-eastern frontier; Danish pirates were already harrying the British Isles. In 809 Charles built a fort at Itzehoe to protect the right bank of the Elbe. In 811 and 812 he concluded treaties with Danish kings. But he relied especially upon his North sea fleet which was based upon Boulogne, and built in his shipyards at Ghent. He ordered that ships should be found for defence of all ports and navigable rivers on his northern coasts. He also maintained patrols in the Mediterranean from Narbonne to the mouth of the Tiber, to guard against the descents of Arab pirates, but the danger from this side did not engage his personal attention. By capitularies of 802 and 811 he made naval service obligatory on all the inhabitants of maritime provinces, even upon the magnates. It was no fault of his that the Franks failed to create a strong naval power against the evil days that were in sight.

The reign of Charles witnessed a revival of arts and letters in Francia. Illuminators, goldsmiths, workers in ivory and metal reached a high degree of skill, although the higher arts were still neglected, and the emperor's chapel at Aachen was adorned with pillars and bronze portals fetched from Rome and Ravenna. Among the Frankish clergy scholarship was encouraged in the reign of Pepin, by the king himself and by the Englishman Boniface, archbishop of Mainz. Charles stimulated the clergy to further efforts. He himself studied Latin grammar with Peter of Pisa, rhetoric and dialectic and astronomy with Alcuin of York, and he listened with attention while his clerks read to him works of history or St. Augustine's *De Civitate Dei*. The effect of classical studies, upon Charles himself and his advisers, is revealed in his legislation which is more grammatically and intelligently composed than those of his predecessors. He aspired to emulate the legislators of Constantinople. Though he never attempted to make a code, he revised the laws of the Salian and Riparian Franks, and caused those of the Saxons, Thuringians and Frisians to be written down. His Capitularies, which were binding on his subjects without respect of race, supply a remarkable conspectus of Frankish institutions. In these texts we can study the duties of his counts and *missi*, the functions of the local law courts and assemblies, the law of vassalage, the rights of exempted estates (*immunitates*), the composition of the national host; the *Capitulare de Villis* even supplies full information concerning the management of the royal demesnes. The credit for the details of this legislation is due to the arch-chaplain and the clerks of the royal chaplain, ecclesiastics who were trained in seminaries of the Carolingian renaissance. By his *Admonitio Generalis* (789) Charles required that every bishop should test the theological education of his priests, and that reading schools should be everywhere established. For a select minority a higher type of education was provided in cathedral schools, such as those of Orleans and Lyons, and in such monastic schools as those of Tours, Corbie, St. Riquier, Metz and St. Wandrille. The Palace school, a Merovingian institution, was reorganized by Alcuin in the years 782-796. In it were educated the emperor's children, the sons of great nobles and also some ecclesiastics who afterwards did much to promote the new studies, as for example Adalhard of Corbie and Anghilbert of St. Riquier. The Palace school declined after the death of Charles, but the new cathedral and monastic schools produced a remarkable race of literati. To the libraries founded

in connection with such schools we are indebted for the oldest extant manuscripts of Caesar, Sallust, Lucretius, Tacitus and Suetonius, and many of the works of Cicero. In the emperor's lifetime, and with his encouragement, the text of the Latin Vulgate was restored to a purer form by Alcuin and other scholars. One of these recensions not the work of Alcuin, was officially recommended to the Frankish bishops by the encyclical *De Emendatione Librorum* (c. 787). The scholars whom Charles patronized are well remembered as excellent grammarians. In their hands Latin became once more a polished and flexible medium of literary expression. The thoughts which they expressed in copious prose and verse are often banal pleasantries or insipid exhortations. Alcuin's letters, a few topical poems by Alcuin and Theodulf of Orleans, and the biography of Charles by Einhard, one of the royal clerks, are the cream of this Carolingian literature.

At Aachen he built a palace (of which no trace is left) and a chapel which, with many alterations and restorations, is incorporated in the existing cathedral. He commenced to build another palace at Ingelheim near Mainz, which was the great bridge-head for his armies, and a third at Nymwegen (near the Saxon border) of which the chapel, consecrated by Leo III., is the only relic. For three years, 792–794, he settled at Regensburg, the old Bavarian capital, but this step was taken for political and military reasons. At Aachen he was in his homeland. The forests of the neighbourhood gave him good hunting; with his sons and his nobles and his bodyguards he bathed and swam in the hot springs which still feed the *Kaiserbad*. In his dress, as in his pastimes, he affected the old Frankish mode, and he disdained elaborate banquets, preferring a simple, heavy meal at which the staple dish was broiled venison, served to him on the spit by his huntsmen. When business of State was in hand he was prompt, methodical and labourious. He prided himself on the magnificent furniture of his chapel and on the decorum with which its services were celebrated. He kept to the end his interest in scholarship and in theology, and left a large library of manuscripts. But his private life was lax in one respect. Though a devoted husband to three of his four wives, he had illegitimate offspring by five mistresses. His court was dissolute and the conduct of his daughters caused grave scandals.

Charles died on Jan. 28, 814, after four years of failing health, from an attack of pleurisy. He was buried in the chapel at Aachen, probably in the antique sarcophagus which is preserved there; this at all events is the coffin in which his bones were found in 1165, when they were disinterred by Frederick Barbarossa.

CHARLES II.,¹ called **THE BALD** (823–877), Roman emperor and king of the West Franks, the son of the emperor Louis the Pious, was born in 823. The death of the emperor in 840 was the signal for the outbreak of war between his sons. Charles allied himself with his brother Louis the German to resist the pretensions of the emperor Lothair, and the two allies conquered him in the bloody victory of Fontenoy-en-Puisaye (June 25, 841). In the following year the two brothers confirmed their alliance by the celebrated oaths of Strasbourg (see *FRANCE: History*). The war was brought to an end by the treaty of Verdun (Aug. 843), which gave to Charles the Bald the kingdom of the western Franks, which practically corresponded with what is now France, as far as the Meuse, the Saône and the Rhone, with the addition

¹For Charles I., Roman emperor, see *CHARLEMAGNE*; cf. under Charles I. of France below.

of the Spanish March as far as the Ebro. The first years of his reign up to the death of Lothair I. (855) were comparatively peaceful, and during them was continued the system of "confraternal government" of the sons of Louis the Pious, who had various meetings with one another, at Coblenz (848), at Meerssen (851), and at Attigny (854). In 858 Louis the German invaded the kingdom of Charles. In 860 he in his turn tried to seize the kingdom of his nephew, Charles of Provence, but met with a repulse. On the death of Lothair II. in 869 he tried to seize his dominions, but by the treaty of Meerssen (870) was compelled to share them with Louis the German. Besides this, Charles had to struggle against the incessant rebellions in Aquitaine, against the Bretons, who inflicted on the king the defeats of Ballon (845) and Juvardel (851), and especially against the Normans, who devastated the country in the north of Gaul, the valleys of the Seine and Loire, and even up to the borders of Aquitaine. Charles led various expeditions against the invaders, and tried to put a barrier in their way by having fortified bridges built over all the rivers. In 875, after the death of the emperor Louis II., Charles the Bald, supported by Pope John VIII., descended into Italy, receiving the royal crown at Pavia and the imperial crown at Rome. But Louis the German revenged himself for Charles's success by invading and devastating his dominions. Charles was recalled to Gaul, and after the death of Louis the German (Aug. 28, 876), in his turn made an attempt to seize his kingdom, but at Andernach met with a shameful defeat (Oct. 8, 876). In the meantime, John VIII., who was menaced by the Saracens, was continually urging him to come to Italy, and Charles again crossed the Alps. At the same time Carloman, son of Louis the German, entered northern Italy. Charles started on his way back to Gaul, and died while crossing the pass of the Mont Cenis, Oct. 5 or 6, 877. He was succeeded by his son Louis the Stammerer.

BIBLIOGRAPHY.—The most important authority for the history of Charles's reign is represented by the *Annales Bertiniani*, which were the work of Prudentius, bishop of Troyes, up to 861, then up to 882 of the celebrated Hincmar, archbishop of Reims. This prince's charters are to be found published in the collections of the *Académie des Inscriptions*, by M. M. Prou. The most complete history of the reign is found in E. Dümmler, *Geschichte des ostfränkischen Reiches* (3 vols., Leipzig, 1887–88). See also J. Calmette, *La Diplomatie carolingienne du traité de Verdun à la mort de Charles le Chauve* (Paris, 1901), and F. Lot, "Une Année du règne de Charles le Chauve," in *Le Moyen-Âge* (1902), pp. 393–438; F. Lot and L. Halphen, *Le Règne de Charles le Chauve* (1909); M. Jusselin, *La Chancellerie de Charles le Chauve d'après les notes tironiennes* (1922).

CHARLES III., **THE FAT** (832–888), Roman emperor and king of the West Franks, was the youngest of the three sons of Louis the German, and received from his father the kingdom of Swabia (Alamannia). After the death of his two brothers in succession, Carloman (881) and Louis the Young (882), he inherited the whole of his father's dominions. He was crowned emperor at Rome by Pope John VIII. (Feb. 881). On his return to Germany he led an expedition against the Norsemen of Friesland, but instead of engaging with them he preferred to make terms and paid them tribute. In 880 the death of Carloman brought into his possession the west Frankish realm, and in 885 he got rid of his rival Hugh of Alsace, an illegitimate son of Lothair II. In spite of six expeditions into Italy, he did not succeed in pacifying the country, nor in delivering it from the Saracens. He was equally unfortunate in Gaul and in Germany against the Norsemen, who in 886–887 besieged Paris. The emperor appeared before the city with a large army (Oct. 886), but contented himself by buying the retreat of the invaders at the price of a heavy ransom, and his permission for them to ravage Burgundy without his interfering. On his return to Alamannia the general discontent showed itself openly and a conspiracy was formed against him. He was deposed by an assembly which met at Frankfurt or at Tribur (Nov. 887), and died in poverty at Neidingen on the Danube (Jan. 18, 888).

CHARLES IV. (1316–1378), Roman emperor and king of Bohemia, the eldest son of John of Luxemburg, king of Bohemia,

and Elizabeth, sister of Wenceslas III., was born at Prague on May 14, 1316, and in 1323 went to the court of his uncle, Charles IV., king of France, where he remained for seven years. He married Blanche, sister of King Philip VI., the successor of Charles IV. In 1333 he was made margrave of Moravia. Three years later he undertook the government of Tirol on behalf of his brother John Henry, and was soon actively concerned in a struggle for the possession of this country. In consequence of an alliance between his father and Pope Clement VI., the relentless enemy of the emperor Louis IV., Charles was chosen German king in opposition to Louis by some of the princes at Rense on July 11, 1346. Confirming the papacy in the possession of wide territories, he promised to annul the acts of Louis against Clement, to take no part in Italian affairs, and to defend and protect the church. In 1346 he fought at Crécy, where his father was killed. As king of Bohemia he returned to Germany, and after being crowned German king at Bonn on Nov. 26, 1346, prepared to attack Louis. After the death of the emperor in October 1347 Charles was soon the undisputed ruler of Germany.

In 1350 the king was visited at Prague by Cola di Rienzi, who urged him to go to Italy, where the poet Petrarch and the citizens of Florence also implored his presence. Charles kept Rienzi in prison for a year, and then handed him over to Clement at Avignon. Four years later, however, he crossed the Alps without an army, received the Lombard crown at Milan on Jan. 6, 1355, and was crowned emperor at Rome by a cardinal on April 5. On his return Charles was occupied with the administration of Germany, then just recovering from the Black Death, and in 1356 he promulgated the Golden Bull (*q.v.*) to regulate the election of the king. He was unremitting in his efforts to secure other territories and to strengthen the Bohemian monarchy. To this end he purchased part of the upper Palatinate of the Rhine in 1353, and in 1367 annexed Lower Lusatia to Bohemia and bought numerous estates in various parts of Germany. On the death in 1363 of Meinhard, duke of Upper Bavaria and count of Tirol, Upper Bavaria was claimed by the sons of the emperor Louis IV., and Tirol by Rudolph IV., duke of Austria. Both claims were admitted by Charles on the understanding that if these families died out both territories should pass to the house of Luxemburg. About the same time he was promised the succession to the margravate of Brandenburg, which he actually obtained for his son Wenceslas in 1373. He also gained a considerable portion of Silesian territory, partly by inheritance through his third wife, Anna, daughter of Henry II., duke of Schweidnitz. In 1365 Charles visited Pope Urban V. at Avignon and undertook to escort him to Rome; and on the same occasion was crowned king of Burgundy, or Arles, at Arles on June 4, 1365. During his later years the emperor took little part in German affairs beyond securing the election of his son Wenceslas as king of the Romans in 1376, and negotiating a peace between the Swabian league and some nobles in 1378. After dividing his lands between his three sons, he died on Nov. 29, 1378, at Prague, where he was buried.

Charles, who according to the emperor Maximilian I. was the step-father of the empire, but the father of Bohemia, brought the latter country to a high state of prosperity. In 1348 he founded the university of Prague, and afterwards made this city the seat of an archbishop. He was an accomplished diplomatist, possessed a penetrating intellect, and was capable of much trickery in order to gain his ends. He was superstitious and peace-loving, had few personal wants, and is described as a round-shouldered man of medium height, with black hair and beard, and sallow cheeks.

His autobiography, the "*Vita Caroli IV.*," which deals with events down to the year 1346, and various other documents relating to his life and times, are published in the *Fontes rerum Germanicarum*, Band I., edited by J. F. Böhmer (Leipzig, 1885). For other documents relating to the time see *Die Regesten des Kaiserreichs unter Kaiser Karl IV.*, edited by J. F. Böhmer and A. Huber (Innsbruck, 1889); *Acta Karoli IV. imperatoris inedita* (Innsbruck, 1891); E. Werunsky, *Excerpta ex registris Clementis VI. et Innocentii VI.* (Innsbruck, 1885). See also E. CHARLES V. (1500-1558), Roman emperor and (as Charles I.) king of Spain, was born in Ghent on Feb. 20, 1500. His parents were Philip of Burgundy and Joanna, third child of Ferdinand and Isabella. Philip died in 1506, and Charles succeeded to his Netherland possessions and the county of Burgundy (Franche Comté). His grandfather, the emperor Maximilian, as regent, appointed his daughter Margaret vice-regent, and under her strenuous guardianship Charles lived in the Netherlands until the estates declared him of age in 1515. In Castile, Ferdinand, king of Aragon, acted as regent for his daughter Joanna, whose intellect was already clouded. On Jan. 23, 1516, Ferdinand died. Charles's visit to Spain was delayed until the autumn of 1517, and only in 1518 was he formally recognized as king conjointly with his mother, firstly by the cortes of Castile and then by those of Aragon. Joanna lived to the very eve of her son's abdication, so that he was only for some months technically sole king of Spain. During this Spanish visit Maximilian died, and Charles succeeded to the inheritance of the Habsburgs, to which was shortly added the duchy of Württemberg. Maximilian had also intended that he should succeed as emperor. In spite of the formidable rivalry of Francis I. and the opposition of Pope Leo X., pecuniary corruption and national feeling combined to secure his election in 1519. Charles hurriedly left Spain, and after a visit to Henry VIII. and his aunt Catherine was crowned at Aix on Oct. 23, 1520.

The difficulty of Charles's reign consists in the complexity of interests caused by the unnatural aggregate of distinct territories and races. The Crown of Castile brought with it the two recently conquered kingdoms of Navarre and Granada, together with the new colonies in America and scattered possessions in northern Africa. That of Aragon comprised the three distinct States of Aragon, Valencia and Catalonia, and in addition the kingdoms of Naples, Sicily and Sardinia, each with a separate character and constitution of its own. No less than eight independent cortes or parliaments existed in this Spanish-Italian group, adding greatly to the intricacy of government. In the Netherland provinces again the tie was almost purely personal; there existed only the rudiments of a central administration and a common representative system, while the county of Burgundy had a history apart. Much the same was true of the Habsburg group of States, but Charles soon freed himself from direct responsibility for their government by making them over, together with Württemberg, to his brother Ferdinand. The empire entailed serious liabilities on its ruler without furnishing any reliable assets; only through the cumbrous machinery of the diet could Charles tap the military and financial resources of Germany. His problem here was complicated by the growth of Lutheranism, which he had to face at his very first diet in 1521. In addition to such administrative difficulties Charles had inherited a quarrel with France, to which the rivalry of Francis I. for the Empire gave a personal character. Almost equally formidable was the advance of Sultan Suleiman up the Danube, and the union of the Turkish naval power with that of the Barbary States of northern Africa. Against Lutheran Germany the Catholic emperor might hope to rely upon the pope, and against France on England. But the attitude of the popes was almost uniformly disagreeable, while from Henry VIII. and Edward VI. Charles met with more unpleasantness than favour.

The difficulty of Charles himself is also that of the historian and reader of his reign. It is probably more instructive to treat it according to the emperor's several problems than in strict chronological order. Yet an attempt to distinguish the several periods of his career may serve as a useful introduction. The two best dividing lines are, perhaps, the coronation as emperor at Bologna in 1530, and the peace of Crépy in 1544. Until his visit to Italy (1529) Charles remained in the background of the European stage, except for his momentous meeting with Luther

at the diet of Worms (1521). This meeting in itself forms a subdivision. Previously to this, during his nominal rule in the Netherlands, his visit to Spain and his candidature for the Empire, he seemed, as it was said, spell-bound under the ferule of his minister Chièvres. Almost every report represented him as colourless, reserved and weak. His dependence on his Flemish counsellors provoked the rising in Castile, the feebleness of his government the social war in Aragon. The religious question first gave him a living interest, and at this moment Chièvres died. Aleander, the papal nuncio at Worms, now recognized that public opinion had been wrong in its estimate of Charles. Never again was he under tutelage. The necessity, however, of residence in Spain prevented his taking a personal part in the great fight with Francis I. for Italy. He could claim no credit for the capture of his rival at Pavia. When his army sacked Rome and held Pope Clement VII. prisoner, he could not have known where his army was. And when later the French overran Naples, and all but deprived him of his hold on Italy, he had to instruct his generals that they must shift for themselves. The world had become afraid of him, but knew little of his character. In the second main division of his career Charles changed all this. No monarch until Napoleon was so widely seen in Europe and in Africa. At the head of his army Charles forced the Turks backwards down the Danube (1532). He personally conquered Tunis (1535), and was only prevented by "act of God" from winning Algiers (1541). The invasion of Provence in 1536 was headed by the emperor. In person he crushed the rebellion of Ghent (1540). In his last war with Francis (1542-44) he journeyed from Spain to the Netherlands, brought the rebellious duke of Cleves to his knees, and was within easy reach of Paris when he made the peace of Crépy (1544). In Germany, meanwhile, from the diet of Augsburg (1530) onwards, he had presided at the diets or conferences, which, as he hoped, would effect the reunion of the Church.

Peace with France and the Turk and a short spell of friendliness with Pope Paul III. enabled Charles at last to devote his whole energies to the healing of religious schism. Conciliation proving impossible, he led the army which received the submission of the Lutheran States, and then captured the elector of Saxony at Mühlberg, after which the other leader, Philip of Hesse, capitulated. The Armed Diet of 1548 was the high-water mark of Charles's power. Here, in defiance of the pope, he published the Interim which was meant to reconcile the Lutherans with the Church, and the so-called Reform which was to amend its abuses. During the next four years, owing to ill-health and loss of insight, his power was ebbing. In 1552 he was flying over the Brenner from Maurice of Saxony, a princeling whose fortunes he had made. Once again the old complications had arisen. His old enemy's son, Henry II., had attacked him indirectly in Piedmont and Parma, and then directly in Germany in alliance with Maurice. Once more the Turk was moving in the Danube and in the western Mediterranean. The humiliation of his flight gave Charles new spirit, and he once more led an army through Germany against the French, only to be checked by the duke of Guise's defence of Metz. Henceforth the waves of his fortune plashed to and fro until his abdication without much ostensible loss or gain.

Charles's Policy.—Charles had abundance of good sense, but little creative genius, and he was by nature conservative. Consequently he never sought to impose any new or common principles of administration on his several States. He took them as he found them, and at most, as in the Netherlands, improved upon what he found. So also in dealing with rival powers his policy may be called opportunist. He was indeed accused by his enemies of emulating Charlemagne, of aiming at universal empire. Historians have frequently repeated this charge. Charles himself in later life laughingly denied the imputation, and facts are in favour of his denial. When Francis I. was in his power he made no attempt to dismember France, in spite of his pledges to his allies Henry VIII. and the duke of Bourbon. He did, indeed, demand the duchy of Burgundy, because he believed this to have been unrighteously stolen by Louis XI. from his grandmother

when a helpless girl. The claim was not pressed, and at the height of his fortunes in 1548 he advised his son never to surrender it, but also never to make it a cause of war. When Clement VII. was his prisoner he was vehemently urged to overthrow the temporal power, to restore imperial dominion in Italy, at least to make the papacy harmless for the future. In reply he restored his enemy to the whole of his dominions, even reimposing him by force on the Florentine republic. To the end of his life his conscience was sensitive as to Ferdinand's expulsion of the house of Albret from Spanish Navarre, though this was essential to the safety of Spain. Though always at war he was essentially a lover of peace, and all his wars were virtually defensive. "Not greedy of territory," wrote Marcantonio Contarini in 1536, "but most greedy of peace and quiet." For peace he made sacrifices which angered his hot-headed brother Ferdinand. He would not aid in expelling the sultan's puppet Zapolya from Ferdinand's kingdom of Hungary, and he suffered the restoration of the ruffianly duke of Württemberg, to the grave prejudice of German Catholicism. In spite of his protests, Henry VIII. with impunity ill-treated his aunt Catherine, and the feeble Government of Edward VI. bullied his cousin Mary, who had been his fiancée. No serious efforts were made to restore his brother-in-law, Christian II., to the throne of Denmark, and he advised his son Philip to make friends with the usurper. After the defeat of the Lutheran Powers in 1547 he did not gain a palm's breadth of territory for himself. He resisted Ferdinand's claim for Württemberg, which the duke had deserved to forfeit; he disliked his acceptance of the voluntary surrender of the city of Constance; he would not have it said that he had gone to war for the benefit of the house of Habsburg.

On the other hand, Charles V.'s policy was not merely negative. He enlarged upon the old Habsburg practice of marriage as a means of alliance of influence. Previously to his election as emperor, his sister Isabella was married to Christian II. of Denmark, and the marriages of Mary and Ferdinand with the king of Hungary and his sister had been arranged. Before he was 20 Charles himself had been engaged some ten times with a view to political combinations. Naturally, therefore, he regarded his near relations as diplomatic assets. The federative system was equally familiar; Germany, the Netherlands, and even Spain, were in a measure federations. Combining these two principles, he would within his more immediate spheres of influence strengthen existing federations by intermarriage, while he hoped that the same means would convert the jarring Powers of Europe into a happy family. He made it a condition of the Treaty of Madrid (1526) that Francis I. should marry his sister Eleanor, Manuel of Portugal's widow, in the hope, not that she would be an ally or a spy within the enemy's camp, but an instrument of peace. His son's marriage with Mary Tudor would not only save the rubs with England, but give such absolute security to the Netherlands that France would shrink from war. The personal union of all the Iberian kingdoms under a single ruler had long been an aim of Spanish statecraft. So Charles had married his sister Eleanor, much against her will, to the old king Manuel, and then his sister Catherine to his successor. The empress was a Portuguese infanta, and Philip's first wife was another. It is thus small wonder that, within a quarter of a century of Charles's death, Philip became king of Portugal.

In the wars with Francis I. Italy was the stake. In spite of his success Charles for long made no direct conquests. He would convert the peninsula into a federation mainly matrimonial. Savoy, the important buffer state, was detached from France by the marriage of the somewhat feeble duke to Charles's capable and devoted sister-in-law, Beatrice of Portugal. Milan, conquered from France, was granted to Francesco Sforza, heir of the old dynasty, and even after his treason was restored to him. In the vain hope of offspring Charles sacrificed his niece, Christina of Denmark, to the valetudinarian duke. In the long negotiations for a Habsburg-Valois dynasty which followed Francesco's death, Charles was probably sincere. He insisted that his daughter or niece should marry the third rather than the second son of Francis I., in order, apart from other reasons, to run less risk of

the duchy falling under French dominion. The final investiture of Philip was forced upon him, and does not represent his saner policy. The Medici of Florence, the Gonzaga of Mantua, the papal house of Farnese, were all attached by Habsburg marriages. The republics of Genoa and Siena were drawn into the circle through the agency of their chief noble families, the Doria and Piccolomini; while Charles behaved with scrupulous moderation towards Venice in spite of her active hostility before and after the League of Cognac. Occasional acts of violence there were, such as the participation in the murder of Pierluigi Farnese, and the measures which provoked the rebellion of Siena. These were due to the difficulty of controlling the imperial agents from a distance, and in part to the faults of the victim prince and republic. On the whole, the loose federation of viceroyalties and principalities harmonized with Italian interests and traditions. The alternative was not Italian independence, but French domination. At any rate, Charles's structure was so durable that the French met with no real success in Italy until the 18th century.

Germany offered a fine field for a creative intellect, since the evils of her disintegration stood confessed. On the other hand, princes and towns were so jealous of an increase of central authority that Charles, at least until his victory over the League of Schmalkalden, had little effective power. Owing to his wars with French and Turks he was rarely in Germany, and his visits were very short. His problem was infinitely complicated by the union of Lutheranism and princely independence. He fell back on the old policy of Maximilian, and strove to create a party by personal alliances and intermarriage. In this he met with some success. The friendship of the electors of Brandenburg, whether Catholic or Protestant, was unbroken. In the war of Schmalkalden half the Protestant princes were on Charles's side or friendly neutrals. At the critical moment which preceded this, the lately rebellious duke of Cleves and the heir of Bavaria were secured through the agency of two of Ferdinand's invaluable daughters. The relations, indeed, between the two old enemies, Austria and Bavaria, were permanently improved. The elector palatine, whose love affairs with his sister Eleanor Charles as a boy had roughly broken, received in compensation a Danish niece. Her sister, widow of Francesco Sforza, was utilized to gain a hold upon the French dynasty which ruled Lorraine. More than once there were proposals for winning the hostile house of Saxony by matrimonial means. After his victory over the League of Schmalkalden, Charles perhaps had really a chance of making the imperial power a reality. But he lacked either courage or imagination, contenting himself with proposals for voluntary association on the lines of the defunct Swabian League, and dropping even these when public opinion was against them. Now, too, he made his great mistake in attempting to foist Philip upon the Empire as Ferdinand's successor. Gossip reported that Ferdinand himself was to be set aside, and careless historians have given currency to this. Such an idea was impossible. Charles wished Philip to succeed Ferdinand, while he ultimately conceded that Ferdinand's son Maximilian should follow Philip, and even in his lifetime exercise the practical power in Germany. This scheme irritated Ferdinand and his popular and ambitious son at the critical moment when it was essential that the Habsburgs should hold together against princely malcontents. Philip was imprudently introduced to Germany, which had also just received a foretaste of the unpleasant characteristics of Spanish troops. Yet the person rather than the policy was, perhaps, at fault. It was natural that the quasi-hereditary succession should revert to the elder line. France proved her recuperative power by the occupation of Savoy and of Metz, Toul and Verdun, the military keys of Lorraine. The separation of the Empire and Spain left two weakened Powers not always at accord, and neither of them permanently able to cope on equal terms with France. Nevertheless, this scheme did contribute in no small measure to the failure of Charles in Germany. The main cause was, of course, the religious schism, but his treatment of this requires separate consideration.

The characteristics of Charles's government, its mingled conservatism and adaptability, are best seen in Spain and the

Netherlands, with which he was in closer personal contact than with Italy and Germany. In Spain, when once he knew the country, he never repeated the mistakes which on his first visit caused the rising of the communes. The cortes of Castile were regularly summoned, and though he would allow no encroachment on the Crown's prerogatives, he was equally scrupulous in respecting their constitutional rights. Indirectly, Crown influence increased owing to the greater control which had gradually been exercised over the composition of the municipal councils, which often returned the deputies for the cortes. Charles was throughout nervous as to the power and wealth of the greater nobles. They rather than the Crown had conquered the communes, and in the past they rather than the towns had been the enemies of monarchy. In the cortes of 1538 Charles came into collision with the nobles as a class. They usually attended only on ceremonial occasions, since they were exempted from direct taxation, which was the main function of the cortes. Now, however, they were summoned because Charles was bent upon a scheme of indirect taxation which would have affected all classes. They offered an uncompromising opposition, and Charles somewhat angrily dismissed them, nor did he ever summon them again.

Charles was well served by his ministers, whom he very rarely changed. After the death of the Piedmontese Gattinara he relied mainly on Nicolas Perrenot de Granvella for Netherland and German affairs, and on Francisco de los Cobos for Spanish, while the younger Granvella was being trained. From 1520-55 these were the only ministers of high importance. Above all, Charles never had a court favourite, and the only women who exercised any influence were his natural advisers, his wife, his aunt Margaret and his sister Mary. In all these ladies he was peculiarly fortunate.

The reign of Charles was in America the age of conquest and organization. Upon his accession the settlements upon the mainland were insignificant; by 1556 conquest was practically complete, and civil and ecclesiastical government firmly established. Actual expansion was the work of great adventurers starting on their own impulse from the older colonies. To Charles fell the task of encouraging such ventures, of controlling the conquerors, of settling the relations between colonists and natives, which involved those between the colonists and the missionary colonial Church. He must arrest de-population, provide for the labour market, regulate oceanic trade, and check military preponderance by civil and ecclesiastical organization. In America Charles took an unceasing interest; he had a boundless belief in its possibilities, and a determination to safeguard the interests of the Crown. Cortes, Alvarado and the brothers Pizarro were brought into close personal communication with the emperor. If he bestowed on Cortes the confidence which the loyal conqueror deserved, he showed the sternest determination in crushing the rebellious and autonomous instincts of Almagro and the Pizarros. But for this, Peru and Chile must have become independent almost as soon as they were conquered. Throughout he strove to protect the natives, to prevent actual slavery, and the consequent raids upon the natives. If in many respects he failed, yet the organization of Spanish America and the survival of the native races were perhaps the most permanent results of his reign. It is a proof of the complexity of his interests that the march of the Turk upon Vienna and of the French on Naples delayed until the following reign the foundation of Spain's eastern empire. Charles carefully organized the expedition of Magellan, which sailed for the Moluccas and discovered the Philippines. Unfortunately, his straits for money in 1529 compelled him to mortgage to Portugal his disputed claim to the Moluccas, and the Philippines consequently dropped out of sight.

If in the administration of Spain Charles did little more than mark time, in the Netherlands advance was rapid. Of the seven northern provinces he added five, containing more than half the area of the later United Provinces. In the south he freed Flanders and Artois from French suzerainty, annexed Tournai and Cambrai, and closed the natural line of French advance through the great bishopric of Liège by a line of fortresses across its western frontier. Much was done to convert the aggregate of jar-

ring provinces into a harmonious unity by means of common principles of law and finance, and by the creation of a national army. While every province had its own assembly, there were at Charles's accession only the rudiments of estates-general for the Netherlands at large. At the close of the reign the common parliamentary system was in full swing, and was fast converting the loosely knit provinces into a State.

In the Netherlands Charles showed none of the jealousy with which he regarded the Spanish nobles. He encouraged the growth of large estates through primogeniture; he gave the nobles the provincial governorships, the great court offices, the command of the professional cavalry. In the Order of the Golden Fleece and the long established presence of the court at Brussels, he possessed advantages which he lacked in Spain. The nobility were utilized as a link between the court and the provinces. Very different was it with the Church. By far the greater part of the Netherlands fell under foreign sees, which were peculiarly liable to papal exactions and to the intrigues of rival Powers. Thus the usual conflict between civil and ecclesiastical jurisdiction was peculiarly acute. To remedy this dualism of authority and the consequent moral and religious abuses, Charles early designed the creation of a national diocesan system, and this was a cherished project throughout his life. The papacy unfortunately thwarted him, and the scheme, which under Charles would have been carried with national assent and created a national Church-system, took the appearance under Philip of alien domination. If in Germany Charles was emperor, he was in the Netherlands territorial prince, and thus his interests might easily be at disaccord with those of the Empire. Consequently, just as he had shaken off French suzerainty from Flanders and Artois, so he loosened the tie of the other provinces to Germany. In 1548 they were declared free and sovereign principalities not subject to imperial laws, and all the territories were incorporated in the Burgundian circle. It was, indeed, agreed that they should contribute to imperial taxation, and in return receive imperial protection. But this soon became a dead letter, and the Netherlands were really severed from the Empire, save for the nominal feudal tie in the case of some provinces.

Charles's Religious Aims.—Charles V. is, in the eyes of many, the very picture of a Catholic zealot. Popular opinion is probably based in the main upon the letters written from Yuste in 1558, when two hot-beds of heresy had been discovered in Spain herself, and on the contemporary codicil to his will. Charles was not then the responsible authority. There is a long step between a violent letter and a violent act. Few men would care to have their lives judged by letters written in the last extremities of gout. Less pardonable was the earlier persecution of the Valencian Moriscos in 1525-26. The edict of persecution was cruel and unnecessary, and all expert opinion in Valencia was against it. It was not, however, actually enforced until after the victory of Pavia. It seems likely that Charles in a fit of religious exaltation regarded the persecution as a sacrificial thank-offering for his miraculous preservation. Henceforth the reign was marked by extreme leniency. Spain enjoyed a long lull in the activity of her Inquisition. At Naples in 1547 a rumour that the Spanish Inquisition was to be introduced to check the growth of heresy in influential quarters produced a dangerous revolt. The briefs were, however, issued by Paul III., no friend of Charles, and when a Neapolitan deputation visited the emperor he disclaimed any intention of making innovations. Of a different type to all the above was the persecution in the Netherlands. Here it was deliberate, chronic, and on an ascending scale. In the Netherlands the heretics were his immediate subjects, and as in every other State, Catholic or Lutheran, they must conform to their prince's religion. But there was more than this. After the suppression of the German peasant revolt in 1525 many of the refugees found shelter in the teeming Netherland cities, and heresy took the form, not of Lutheranism, but of Anabaptism, which was believed to be perilous to society and the State. The Government put down Anabaptism, as a modern Government might stamp out anarchism. The edicts were, indeed, directed against heresy in general, and were as harsh as they could be—at least on paper. Yet when

Charles was assured that they were embarrassing foreign trade he let it be understood that they should not affect the foreign mercantile communities. Prudential considerations proved frequently a drag upon religious zeal.

The relations of Charles to heresy must be judged in the main by his treatment of German Lutheranism. Here he had to deal with organized Churches protected by their princes, supported by revenues filched from his own Church and stiffened by formulae as rigid as those of Catholicism. The length and stubbornness of the conflict will serve to show that Charles's religious conservatism had a measure of elasticity, that he was not a bigot and nothing more. The two more obvious courses towards the restoration of Catholic unity were force and reconciliation, in other words, a religious war or a general council. Neither of these was a simple remedy. The latter was impossible without papal concurrence, inoperative without the assistance of the European Powers, and merely irritant without the adhesion of the Lutherans. It was most improbable that the papacy, the Powers and the Lutherans would combine in a measure so palpably advantageous to the emperor. Force was hopeless save in the absence of war with France and the Turk, and of papal hostility in Italian territorial politics. Charles must obtain subsidies from ecclesiastical sources, and the support of all German Catholics, especially of the traditional rival, Bavaria. Even so the Protestants would probably be the stronger, and therefore they must be divided by utilizing any religious split, any class distinction, any personal or traditional dislikes, or else by bribery. Force and reconciliation seeming equally difficult; could an alternative be found in toleration? The experiment might take the form either of individual toleration, or of toleration for the Lutheran States. The former would be equally objectionable to Lutheran and Catholic princes as loosening their grip upon their subjects. Territorial toleration might seem equally obnoxious to the emperor, for its recognition would strengthen the anti-imperial particularism so closely associated with Lutheranism. If Charles could find no permanent specific, he must apply a provisional palliative. It was absolutely necessary to patch, if not to cure, because Germany must be pulled together to resist French and Turks. Such palliatives were two—suspension and comprehension. Suspension deferred the execution of penalties incurred by heresy, either for a term of years, or until a council should decide. Thus it recognized the divorce of the two religions, but limited it by time. Comprehension instead of recognizing the divorce would strive to conceal the breach. It was a domestic remedy, German and national, not European and papal. To become permanent it must receive the sanction of pope and council, for the Roman emperor could not set up a Church of Germany. Yet the formula adopted might conceivably be found to fall within the four corners of the faith, and so obviate the necessity alike of force or council. Such were the conditions of the emperor's task, and such the methods which he actually pursued. He would advance now on one line, now on another, now on two or three concurrently, but he never definitely abandoned any. This fusion of obstinacy and versatility was a marked feature of his character.

Suspension was of course often accidental and involuntary. The two chief stages of Lutheran growth naturally corresponded with the periods, each of nine years, when Charles was absent. Deliberate suspension was usually a consequence of the failure of comprehension. Thus at Augsburg in 1530 the wide gulf between the Lutheran confession and the Catholic confutation led to the definite suspensive treaty granted to the Lutherans at Nuremberg (1532). Charles dared not employ the alternative of force, because he needed their aid for the Turkish war. In 1541, after a series of religious conferences, he personally presented a compromise in the so-called Book of Regensburg, which was rejected by both parties. He then proposed that the articles agreed upon should be compulsory, while on others toleration should be exercised until a national council should decide. Never before nor after did he go so far upon the path of toleration, or so nearly accept a national settlement. He was then burning to set sail for Algiers. His last formal suspensive measure was that of Spires (Speyer) in 1544, when he was marching against Francis.

He promised a free and general council to be held in Germany, and, as a preparation, a national religious congress. The Lutherans were privately assured that a measure of comprehension should be concluded with or without papal approval. Meanwhile all edicts against heresy were suspended. No wonder that Charles afterwards confessed that he could scarcely reconcile these concessions with his conscience, but he won Lutheran aid for his campaign. The peace of Cr py gave all the conditions required for the employment of force. He had peace with French and Turk, he won the active support of the pope, he had deeply divided the Lutherans and reconciled Bavaria. Finding that the Lutherans would not accept the council summoned by the pope to Trent, he resorted to force, and force succeeded. At the Armed Diet of 1548 reunion seemed within reach. But Paul III. in direct opposition to Charles's wish had withdrawn the council from Trent to Bologna. Charles could not force Lutherans to submit to a council which he did not himself recognize, and he could not bring himself to national schism. Thus, falling back upon his old palliatives, he issued the Interim and the accompanying Reform of the Clergy, pending a final settlement by a satisfactory general council. These measures pleased neither party, and Charles at the very height of his power had failed. He was conscious of failure, and made few attempts even to enforce the Interim. Henceforward political complications gathered round him anew. The only remedy was toleration in some form, independent of the papacy and limitless in time. To this Charles could never assent. His ideal was shattered, but it was a great ideal, and the patience, the moderation, even at times the adroitness with which he had striven towards it, proved him to be no bigot.

Abdication and Death.—The idea of abdication had long been present with Charles, and in 1555 he acted upon it. To Ferdinand he gave his full authority as emperor, although at his brother's earnest request formal abdication was delayed until 1558. In the Hall of the Golden Fleece at Brussels on Oct. 25, 1555, he formally resigned to Philip the sovereignty of his beloved Netherlands. Turning from his son to the representatives of the estates he said: "Gentlemen, you must not be astonished if, old and feeble as I am in all my members, and also from the love I bear you, I shed some tears." In the Netherlands at least the love was reciprocal, and tears were infectious among the thousand deputies who listened to their sovereign's last speech. On Jan. 16, 1556, Charles resigned his Spanish kingdoms and that of Sicily, and shortly afterwards his county of Burgundy. On Sept. 17 he sailed from Flushing on the last of his many voyages, an English fleet from Portland bearing him company down the channel. In Feb. 1557 he was installed in the home which he had chosen at Yuste in Estremadura.

The excellent books which have been written upon the emperor's retirement have inspired an interest out of all proportion to its real significance. His little house was attached to the monastery, but was not within it. He was neither an ascetic nor a recluse. Gastronomic indiscretions still entailed their inevitable penalties. Society was not confined to interchange of civilities with the brethren. His relations, his chief friends, his official historians, all found their way to Yuste. Couriers brought news of Philip's war and peace with Pope Paul IV., of the victories of Saint Quentin and Gravelines, of the French capture of Calais, of the danger of Oran. As head of the family he intervened in the delicate relations with the closely allied house of Portugal; he even negotiated with the house of Navarre for reparation for the wrong done by his grandfather Ferdinand, which appeared to weigh upon his conscience. Above all he was shocked by the discovery that Spain, his own court, and his very chapel were infected with heresy. His violent letters to his son and daughter recommending immediate persecution, his profession of regret at having kept his word when Luther was in his power, have weighed too heavily on his reputation. The feverish phrases of religious exaltation due to broken health and unnatural retirement cannot balance the deliberate humanity and honour of wholesome manhood. Apart from such occasional moments of excitement, the emperor's last years passed tranquilly enough. At first he would shoot pigeons in the monastery woods, and till

his last illness tended his garden and his animal pets, or watched the operations of Torriani, maker of clocks and mechanical toys. After an illness of three weeks the call came in the early hours of the Feast of St. Matthew, who, as his chaplain said, had for Christ's sake forsaken wealth even as Charles had forsaken empire. The dying man clasped his wife's crucifix to his breast till his fingers lost their hold. The archbishop held it before his eyes, and with the cry of "*Ay Jesus!*" died, in the words of his faithful squire, D. Luis de Quijada, "the chief of men that had ever been or would ever be." Posterity need not agree, but no great man can boast a more honest panegyric.

In character Charles stands high among contemporary princes. It consists of pairs of contrasts, but the better side is usually stronger than the worse. Steadfast honesty of purpose was occasionally warped by self-interest, or rather he was apt to think that his own course must needs be that of righteousness. Self-control would give way, but very rarely, to squalls of passion. Obstinance and irresolution were fairly balanced, the former generally bearing upon ends, the latter upon means. His own ideals were constant, but he could gradually assimilate the views of others, and could bend to argument and circumstance; yet even here he had a habit of harking back to earlier schemes which he had seemed to have definitely abandoned. As a soldier he must rank very high. It was said that his being emperor lost to Spain the best light horseman of her army. At every crisis he was admirably cool, setting a truly royal example to his men. His mettle was displayed when he was attacked on the burning sands of Tunis, when his troops were driven in panic from Algiers, when in spite of physical suffering he forded the Elbe at M hlberg, and when he was bombarded by the vastly superior Lutheran artillery under the walls of Ingolstadt. When blamed for exposing himself on this last occasion, "I could not help it," he apologized; "we were short of hands, I could not set a bad example." Nevertheless he was by nature timid. Just before this very action he had a fit of trembling, and he was afraid of mice and spiders. The force of his example was not confined to the field. Melancthon wrote from Augsburg in 1530 that he was a model of continence, temperance and moderation, that the old domestic discipline was now only preserved in the imperial household. He tenderly loved his wife, whom he had married for pecuniary and diplomatic reasons. Of his two well-known illegitimate children, Margaret was born before he married, and Don John long after his wife's death, but he felt this latter to be a child of shame. His sobriety was frequently contrasted with the universal drunkenness of the German and Flemish nobles, which he earnestly condemned. But on his appetite he could place no control, in spite of the ruinous effects of his gluttony upon his health. In dress, in his household, and in his stable he was simple and economical. He loved children, flowers, animals and birds. Professional jesters amused him, and he was not above a joke himself. Maps and mechanical inventions greatly interested him, and in later life he became fond of reading. He takes his place indeed among authors, for he dictated the commentaries on his own career. Of music he possessed a really fine knowledge, and his high appreciation of Titian proves the purity of his feeling for art. The little collection of books and pictures which he carried to Yuste is an index of his tastes. Charles was undeniably plain. He confessed that he was by nature ugly, but that as artists usually painted him uglier than he was strangers on seeing him were agreeably disappointed. The protruding lower jaw and the thin pale face were redeemed by the fine open brow and the bright speaking eyes. He was, moreover, well made, and in youth had an incomparable leg. Above all no man could doubt his dignity; Charles was every inch an emperor. (E. A.)

Rosi, *Il Primato di Carlo V.* (1925).

CHARLES VI. (1685-1740), Roman emperor, was born on Oct. 1, 1685, at Vienna. He was the second son of the emperor Leopold I. by his third marriage with Eleanore, daughter of Philip William of Neuburg, elector palatine of the Rhine. When the Spanish branch of the house of Habsburg became extinct in 1700, he was put forward as the lawful heir in opposition to Philip V., the Bourbon to whom the Spanish dominions had been left by the will of Charles II. of Spain. He was proclaimed at Vienna on Sept. 19, 1703, and made his way to Spain by the Low Countries, England and Lisbon, remaining in Spain till 1711, mostly in Catalonia, where the Habsburg party was strong. Although he had a certain tenacity of purpose he displayed none of the qualities required in a prince who had to gain his throne by the sword (See SPANISH SUCCESSION, WAR OF). In 1708 he was married at Barcelona to Elizabeth Christina of Brunswick-Wolfenbüttel (1691-1750), a Lutheran princess who was persuaded to accept Roman Catholicism. On the death of his elder brother Joseph I. on April 17, 1711, Charles inherited the hereditary possessions of the house of Habsburg and their claims on the Empire. The death of Joseph without male issue had been foreseen, and Charles had at one time been prepared to give up Spain and the Indies on condition that he was allowed to retain Naples, Sicily and the Milanese. But when the case arose his natural obstinacy led him to declare that he would not think of surrendering any of the rights of his family. It was with great difficulty that he was persuaded to leave Spain, months after the death of his brother (on Sept. 27, 1711). Only the emphatic refusal of the European powers to tolerate the reconstruction of the empire of Charles V. forced him to give a sullen submission to necessity. He abandoned Spain and was crowned emperor in December 1711, but for a long time he would not recognize Philip V. Charles showed an enlightened, though not always successful, interest in the commercial prosperity of his subjects, but from the date of his return to Germany till his death his ruling passion was to secure his inheritance against dismemberment. As early as 1713 he had begun to prepare the "Pragmatic Sanction" which was to regulate the succession, and it became the object of his policy to obtain the recognition of his daughter Maria Theresa as his heir. His last days were embittered by a disastrous war with Turkey, in which he lost almost all he had gained by the peace of Passarowitz. He died at Vienna on Oct. 20, 1740, and with him expired the male line of his house.

For the personal character of Charles VI. see A. von Arneth, *Geschichte Maria Theresias* (Vienna, 1863-79). Dr. Franz Krones, R. v. Marchland, *Grundriss der österreichischen Geschichte* (Vienna, 1882), gives a very copious bibliography. See also J. Ziekursch, *Die Kaiserwahl Karls VI.* (1902).

CHARLES VII. (1697-1745), Roman emperor, known also as Charles Albert, elector of Bavaria, was the son of the elector Maximilian Emanuel and his second wife, Theresa Cunigunda, daughter of John Sobieski, king of Poland. He was born on Aug. 6, 1697. His father having taken the side of Louis XIV. of France in the War of the Spanish Succession (*q.v.*), Bavaria was occupied by the allies. Charles and his brother Clement, afterwards archbishop of Cologne, were carried prisoners to Vienna, and were educated by the Jesuits under the name of the counts of Wittelsbach. When his father was restored to his electorate Charles was released, and in 1717 he led the Bavarian contingent of the imperial army which served under Prince Eugene against the Turks, and is said to have distinguished himself at Belgrade. On Sept. 25, 1722, he was betrothed to Maria Amelia, the younger of the two orphan daughters of the emperor Joseph I. Her uncle

Charles VI. insisted that the Bavarian house should recognize the Pragmatic Sanction which established his daughter Maria Theresa as heir of the Habsburg dominions. They did so, but with secret protests and mental reservations of their rights, which were designed to render the recognition valueless. The electors of Bavaria had claims on the possessions of the Habsburgs under the will of the emperor Ferdinand I., who died in 1564.

Charles succeeded his father on Feb. 26, 1726. His policy was to keep on good terms with the emperor while slipping out of his obligation to accept the Pragmatic Sanction and intriguing to secure French support for his claims whenever Charles VI. should die. These claims were advanced immediately after the death of Charles VI. on Oct. 20, 1740. Charles Albert now entered into the league against Maria Theresa, to the great misfortune of himself and his subjects. By the help of her enemies he was elected emperor in opposition to her husband Francis, grand duke of Tuscany, on Jan. 24, 1742, under the title of Charles VII. and was crowned at Frankfurt-am-Main on Feb. 12. But as his army had been neglected, he was utterly unable to resist the Austrian troops. While he was being crowned his hereditary dominions in Bavaria were being overrun. During the War of the Austrian Succession (*q.v.*) he was a mere puppet in the hands of the anti-Austrian coalition, and was often in want of mere necessities. In the changes of the war he was able to re-enter his capital, Munich, in 1743, but had immediately afterwards to take flight again. He was restored by Frederick the Great in Oct. 1744, but died worn out at Munich on Jan. 20, 1745.

See A. von Arneth, *Geschichte Maria Theresias* (Vienna, 1863-79), and P. T. Heigel, *Der österreichische Erbfolgestreit und die Kaiserwahl Karls VII.* (Munich, 1877).

CHARLES I. (1887-1922), emperor of Austria and king of Hungary, born Aug. 17, 1887, in Persenbeug, in Lower Austria, was the son of the archduke Otto (1863-1906), and Princess Maria Josepha of Saxony (b. 1867). The death of his father in 1906 and the renunciation by his uncle, the archduke Francis Ferdinand, on his marriage with the countess Chotek (1900) of any right of succession for the children of this union, made him heir-presumptive to his grandfather, the emperor, Francis Joseph. In Oct. 1911 he married the princess Zita of Bourbon-Parma. Of this marriage there were several sons and daughters, the eldest of whom, Otto, was born in 1912. Charles' relations with the emperor were not intimate, and those with Francis Ferdinand not cordial. After the death of Francis Ferdinand the old emperor took steps to initiate him in affairs of State; but these studies were interrupted almost immediately by the outbreak of the World War. After a period at headquarters at Teschen, Charles commanded the 20th Corps in the offensive of 1916 against Italy, later commanding an army on the eastern front.

Charles as Emperor.—On Nov. 21, 1916, he succeeded to the throne, at a period of extreme difficulty, which he hoped to meet by making a complete change in the leading military and political posts in the monarchy. The changes, however, usually proved unfortunate. Charles himself was an amiable man of excellent intentions, but his abilities were mediocre and his preparatory training inadequate. He lacked calmness and endurance, and was prone to headlong, precipitate actions. He was powerfully influenced by his immediate entourage—his wife and mother-in-law—while distrusting all other advisers. But he was most bitterly—and justly—reproached for insincerity. Not merely his enemies, but his allies, particularly German statesmen and the emperor William, soon felt that they could not trust his word; a sentiment shared by the peoples of the Danubian monarchy.

On Charles' accession the Constitution in Austria was still suspended. In May 1917 he summoned parliament once more, but the concessions Charles now made to the Slavonic nationalities remained fruitless, merely alienating the majority of the German Austrians, while his concessions to the Magyars in Hungary similarly irritated the conservatives of Vienna and the non-Magyars of Hungary, without checking the separatist movement. He was equally unfortunate in his peace proposals. While refusing the idea of a separate peace for Austria, he endeavoured to persuade

Germany to buy a general peace by territorial concessions in the west. But the negotiations opened by Count Czernin only bred ill-will, which culminated on the publication of the so-called "Sixtus letter" of March 24, 1917. Charles' belated effort to convert Austria into a Federal State on national lines (Oct. 16, 1918) was rendered futile by the failure to apply it to Hungary; and Charles was obliged to renounce participation in the Government of Austria on Nov. 11, 1918, and of Hungary two days later. (See HABSBURGS.) After the proclamation of the Austrian republic, Charles retired to his castle of Eckartsau; thence he went, the Austrian Government having demanded his departure, on March 24, 1919, to Switzerland, where he stayed first at Schloss Gstaad and later at Prangins. His attempt at the end of March 1921 to secure his restoration as king of Hungary failed owing to the attitude of the regent, Horthy, and other leading Hungarians and the unanimous opposition of the Succession States and the Entente.

Charles returned to Switzerland, where a provisional prolongation of his residence was accorded him subject to certain conditions. In Oct. 1921, however, he made a surprise air flight with his wife from Switzerland to the Burgenland, where he was joined by a small force of armed Royalists, at whose head he marched on Budapest. But the Allied Powers, as well as the "Little Entente," made it clear that a *coup d'état* would not be tolerated, and there was a strong rally at Budapest to the side of the Horthy Government. The Royalists were met near Budapest and defeated, Charles and Zita being themselves arrested at Tihany.

On instructions from the Powers, the definite deposition of Charles and renunciation of his claims to the throne were insisted upon, and he and his wife were handed over to the custody of the Allies for internment. Refused the right of asylum by Switzerland, on the ground that he had not adhered to the conditions agreed upon, and accorded a reception by Portugal alone, he was conveyed upon the English ship "Cardiff" to Funchal, Madeira. Here he lived in straitened circumstances until his death on April 1, 1922.

CHARLES I. (1600–1649), king of Great Britain and Ireland, second son of James I. and Anne of Denmark, was born at Dunfermline on Nov. 19, 1600. At his baptism he was created duke of Albany, and on Jan. 16, 1605 duke of York. In 1612, by the death of his elder brother Henry, he became heir-apparent, and was created prince of Wales on Nov. 3, 1616. In 1620 he took up warmly the cause of his sister the queen of Bohemia, and in 1621 he defended Bacon, using his influence to prevent the chancellor's degradation from the peerage. The prince's marriage with the Infanta Maria, daughter of Philip III. of Spain, had been for some time the subject of negotiation, James desiring to obtain through Spanish support the restitution of his son-in-law, Frederick, to the Palatinate; and in 1623 Charles was persuaded by Buckingham, who now obtained a complete ascendancy over him in opposition to wiser advisers and the king's own wishes, to make a secret expedition himself to Spain, put an end to all formalities, and bring him his mistress himself; "a gallant and brave thing for his Highness." "Steenie" and "Baby Charles," as James called them, started on Feb. 17, arriving at Paris on the 21st and at Madrid on March 7, where they assumed the unromantic names of Mr. Smith and Mr. Brown. They found the Spanish court by no means enthusiastic for the marriage and the princess herself averse. The prince's immediate conversion was expected, and a complete religious tolerance for the Roman Catholics in England demanded. James engaged to allow the infanta the right of public worship and to use his influence to modify the law, but Charles himself went much further. He promised the alteration of the penal laws within three years, conceded the education of the children to the mother till the age of 12, and undertook to listen to the infanta's priests in matters of religion, signing the marriage contract on July 25, 1623. The Spanish, however, did not trust to words, and Charles was informed that his wife could only follow him to England

when these promises were executed. Moreover, they had no intention whatever of aiding the Protestant Frederick. Meanwhile Buckingham, incensed at the failure of the expedition, had quarrelled with the grandees, and Charles left Madrid, landing at Portsmouth on Oct. 5, to the joy of the people, to whom the proposed alliance was odious. He now with Buckingham urged James to make war on Spain, and in Dec. 1624 signed a marriage treaty with Henrietta Maria, daughter of Henry IV. of France. In April Charles had declared solemnly to the parliament that in case of his marriage to a Roman Catholic princess no concessions should be granted to recusants, but these were in Sept. 1624 deliberately promised by James and Charles in a secret article, the first instance of the duplicity and deception practised by Charles in dealing with the parliament and the nation. The French on their side promised to assist in Mansfeld's expedition for the recovery of the Palatinate, but Louis in October refused to allow the men to pass through France; and the army, without pay or provisions, dwindled away in Holland to nothing.

On March 27, 1625, Charles I. succeeded to the throne by the death of his father, and on May 1 he was married by proxy to Henrietta Maria. He received her at Canterbury on June 13, and on the 18th his first parliament assembled. On the day of his marriage, Charles had given directions that the prosecutions of the Roman Catholics should cease, but he now declared his intention of enforcing the laws against them, and demanded subsidies for carrying on the war against Spain. The Commons, however, responded coldly. Charles had lent ships to Louis XIII. to be used against the Protestants at La Rochelle, and the Commons were not aware of the subtleties and fictitious delays intended to prevent their employment. The Protestant feelings of the Commons were also aroused by the king's support of the royal chaplain, Richard Montagu, who had repudiated Calvinistic doctrine. They only voted small sums, and sent up a petition on the state of religion; also reflecting upon Buckingham, whom they deemed responsible for the failure of Mansfeld's expedition, at the same time demanding counsellors in whom they could trust. Parliament was accordingly dissolved by Charles on Aug. 12. He hoped that greater success abroad would persuade the Commons to be more generous. On Sept. 8, 1625, he made the treaty of Southampton with the Dutch against Spain, and sent an expedition to Cadiz under Sir Edward Cecil, which, however, was a failure. In order to make himself independent of parliament he attempted to raise money on the crown jewels in Holland, and to diminish the opposition in the Commons he excluded the chief leaders by appointing them sheriffs. When the second parliament met, however, on Feb. 6, 1626, the opposition, led by Sir John Eliot, was more determined than before, and their attack was concentrated upon Buckingham. On March 29, Charles, calling the Commons into his presence, accused them of leading him into the war and of taking advantage of his difficulties to "make their own game." "I pray you not to be deceived," he said, "it is not a parliamentary way, nor 'tis not a way to deal with a king. Remember that parliaments are altogether in my power for their calling, sitting, and dissolution; therefore as I find the fruits of them good or evil, they are to continue or not to be." Charles, however, was worsted in several collisions with the two houses, with a consequent loss of influence. He was obliged by the peers to set at liberty Thomas Howard, earl of Arundel, whom he had put into the Tower; and to send a summons to the earl of Bristol, whom he had attempted to exclude from parliament, while the Commons compelled him, with a threat of doing no business, to liberate Eliot and Digges, the managers of Buckingham's impeachment, whom he had imprisoned. Finally in June the Commons answered Charles's demand for money by a remonstrance asking for Buckingham's dismissal, which they decided must precede the grant of supply. They claimed responsible ministers, while Charles considered himself the executive and the sole and unfettered judge of the necessities of the State. Accordingly on the 15th Charles dissolved the parliament.

The king was now in great need of money. He was at war with Spain and had promised to pay £30,000 a month to Christian

IV. of Denmark in support of the Protestant campaign in Germany. To these necessities was now added a war with France, Charles had never kept his promise concerning the recusants; disputes arose in consequence with his wife, and on July 31, 1626, he ordered all her French attendants to be expelled from Whitehall and sent back to France. At the same time several French ships carrying contraband goods to the Spanish Netherlands, were seized by English warships. On June 27, 1627, Buckingham with a large expedition sailed to the Isle of Ré to relieve La Rochelle, then besieged by the forces of Louis XIII. Though the success of the French Protestants was an object much desired in England, Buckingham's unpopularity prevented support being given to the expedition, and the duke returned to Plymouth on Nov. 11 completely defeated. Meanwhile Charles had endeavoured to get the money refused to him by parliament by means of a forced loan, dismissing Chief Justice Crewe for declining to support its legality, and imprisoning several of the leaders of the opposition for refusing to subscribe to it. These summary measures, however, only brought a small sum into the treasury. On Jan. 2, 1628, Charles ordered the release of all the persons imprisoned, and on March 17 summoned his third parliament.

Instead of relieving the king's necessities the Commons immediately proceeded to discuss the constitutional position and to formulate the Petition of Right, forbidding taxation without consent of parliament, arbitrary and illegal imprisonment, compulsory billeting in private houses, and martial law. Charles, on May 1, first demanded that they should "rest on his royal word and promise." He obtained an opinion from the judges that the acceptance of the petition would not absolutely preclude in certain cases imprisonments without showing cause, and after a futile endeavour to avoid an acceptance by returning an ambiguous answer which only exasperated the Commons, he gave his consent on June 7, in the full and usual form. Charles now obtained his subsidies, but no real settlement was reached, and his relations with the parliament remained as unfriendly as before. They proceeded to remonstrate against his government and against his support of Buckingham, and denied his right to tonnage and poundage. Accordingly, on June 26, they were prorogued. New disasters befell Charles, in the assassination of Buckingham, and in the failure of the fresh expedition sent to Ré. In Jan. 1629 the parliament reassembled, irritated by the exaction of the duties and seizure of goods during the interval, and suspicious of "innovations in religion," the king having forbidden the clergy to continue the controversy concerning Calvinistic and Arminian doctrines, the latter of which the parliament desired to suppress. While they were discussing these matters, on March 2, 1629, the king ordered them to adjourn, but amidst a scene of great excitement the speaker, Sir John Finch, was held down in his chair and the doors were locked, whilst resolutions against innovations in religion and declaring those who levied or paid tonnage and poundage enemies to their country were passed. Parliament was immediately dissolved, and Charles imprisoned nine members, leaders of the opposition, Eliot, Holles, Strode, Selden, Valentine, Coryton, Heyman, Hobart and Long. Eliot, the most formidable of his opponents, died in the Tower of consumption after long years of close and unhealthy confinement, Charles even refusing to surrender his corpse to his family.

For 11 years Charles ruled without parliaments and with some success. There seemed no reason to think that "that noise," to use Laud's expression concerning parliaments, would ever be heard again by those then living. A revenue of about £618,000 was obtained by enforcing the payment of tonnage and poundage, and—while avoiding the taxes, loans, and benevolences forbidden by the petition of right—by monopolies, fines for knighthood, and for pretended encroachments on the royal domains and forests, which enabled the king to meet expenditure at home. In Ireland, Charles, in order to get money, had granted the Graces in 1628, conceding security of titles of more than 60 years' standing, and a more moderate oath of allegiance for the Roman Catholics, together with the renunciation of the shilling fine for non-attend-

ance at church. He continued, however, to make various attempts to get estates into his possession on the pretext of invalid title, and on May 12, 1635, the City of London estates were sequestered. Charles here destroyed one of the most valuable settlements in Ireland founded by James I. in the interests of national defence, and at the same time extinguished the historic loyalty of the city of London, which henceforth steadily favoured the parliamentary cause. In 1633 Wentworth had been sent to Ireland to establish a mediaeval monarchy and get money, and his success in organization seemed great enough to justify the attempt to extend the system to England. Charles at the same time restricted his foreign policy to scarcely more than a wish for the recovery of the Palatinate, to further which he engaged in a series of numerous and mutually destructive negotiations with Gustavus Adolphus and with Spain, finally making peace with Spain on Nov. 5, 1630, an agreement which was followed on Jan. 2, 1631, by a further secret treaty, the two kings binding themselves to make war on the Dutch and partition their territories. A notable feature of this agreement was that while in Charles's portion Roman Catholicism was to be tolerated, there was no guarantee for the security of Protestantism in the territory to be ceded to Spain.

In 1634 Charles levied ship-money from the seaport towns for the increase of the navy, and in 1635 the tax was extended to the inland counties, which aroused considerable opposition. In Feb. 1637 Charles obtained an opinion in favour of his claims from the judges, and in 1638 the great Hampden case was decided in his favour. The apparent success, however, of Charles was imperilled by the general and growing resentment aroused by his exactions and whole policy, and this again was small compared with the fears excited by the king's attitude towards religion and Protestantism. He supported zealously Laud's rigid Anglican orthodoxy, his compulsory introduction of unwelcome ritual, and his narrow, intolerant and despotic policy, which was marked by several savage prosecutions and sentences in the Star Chamber, drove numbers of moderate Protestants out of the Church into Presbyterianism, and created an intense feeling of hostility to the Government throughout the country. Charles further increased the popular fears on the subject of religion by his welcome given to Panzani, the pope's agent, in 1634, who endeavoured unsuccessfully to reconcile the two churches, and afterwards to George Conn, papal agent at the court of Henrietta Maria, while the favour shown by the king to these was contrasted with the severe sentences passed upon the Puritans.

The same imprudent neglect of the national sentiment was pursued in Scotland. Charles had already made powerful enemies there by a declaration announcing the arbitrary revocation of former church estates to the crown. On June 18, 1633, he was crowned at Edinburgh with full Anglican ceremonial, which lost him the hearts of numbers of his Scottish subjects and aroused hostility to his government in parliament. After his return to England, he gave further offence by ordering the use of the surplice, by his appointment of Archbishop Spottiswoode as chancellor of Scotland, and by introducing other bishops into the privy council. In 1636 the new *Book of Canons* was issued by the king's authority, ordering the communion table to be placed at the east end, enjoining confession, and declaring excommunicate any who should presume to attack the new prayer-book. The latter was ordered to be used on Oct. 18, 1636, but it did not arrive in Scotland till May 1637. It was intensely disliked both as "popish" and as English. A riot followed its first use in St. Giles' cathedral on July 23, and Charles's order to enforce it on Sept. 10 was met by fresh disturbances and by the establishment of the "Tables," national committees which now became the real though informal government of Scotland. In 1638 the national covenant was drawn up, binding those that signed it to defend their religion to the death, and was taken by large numbers with enthusiasm all over the country. Charles now drew back, promised to enforce the canons and prayer-book only in a "fair and legal way," and sent the marquis of Hamilton as a mediator. The latter, however, a weak and incapable man, desirous of popularity with all parties, and unfaithful to the king's interests,

yielded everything, without obtaining the return of Charles's subjects to their allegiance. The assembly met at Glasgow on Nov. 21, and in spite of Hamilton's opposition immediately proceeded to judge the bishops. On the 28th Hamilton dissolved it, but it continued to sit, deposed the bishops and re-established Presbyterianism. The rebellion had now begun and an appeal to arms alone could decide the quarrel between Charles and his subjects. On May 28, 1639, he arrived at Berwick with a small and ill-trained force, thus beginning what is known as the first Bishops' War; but being confronted by the Scottish army at Duns Law, he was compelled to sign the treaty of Berwick on June 18, which provided for the disbandment of both armies and the restitution to the king of royal castles, referring all questions to a general assembly and a parliament. When the assembly met it abolished episcopacy, but Charles, who on Aug. 3, had returned to Whitehall, refused his consent to this and other measures proposed by the Scottish parliament. His extreme financial necessities, and the prospect of renewed hostilities with the Scots, now moved Charles, at the instigation of Strafford, who in September had left Ireland to become the king's chief adviser, to turn again to parliament for assistance as the last resource, and on April 13, 1640, the Short Parliament assembled. But on its discussing grievances before granting supplies and finally refusing subsidies till peace was made with the Scots, it was dissolved on May 5. Charles returned once more to measures of repression, and on the 10th imprisoned some of the London aldermen who refused to lend money. He prepared for war, scraping together what money he could and obtaining a grant through Strafford from Ireland. His position, however, was hopeless; his forces were totally undisciplined, and the Scots were supported by the parliamentary opposition in England. On Aug. 20 the Scots crossed the Tweed, beginning the so-called second Bishops' War, defeated the king's army at Newburn on the 28th, and subsequently occupied Newcastle and Durham. Charles at this juncture, on Sept. 24, summoned a great council of the peers; and on Oct. 21 a cessation of arms was agreed to by the treaty of Ripon, the Scots receiving £850 a day for the maintenance of the army, and further negotiations being transferred to London. On Nov. 3 the king summoned the Long Parliament.

At this great crisis, which would indeed have taxed the resolution and resource of the most cool-headed and sagacious statesman, Charles failed signally. He might have taken his stand on the ancient and undoubted prerogative of the crown, resisted all encroachments on the executive by the parliament by legal and constitutional means, which were probably ample, and in case of necessity have appealed to the loyalty of the nation to support him in arms; or he might have waived his rights, and, acknowledging the mistakes of his past administration, have united with the parliament and created once more that union of interests and sentiment of the monarchy with the nation which had made England so powerful. Charles, however, pretended to do both simultaneously or by turns, and therefore accomplished neither. The illegally imprisoned members of the last parliament, now smarting with the sense of their wrongs, were set free to stimulate the violence of the opposition to the king in the new assembly. Of Charles's double statecraft, however, the series of incidents which terminated the career of the great Strafford form the most terrible example. Strafford had come to London in Nov., having been assured by Charles that he "should not suffer in his person, honour or fortune," but was impeached and thrown into the Tower almost immediately. Charles took no steps to hinder the progress of the proceedings against him, but entered into schemes for saving him by bringing up an army to London, and this step exasperated Strafford's enemies, and added new zeal to the prosecution. On April 23, after the passing of the attainder by the Commons, he repeated to Strafford his former assurances of protection. On May 1 he appealed to the Lords to spare his life and be satisfied with rendering him incapable of holding office. On the 2nd he made an attempt to seize the Tower by force. On the 10th, yielding to the queen's fears and to the mob surging round his palace, he signed his death-warrant. "If my own person

only were in danger," he declared to the council, "I would gladly venture it to save my Lord Strafford's life; but seeing my wife, children, all my kingdom are concerned in it, I am forced to give way unto it." On the 11th he sent to the peers a petition for Strafford's life, the force of which was completely annulled by the strange postscript: "If he must die, it were a charity to reprieve him until Saturday." This tragic surrender of his great and devoted servant left an indelible stain upon the king's character, and he lived to repent it bitterly. One of his last admonitions to the prince of Wales was "never to give way to the punishment of any for their faithful service to the crown." It was regarded by Charles as the cause of his own subsequent misfortunes, and on the scaffold the remembrance of it disturbed his own last moments. The surrender of Strafford was followed by another stupendous concession by Charles, the surrender of his right to dissolve the parliament without its own consent, and the parliament immediately proceeded, with Charles's consent, to sweep away the star-chamber, high commission and other extra-legal courts, and all extra parliamentary taxation. Charles, however, did not remain long or consistently in the yielding mood. In June 1641 he engaged in a second army plot for bringing up the forces to London, and on Aug. 10 he set out for Scotland in order to obtain the Scottish army against the parliament in England; this plan was obviously doomed to failure and was interrupted by another appeal to force, the so-called Incident, at which Charles was suspected (in all probability unjustly) of having connived, consisting in an attempt to kidnap and murder Argyll, Hamilton and Lanark, with whom he was negotiating. Charles had also apparently been intriguing with Irish Roman Catholic lords for military help in return for concessions, and he was suspected of complicity in the Irish rebellion which now broke out. He left Scotland more discredited than ever, having by his concessions made, to use Hyde's words, "a perfect deed of gift of that kingdom," and without gaining any advantage.

Charles returned to London on Nov. 25, 1641, and was immediately confronted by the Grand Remonstrance (passed on the 22nd), in which, after reciting the chief points of the king's misgovernment, the parliament demanded the appointment of acceptable ministers and the constitution of an assembly of divines to settle the religious question. On Jan. 2, 1642, Charles gave office to the opposition members Colepeper and Falkland, and at the same time Hyde left the opposition partly to serve the king. Charles promised to take no serious step without their advice. Nevertheless, entirely without their knowledge, through the influence of the queen whose impeachment was intended, Charles on the 4th made the rash and fatal attempt to seize with an armed force the five members of the Commons, Pym, Hampden, Holles, Hesilrige and Strode, whom, together with Mandeville (afterwards earl of Manchester) in the Lords, he had impeached of high treason. No English sovereign ever had (or has since that time) penetrated into the House of Commons. So complete and flagrant a violation of parliamentary liberties, and an appeal so crude and glaring to brute force, could only be justified by complete success; but the court plans had been betrayed, and were known to the offending members, who, by order of the House, had taken refuge in the city before the king's army with the soldiers. Charles, on entering the House, found "the birds flown," and returned baffled, having thrown away the last chance of a peaceful settlement. (See LENTHALL, WILLIAM.) The next day Charles was equally unsuccessful in obtaining their surrender in the city. "The king had the worst day in London yesterday," wrote a spectator of the scene, "that ever he had, the people crying 'privilege of parliament' by thousands, and prayed God to turn the heart of the king, shutting up their shops and standing at their doors with swords and halberds." On the 10th, amidst general manifestations of hostility, Charles left Whitehall to prepare for war, destined never to return till he was brought back by his victorious enemies to die.

Several months followed spent in manoeuvres to obtain the control of the forces and in a paper war of controversy. On April 23 Charles was refused entry into Hull, and on June 4, the parliament sent to him the "Nineteen Propositions," claiming

the whole sovereignty and government for the parliament, including the choice of the ministers, the judges, and the control of the army, and the execution of the laws against the Roman Catholics. The military events of the war are described in the article GREAT REBELLION.

The negotiations carried on at Uxbridge during Jan. and Feb. 1645 failed to secure a settlement, and on June 14 the crushing defeat of the king's forces, by the new model army, at Naseby practically ended the civil war. Charles, however, refused to make peace on Rupert's advice, and considered it a point of honour "neither to abandon God's cause, injure my successors, nor forsake my friends." His chief hope was to join Montrose in Scotland, but his march north was prevented by the parliamentary forces, and on Sept. 24 he witnessed from the walls of Chester the rout of his followers at Rowton Heath. He now entered into a series of intrigues, mutually destructive, which, becoming known to the different parties, exasperated all and diminished still further the king's credit. One proposal was the levy of a foreign force to reduce the kingdom; another, the supply through the marquis of Ormonde of 10,000 Irish. Correspondence relating to these schemes, fatally compromising as they were if Charles hoped ever to rule England again, was discovered by his enemies, including the Glamorgan treaty, which went much further than the instructions to Ormonde, but of which the full responsibility has never been really traced to Charles, who on Jan. 29, 1646, disavowed his agent's proceedings. He simultaneously treated with the parliament, and promised toleration to the Roman Catholics if they and the pope would aid in the restoration of the monarchy and the church. Nor was this all. The parliamentary forces had been closing round Oxford. On April 27 the king left the city, and, on May 5, gave himself up to the Scottish army at Newark, arriving on the 13th with them at Newcastle. On July 13 the parliament sent to Charles the "Newcastle Propositions," which included the extreme demands of Charles's acceptance of the Covenants, the abolition of episcopacy and establishment of Presbyterianism, severer laws against the Roman Catholics and parliamentary control of the forces, with the withdrawal of the Irish cessation, and a long list of royalists to be exempted from pardon. Charles returned no definite answer for several months. He imagined that he might now find support in Scottish royalism, encouraged by Montrose's series of brilliant victories, but these hopes were destroyed by the latter's defeat at Philiphaugh on Sept. 3. The Scots insisted on the Covenant and on the permanent establishment of Presbyterianism, while Charles would only consent to a temporary maintenance for three years. Accordingly the Scots, in return for the payment of part of their army arrears by the parliament, marched home on Jan. 30, 1647, leaving Charles behind, who under the care of the parliamentary commissioners was conducted to Holmby House. Thence on May 12 he sent his answer to the Newcastle Propositions, offering the militia to the parliament for ten years and the establishment of Presbyterianism for three, while a final settlement on religion was to be reached through an assembly of 20 divines at Westminster. But in the midst of the negotiation with the parliament Charles's person was seized, on June 3, 1647, by Cornet Joyce under instructions of the army, which soon afterwards, occupied London and overpowered the parliament, placing Charles at Hampton Court.

If Charles could have remained firm to either one or the other faction, and have made concessions either to Presbyterianism or on the subject of the militia, he might even now have prevailed. But he had learned nothing by experience and continued at this juncture his characteristic policy of intrigue and double-dealing, "playing his game," to use his own words, negotiating with both parties at once, not with the object or wish to arrive at a settlement with either, but to augment their disputes, gain time and profit ultimately by their divisions. The "Heads of the Proposals," submitted to Charles by the army on July 28, 1647, were terms conceived on a basis far broader and more statesman-like than the Newcastle Propositions, and such as Charles might well have accepted. The proposals on religion anticipated the

Toleration Act of 1689. There was no mention of episcopacy, and its existence was thereby indirectly admitted, but complete religious freedom for all Protestant denominations was provided, and the power of the church to inflict civil penalties abolished, while it was also suggested that dangers from Roman Catholics and Jesuits might be avoided by means other than enforcing attendance at Church. The parliament was to dissolve itself and be succeeded by biennial assemblies elected on a reformed franchise, not to be dissolved without their own consent before 120 days, and not to sit more than 240 days in the two years. A council of state was to conduct the foreign policy of the state and conclude peace and war subject to the approval of parliament, and to control the militia for ten years, the commanders being appointed by parliament, as also the officers of state for ten years. No peer created since May 21, 1642, was to sit in parliament without consent of both Houses, and the judicial decisions of the House of Lords were to be ratified by the Commons. Only five persons were excepted from amnesty, but royalists were not to hold office for five years and not to sit in the Commons till the end of the second biennial parliament. Proposals for a series of reforms were also added. Charles, however, was at the same time negotiating with Lauderdale for an invasion of England by the Scots, and imagined he could win over Cromwell and Fairfax by "proffers of advantage to themselves." The precious opportunity was therefore allowed to slip by. On Sept. 9 he rejected the proposals of the parliament for the establishment of Presbyterianism. His hopes of gaining advantages by playing upon the differences of his opponents proved a complete failure. Fresh terms were drawn up by the army and parliament together on Nov. 10, but before these could be presented, Charles, on the 11th, had escaped to Carisbrooke Castle in the Isle of Wight. Thence on the 16th he sent a message offering Presbyterianism for three years and the militia for his lifetime to the parliament, but insisting on the maintenance of episcopacy. On Dec. 28 he refused his assent to the Four Bills, which demanded the militia for parliament for 20 years, and practically forever annulled the honours recently granted by the king and his declarations against the Houses, and gave to parliament the right to adjourn to any place it wished. On Jan. 3, 1648, the Commons agreed to a resolution to address the king no further, in which they were joined by the Lords on the 15th.

Charles had meanwhile taken a further fatal step which brought about his total destruction. On Dec. 26, 1647, he had signed at Carisbrooke with the Scottish commissioners the secret treaty called the "Engagement," whereby the Scots undertook to invade England on his behalf and restore him to the throne on condition of the establishment of Presbyterianism for three years and the suppression of the sectarians. In consequence the second civil war broke out and the Scots invaded England under Hamilton. The royalist risings in England were soon suppressed, and Cromwell gained an easy and decisive victory over the Scots at Preston. Charles was now left alone to face his enemies, with the whole tale of his intrigues and deceptions unmasked and exposed. The last intrigue with the Scots was the most unpardonable in the eyes of his contemporaries, no less wicked and monstrous than his design to conquer England by the Irish soldiers; "a more prodigious treason," said Cromwell, "than any that had been perfected before; because the former quarrel was that Englishmen might rule over one another; this to vassalize us to a foreign nation." Cromwell, who up to this point had shown himself foremost in supporting the negotiations with the king, now spoke of the treaty of Newport, which he found the parliament in the act of negotiating on his return from Scotland, as "this ruining hypocritical agreement." Charles had engaged in these negotiations only to gain time and find opportunity to escape. He had stipulated that no concession from him should be valid unless an agreement were reached upon every point. He had now consented to most of the demands of the parliament, including the repudiation of the Irish cessation, the surrender of the delinquents and the cession of the militia for twenty years, and of the offices of state to parliament, but remained firm in his refusal to abolish episcopacy, consenting only to Presbyterianism for

three years. Charles's devotion to the church is undoubted. In April 1646, before his flight from Oxford, inspired perhaps by superstitious fears as to the origin of his misfortunes, he had delivered to Sheldon, afterwards archbishop of Canterbury, a written vow (now in the library of St. Paul's cathedral) to restore all church lands held by the crown on his restoration to the throne; and almost his last injunction to the prince of Wales was that of fidelity to the national church. His present firmness, however, in its support was caused probably less by his devotion to it than by his desire to secure the failure of the whole treaty, and his attempts to escape naturally weakened the chances of success. Cromwell now supported the petitions of the army against the treaty. On Nov. 16 the council of officers demanded the trial of the king, "the capital and grand author of our troubles," and on Nov. 27 the parliamentary commissioners returned from Newport without having secured Charles's consent. Charles was removed to Hurst Castle on Dec. 1, where he remained till the 19th, thence being taken to Windsor, where he arrived on the 23rd. On the 6th "Pride's Purge" had removed from the Commons all those who might show any favour to the king. On the 25th a last attempt by the council of officers to come to terms with him was repulsed. On Jan. 1 the remnant of the Commons resolved that Charles was guilty of treason by "levying war against the parliament and kingdom of England"; on the 4th they declared their own power to make laws without the lords or the sovereign, and on the 6th established a "high court of justice" to try the king. On the 19th Charles was brought to St. James Palace, and on the next day his trial began in Westminster Hall, without the assistance of any of the judges, who all refused to take part in the proceedings. He laughed aloud at hearing himself called a traitor, and immediately demanded by what authority he was tried. He had been in treaty with the parliament in the Isle of Wight and taken thence by force; he saw no lords present. He was told by Bradshaw, the president of the court, that he was tried by the authority of the people of England, who had elected him king; and when Charles retorted that he was king by inheritance and not by election, and that England had been an hereditary kingdom for more than 1,000 years, Bradshaw cut short the discussion by adjourning the court. On the 22nd Charles repeated his reasoning, adding, "It is not my case alone; it is the freedom and liberty of the people of England, and do you pretend what you will, I stand more for their liberties, for if power without law may make laws . . . I do not know what subject he is in England that can be sure of his life or anything he calls his own." On the 23rd he again refused to plead. The court was adjourned, and there were several signs that the army in their prosecution of the king had not the nation at their back. While the soldiers had shouted "Justice! justice!" as the king passed through their ranks, the civilian spectators from the end of the hall had cried "God save the king!" After some considerable opposition and reluctance on the 26th the court decided unanimously upon his execution, and on the 27th Charles was brought into court for the last time to hear his sentence. His request to be heard before the Lords and Commons was rejected, and his attempts to answer the charges of the president were silenced. Sentence was pronounced, and the king was removed by the soldiers, uttering his last broken protest: "I am not suffered to speak. Expect what justice other people will have."

In these last hours, Charles, who was probably weary of life, showed a remarkable dignity and self-possession, and a firm resignation supported by religious faith and by the absolute conviction of his own innocence, which, says Burnet, "amazed all people and that so much the more because it was not natural to him. It was imputed to a very extraordinary measure of supernatural assistance . . . ; it was owing to something within himself that he went through so many indignities with so much true greatness without disorder or any sort of affectation." Nothing in his life became Charles like the leaving it. "He nothing common did or mean Upon that memorable scene." On the morning of Jan. 29 he said his last sad farewell to his younger children, Elizabeth and Henry duke of Gloucester. On the 30th at ten

o'clock he walked across from St. James's to Whitehall, calling on his guard "in a pleasant manner" to walk apace, and at two he stepped upon the scaffold from a window, probably the middle one, of the Banqueting House. He was separated from the people by large ranks of soldiers, and his last speech only reached Juxon and those with him on the scaffold. He declared that he had desired the liberty and freedom of the people as much as any; "but I must tell you that their liberty and freedom consists in having government. . . . It is not their having a share in the government; that is nothing appertaining unto them. A subject and a sovereign are clean different things." These, together with his declaration that he died a member of the Church of England, and the mysterious "Remember" spoken to Juxon, were Charles's last words. "It much discontents the citizens," wrote a spectator; "ye manner of his deportment was very resolutely with some smiling countenances, intimating his willingness to be out of his troubles." (*Notes and Queries*, 7th ser., viii. 326). "The blow I saw given," wrote another, Philip Henry, "and can truly say, with a sad heart, at the instant whereof I remember well, there was such a grone by the Thousands then present as I never heard before and desire I may never hear again. There was according to order one Troop immediately marching fromwards Charing Cross to Westminster and another fromwards Westminster to Charing Cross, purposely to mask" (i.e., to overpower) "the people and to disperse and scatter them, so that I had much adoe amongst the rest to escape home without hurt" (*Letters and Diaries of P. Henry* [1882], 12).

Amidst such scenes of violence was at last effected the destruction of Charles. "It is lawful," wrote Milton, "and hath been held so through all ages for any one who have the power to call to account a Tyrant or wicked King, and after due conviction to depose and put him to death" (*Tenure of Kings and Magistrates*). But here (it might well be contended) there had been no "due conviction." The execution had been the act of the king's personal enemies, an act technically illegal, morally unjustifiable because the supposed crimes of Charles had been condoned by the later negotiations with him, and indefensible on the ground of public expediency, for the king's death proved a far greater obstacle to the re-establishment of settled government than his life could have been. The result was an extraordinary revulsion of feeling in favour of Charles and the monarchy, in which the incidents of his misgovernment were completely forgotten. He soon became in the popular veneration a martyr and a saint. His fate was compared with the Crucifixion, and his trials and sufferings to those of the Saviour. Handkerchiefs dipped in his blood wrought "miracles," and the *Eikon Basilike*, published on the day of his funeral, presented to the public a touching, if not a genuine, portrait of the unfortunate sovereign. At the Restoration the anniversary of his death was ordered to be kept as a day of fasting and humiliation, and the service appointed for use on the occasion was only removed from the prayer book in 1859. The conception of Charles as a martyr for religion has still its appeal. "Had Charles been willing to abandon the church and give up episcopacy," says Bishop Creighton, "he might have saved his throne and his life. But on this point Charles stood firm, for this he died and by dying saved it for the future" (*Lectures on Archbishop Laud* [1895], p. 25). Gladstone, Keble, Newman write in the same strain. "It was for the Church," says Gladstone, "that Charles shed his blood upon the scaffold" (*Remarks on the Royal Supremacy* [1850], p. 57). "I rest," says Newman, "on the scenes of past years, from the Upper Room in Acts to the Court of Carisbrooke and Uxbridge."

The injustice and violence of the king's death, however, the pathetic dignity of his last days, and the many noble traits in his character, cannot obscure the ultimate causes of his downfall and destruction. The constitutional struggle between the crown and parliament had not been initiated by Charles I. In some degree he inherited a situation for which he was not responsible. According to the ideas of kingship which then prevailed, he can not justly be blamed for defending the prerogatives of the crown as precious and sacred personal possessions which it was his duty to hand down intact to his successors; for his refusal to yield up

the control of the executive to the parliament or the army; or for his defence of the national church. But the great constitutional and religious points of dispute between the king and parliament, though doubtless involving principles vital to the national interests, would not alone have sufficed to destroy Charles. Monarchy was too much venerated, was too deeply rooted in the national life, to be hastily and easily extirpated. The statecraft of Charles had consisted throughout in an unhappy series of subterfuges, falsehoods and deception from the fraud concerning the concessions to the Roman Catholics at his marriage, and the evasions with which he met the Petition of Right, to the abandonment of Strafford, and the simultaneous negotiation with, and betrayal of, all parties. The bond of union between his people and himself had been early broken, and compromise is only possible between parties which can trust one another, and which are sincere in their endeavour to reach agreement. Thus on Charles himself largely falls the responsibility for the catastrophe.

His character and motives fill a large place in English history, but they have never been fully understood and possibly were largely due to physical causes. His weakness as a child was so extreme that his life was despaired of. He outgrew physical defects, and as a young man excelled in horsemanship and in the sports of the times, but always retained an impediment of speech. At the time of his accession his reserve and reticence were especially noticed. Buckingham was the only person who ever enjoyed his friendship, and after his death Charles placed entire confidence in no man. His character was marked by a weakness which shirked and postponed the settlement of difficulties, by a meanness and ingratitude even when dealing with his most devoted followers, by an obstinacy which only feigned compliance, by an untruthfulness which differed widely from his son's unblushing deceit. Yet Charles, in spite of his failings, had many fine qualities. Clarendon, who was fully conscious of them, who does not venture to call him a good king, and allows that "his kingly virtues had some mixture and alloy that hindered them from shining in full lustre," declares that "he was if every any, the most worthy of the title of an Honest Man, so great a lover of justice that no temptation could dispose him to a wrongful action except that it was disguised to him that he believed it just," "the worthiest of gentlemen, the best master, the best friend, the best husband, the best father and the best Christian that the age in which he lived produced." With all its deplorable mistakes and failings Charles I.'s reign belongs to a sphere infinitely superior to that of his unscrupulous, corrupt, selfish but more successful son. His private life was without a blemish. Immediately on his accession he had suppressed the disorder which had existed in the household of James I., and let it be known that whoever had business with him "must never approach him by backstairs or private doors" (Salveti's Corresp. in *Hist. MSS. Comm.* 11th Rep. app. pt. i. p. 6). He maintained a strict sobriety in food and dress. He had a fine artistic sense, and Milton reprehends him for having made Shakespeare, "the closest companion of his solitudes." "Monsieur le Prince de Galles," wrote Rubens in 1625, "est le prince le plus amateur de la peinture qui soit au monde." He succeeded in bringing together during 20 years an unrivalled collection, of which a great part was dispersed at his death. He showed a noble insensibility to flattery. He was deeply and sincerely religious. He wished to do right, and was conscious of the purity of his motives. Those who came into contact with him, even the most bitter of his opponents, were impressed with his goodness. The great tragedy of his life, to be read in his well-known, dignified, but weak and unhappy features, and to be followed in his inexplicable and mysterious choice of baneful instruments, such as Rupert, Laud, Hamilton, Glamorgan, Henrietta Maria—all in their several ways working out his destruction—seems to have been inspired by a fateful insanity or infirmity of mind or will, recalling the great Greek dramas in which the poets depicted frenzied mortals rushing into their own destruction, impelled by the unseen and superior powers.

The king's body, after being embalmed, was buried by the few followers who remained with him to the last, hastily and without

any funeral service, which was forbidden by the authorities, in the tomb of Henry VIII., in St. George's Chapel, Windsor, where his coffin was identified and opened in 1813. An "account of what appeared" was published by Sir Henry Halford, and a bone abstracted on the occasion was replaced in the vault by the prince of Wales (afterwards Edward VII.) in 1888. Charles I. left, besides three children who died in infancy, Charles (afterwards Charles II.); James (afterwards James II.); Henry, duke of Gloucester (1639-1660); Mary (1631-1660), who married William of Orange; Elizabeth (1635-1650); and Henrietta, duchess of Orleans (1644-1670).

BIBLIOGRAPHY.—The leading authority for the life and reign of Charles I. is S. R. Gardiner, *History of England* (1883), and *History of the Great Civil War* (1893), with references there given; an excellent account of Charles I.'s reign is in G. M. Trevelyan, *England under the Stuarts* (1904, 12th ed. rev. 1925). Among recent works may be mentioned E. B. Chancellor, *Life of Charles I., 1600-1625* (1886); *The Manner of the Coronation of King Charles I.* (ed. by C. Wordsworth, Henry Bradshaw Soc., 1892); C. CHARLES II. (1630-1685), king of Great Britain and Ireland, and son of Charles I. and Henrietta Maria, was born on May 29, 1630. About 1638 the duke of Newcastle was appointed as his governor, but his education was interrupted by the Civil War. In 1645 Charles I. sent him into the west of England, where his council included, among others, Sir Edward Hyde. In March 1646 the Royalist defeats drove him to the Scilly Isles and later to Jersey, and in July he joined his mother in Paris. He remained there under her control for two years, and continued his studies, Hobbes being his tutor for mathematics.

In 1648 Charles cruised with some English ships off the mouth of the Thames, but effected nothing and retired to Holland. In Jan. 1649 he sent a blank sheet of paper, bearing his signature, to parliament, for the insertion of any terms which would save his father's life. After Charles I.'s execution on Jan. 30, 1649, he was proclaimed king in Scotland and parts of Ireland and in the Channel Islands. He went to Jersey in September, but was obliged to retire to Breda (Feb. 1650), and from that place he came to terms with the Scots, accepting the Covenant and abandoning Montrose. He landed in Scotland on June 23, 1650, after pledging himself to Presbyterianism in both Scotland and England. An attempt to escape from the Covenanters, known as "the Start," failed, and on Jan. 1, 1651, Charles was crowned as king of Scots at Scone. Cromwell's advance forced him to march into England and on Sept. 3 Cromwell defeated him at Worcester. Charles showed great courage in the battle, and after an amazing series of adventures, including his concealment in the "Royal Oak" at Boscobel, sailed from Brighton for France on Oct. 15.

His advisers were henceforward the legitimists, Hyde, Ormond and Nicholas. Plots for risings in England and Scotland and for Cromwell's assassination failed. In 1654 Cromwell's negotiations with France drove Charles to Germany, but after Cromwell's alliance with France he made a treaty with Spain (April 1656) and resided at Bruges or Brussels. His chief source of income

was a Spanish pension; nevertheless he was very poor. Cromwell's death did not immediately alter his position and in 1659 he went to Fuenterrabia, where the Peace of the Pyrenees was being negotiated between France and Spain, to ask for military aid. This journey and a Royalist rising in England were alike fruitless.

Events in England brought about the Restoration, which the Royalists alone could not have accomplished. By the end of 1659 a return to the old Constitution was the only escape from the alternatives of military government or anarchy. Monck (Albemarle) advanced with an armed force from Scotland; by recalling the secluded members of the Long Parliament, power was transferred from the Independents to the Presbyterians. A "Free Parliament" was summoned to meet in April 1660 while Monck opened negotiations with Charles, who, following his advice, issued the Declaration of Breda (*see* BREDA) April 4. Largely the work of Hyde, it promised a general amnesty and liberty of conscience, and guaranteed the transfers of land, leaving the final settlement in each case to parliament; it also promised full arrears of pay to all ranks in the army. The Convention Parliament, in which the secular peers again sat, accepted the Declaration and Charles was proclaimed king on May 8. On May 26 he landed at Dover, where he was met by Monck, and on May 29, amid universal rejoicing, arrived at Whitehall.

The agreement of Charles and Monck in leaving the settlement to parliament meant that the Restoration was a restoration of parliamentary government, not of personal monarchy. Charles was not a conqueror and had no armed force of his own, while during the last 20 years almost all classes in England had acquired a permanent interest in politics. The administration could not be carried on without the help of men who had already been employed by the revolutionary Governments and the new council included faithful Royalists and ex-rebels. The willing co-operation of the Convention and the unbounded loyalty of its successor in its earlier years encouraged Charles to entrust many matters to parliament. The Restoration dissolved the legislative union with Scotland and Ireland, but led to the re-establishment of their separate parliaments. In Scotland it was complete, and brought back Episcopacy and repression; in Ireland the Cromwellian settlement was firmly established and was upheld by English opinion.

Hyde, created earl of Clarendon, was still Charles's chief adviser, and directed the work of reconstruction in England. All the acts of the revolutionary Governments since 1642 were held to be invalid; judicial proceedings since that date were confirmed by a special act. The Navigation Act of 1651 was re-enacted; the abolition of feudal incidents, completed in 1656, was maintained by a new act. The Indemnity bill led to disputes between Charles and parliament, Charles desiring lenity. Thirteen regicides and young Sir Henry Vane were executed; 25 regicides, Lambert and Hesilrigge were imprisoned for life; otherwise the amnesty was complete. Crown and Church lands, and other lands sequestered by the revolutionary Governments, reverted to their former owners, but Royalists who had sold part of their lands to meet the fines inflicted on them received no compensation. By means of special taxes the army was paid off by Feb. 1661; Charles, who had only a few Life and Foot Guards, retained Monck's regiment of infantry, known henceforward as the Coldstream Guards, and a cavalry regiment, the Blues. By 1685, mainly by the return of regiments from Dunkirk and Tangier, this force was increased by five regiments of foot and one of dragoons. The Government's income was fixed at £1,200,000, but the sources allocated did not produce that amount, and the Government was involved from the start in pecuniary difficulties for which it was not responsible.

The restoration of the Church was slower. Charles was pledged to toleration, and plans for comprehension were put forward. The Convention was dissolved in Dec. 1660 without settling anything, and the Savoy conference, between Anglicans and Presbyterians, proved sterile. Charles was crowned on April 23, 1661, and a new parliament met on May 8; as it sat until 1679 it is called the Long Parliament of the Restoration, and sometimes the Cavalier or the Pensionary Parliament. It was composed at

the start almost entirely of Anglicans and thorough-going Royalists, and Charles and Clarendon could not restrain it on religious questions. The bishops returned to the Upper House on Nov. 20, 1661. On May 19, 1662, the Act of Uniformity was passed, enjoining the use of the Book of Common Prayer, which had been specially revised, and included new services of Jan. 30 and May 29 (the dates of the execution of Charles I. and the Restoration); as a result about 1,200 of the clergy, who refused to conform, left their livings on St. Bartholomew's Day (Aug. 12); another 800 had already been ejected. The Puritans, who had hitherto tried to gain control of the national Church while remaining within it, took up a position definitely outside it; they came to be known as Nonconformists or Dissenters. Charles tried to relieve them and the Roman Catholics by a declaration issued on Dec. 26, 1662, but it was opposed by Clarendon and by parliament; and a series of acts was passed, including the Conventicle and Five Mile Acts, forbidding the Nonconformists their special forms of worship; it is unjustly called the Clarendon Code. The Corporation Act (1661) drove the Nonconformists from power in the boroughs; the Press Act (1662), establishing a censorship, and the repeal of the Triennial Act (1664) completed the reconstruction of the Constitution.

Charles's foreign policy was largely a continuation of Cromwell's, although based on material rather than on religious considerations. Peace was made with Spain, but Jamaica and Dunkirk were retained, and Charles, when he married the Portuguese Catherine of Braganza in 1662, pledged himself to give Portugal military support in its struggle with Spain. The marriage, which brought Bombay and Tangier to England as parts of Catherine's dowry, drew England closer to France; the two countries were further connected by the marriage of Charles's sister, Henrietta Anne, to the duke of Orleans and by the sale of Dunkirk to France. Dunkirk was a costly possession and had lost most of its military or naval value, especially after the acquisition of Tangier. In 1664 English commercial expansion and minor political differences led to war with the Dutch. The struggle was indecisive, but England was weakened by the Great Plague in 1665, and the Fire of London in 1666. Financial exhaustion led to negotiations, and in 1667 the Dutch, by burning the English ships in the Medway, enforced the conclusion of the Peace of Breda. Both sides kept their conquests, England obtaining New York and New Jersey. Parliament demanded a sacrifice and attacked Clarendon. Charles was annoyed by his opposition to toleration and tired of his lectures on his private misconduct; to the delight of the courtiers and the younger politicians he allowed him to be exiled.

Free from tutelage, Charles determined to follow his own policy. He disliked parliamentary control and believed that he could establish a strong monarchy upon the alliance of the Catholics and the dissenters; his desire for toleration and his personal inclination towards Catholicism, increased by his knowledge of the attitude of his brother James, duke of York, alike recommended this policy. He also wanted to revenge himself on the Dutch for his humiliation at Chatham. Henceforward he never gave complete confidence to any minister. He now employed Clifford and Arlington—both Catholics—but allowed Buckingham some show of power. These three, with Ashley and Lauderdale, formed the notorious Cabal, so-called because the first letters of their names formed that word. It was not a ministry in the modern sense, there being no common policy or joint responsibility. Charles hoped to attain his ends by the support of Louis XIV., who, engaged in promoting his queen's claims to the Spanish succession, was prepared to buy the alliance or the neutrality of England.

The Triple Alliance, formed in 1668 between England, Holland and Sweden, appeared for a time to threaten Louis's projects. It was extremely popular in England, but Charles excused his share in it to Louis, whom it estranged from the Dutch. In 1669 Charles declared to the French ambassador his desire to be reconciled to Rome, and through the duchess of Orleans negotiated with Louis the secret Treaty of Dover, signed on May 22, 1670. Charles was to declare himself a Catholic; in view of possible disturbances Louis was to pay him £150,000 and to provide

6,000 men; thereafter France and England were to join in a war against the Dutch. (*See DOVER, SECRET TREATY OF.*) Only Clifford and Arlington among the ministers signed this treaty; in Dec. 1670 the whole Cabal signed a feigned treaty, which omitted the conversion clauses. Charles was easily led to postpone them; what importance he attached to them cannot be determined. In 1671 Louis sent to England, to become Charles's mistress, Louise de Querouaille, later duchess of Portsmouth.

The war against the Dutch began in 1672; at the same time Charles issued the Declaration of Indulgence, suspending the penal laws, and postponed all payments of assignments on the revenue; this was the "Stop of the Exchequer," affecting the London bankers. The war, although it established British commercial and naval supremacy, was unpopular. In 1673 parliament forced Charles to cancel the Declaration of Indulgence and to pass the Test Act, which drove Catholics, including Clifford and James, from office. In 1674 Charles was obliged to make peace with the Dutch.

Danby (Sir Thomas Osborne, later duke of Leeds) succeeded the Cabal. His policy, based on the alliance of Church and Crown, was calculated to detach from the opposition the loyalists driven to it by hatred of the Cabal; by patronage and corruption he increased their number and formed a strong "Court Party" in parliament. Ashley, now earl of Shaftesbury, led the opposition "Country Party" to which the bye-elections furnished recruits. It was generally predominant, but French subsidies enabled Charles to resist it. Danby was obliged to concur in this, but tried to direct foreign policy along more popular lines, and in Nov. 1677 brought about the marriage of James's daughter, Mary, with William of Orange (afterwards William III. and Mary II.). Charles turned against Louis who, not without bribery, persuaded the Country Party to refuse supplies for the army; he then made the Peace of Nijmegen with the Dutch.

Hatred of the Cabal and distrust of Charles had prepared the way for Titus Oates, who, in Aug. 1678 denounced an intended rising of the Catholics. This, the "Popish Plot," was almost entirely fictitious, as Charles readily discovered, but received apparent confirmation from Coleman's letters and Godfrey's death. Shaftesbury promoted the ensuing general panic. Charles let the agitation take its course, intervening only when Oates accused the queen; between 1678 and 1680 some 35 victims were executed, although Charles knew most of them to be innocent of the charges brought against them. He now realized the importance of the unhesitating support of the Church. He dissolved parliament in Jan. 1679 to save Danby from impeachment; for Louis XIV. had revenged himself on Danby by divulging one of the letters written by Charles's order relating to the subsidy. The Press Act lapsed immediately, resulting in a flood of pamphlets and newspapers. James was sent abroad; an experimental reform of the Council failed; the new parliament had to be dissolved within a few months. The exclusion of James from the succession to the throne was now proposed; his place was to be taken by Monmouth, Charles's eldest illegitimate son. A new parliament met in Oct. 1680; the Exclusion bill passed the Commons but was defeated in the Lords by the genius of Halifax. The Commons refused to consider the alternative plan, which Charles was prepared to accept, of limiting the powers of a Catholic successor. In March 1681 a new parliament met at Oxford, where the London mob could not dominate it, but as the Exclusion bill was introduced immediately, it was dissolved after sitting for one week only. Henceforward Charles governed without parliaments.

It was at this time that the terms "Whig" and "Tory" emerged as party names. Charles attacked the leading Whigs but the London grand jury threw out the charge against Shaftesbury. A writ of *quo warranto* brought against the City of London compelled it to surrender its charter, whereupon a general attack was made on the municipal charters throughout the kingdom. The new charters gave the Tories control over the appointment of municipal officers and the return of the borough members. James returned from exile. Some of the defeated Whigs formed the Rye House Plot in 1683; its discovery led to the execution of Lord William Russell and Algernon Sidney. The Tory reaction had

now reached its climax, but shortage of income compelled Charles, in spite of subsidies from Louis XIV., to abandon Tangier (1683) and to allow the navy to decay; meanwhile he could only watch the increase of French power, including the seizure of Strasbourg. He may have been considering a change of policy when he was taken seriously ill on Feb. 2, 1685. He made a profession of the Catholic faith, received the sacrament and died on Feb. 6.

In appearance Charles was tall and dark; besides numerous portraits there is a wax effigy, taken from the corpse, in Westminster Abbey. He was active, walked rapidly and was an excellent horseman; he loved all outdoor sports, but was happiest at sea. He was a keen patron of the turf and rode himself. He had an excellent constitution, was careful about his diet and rarely drank to excess. His manners were excellent; he was affable and easy, but too good-natured to be able to refuse requests. His wit was more suitable for a private gentleman than for a king, but was free from malice. His fits of anger were rare and brief. His memory was excellent. His gaiety, good nature and freedom from pretence made him generally popular. His notorious lasciviousness contained no "seraphic" element; he accepted the mistresses chosen for him. The sums he spent on them did not embarrass his finances, but made it difficult for him to ask parliament for money for other purposes. He had no legitimate children; the most important of his many illegitimate children were: By Lucy Walter, James Scott, duke of Monmouth and Buccleuch (1649-1685); by Lady Castlemaine (later duchess of Cleveland), Charles, Henry and George Fitzroy, dukes of Southampton, Grafton and Northumberland, and the countesses of Sussex and Lichfield; by the duchess of Portsmouth, Charles Lennox, duke of Richmond; by Nell Gwyn, Charles Beauclerk, duke of St. Albans; by Catherine Peg, Charles FitzCharles, earl of Plymouth; by Lady Shannon, the countess of Yarmouth; by Mary Davis, the countess of Derwentwater. Nell Gwyn, an actress, was the most popular of the mistresses and Charles appreciated her wit.

Charles once said that "he was no atheist, but he could not think God would make a man miserable only for taking a little pleasure out of the way." He inclined towards Roman Catholicism, partly on political grounds, but Halifax, perhaps reflecting Charles's own view, thought that creed most compatible with his lax morality. The date of his change of belief is uncertain, but in 1660 he was apparently determined to marry a Catholic. He was not reconciled to Rome until his death-bed, and attended Anglican services regularly during his life. He was a good judge of sermons and did not object to remonstrances so long as he was not expected to reform and they were in good taste. His desire for toleration was based on indifference and good nature and the memory of his promises, not on principle. Charles was interested in science, had his own laboratory, and gave the Royal Society its charter. He encouraged applied science, especially when it concerned navigation; his knowledge of naval architecture was praised by Pepys, but was considered by most contemporaries to be greater than his rank permitted. He patronized the theatre and enjoyed the lighter forms of literature.

The reign was politically sterile because Charles's achievements were undone and his foreign policy reversed by the Revolution of 1688; but the transfer of power from the Crown to the House of Commons went on steadily during the existence of the Long Parliament of the Restoration. It was a time of administrative progress, notably in the navy and in the Treasury system, and between 1660 and 1688 the administration of the old colonial empire reached its highest point of efficiency. Charles himself contributed by his interest in naval, commercial and colonial expansion, but sacrificed these objects too easily to his personal and dynastic policy. Attempts to vindicate the latter have failed; much of his conduct admits no justification. He was too lazy and fond of pleasure to apply himself steadily to business, but energetic on occasion and always intelligent. Halifax notes his powers of dissimulation. He was unwilling to face prolonged opposition, being determined "not to go on his travels again." He was selfish and callous but not vindictive. During the reign there was great material and intellectual progress and some improvement in manners. Writers who denounce the morals of the age rely too

much on Pepys and Grammont. The tendency has been to judge the country at large by Charles's characteristics, and to dwell on his vices without considering his gifts. Closer study is modifying many of the older verdicts.

(See also **ENGLISH HISTORY**.)

CHARLES I. and II., kings of France. By the French, Charles the Great, Roman emperor and king of the Franks, is reckoned the first of the series of French kings named Charles (see **CHARLES THE GREAT**). Similarly the emperor Charles II. the Bald (*q.v.*) is reckoned as Charles II. of France. In some enumerations the emperor Charles III. the Fat (*q.v.*) is reckoned as Charles II. of France, Charlemagne not being included in the list, and Charles the Bald being styled Charles I.

CHARLES III., the Simple (879-929), king of France, was a posthumous son of Louis the Stammerer and of his second wife Adelaide. On the deposition of Charles the Fat in 887 he was excluded from the throne owing to his youth; but during the reign of Odo, who had succeeded Charles, he gained the recognition of a certain number of notables and secured his coronation at Reims on Jan. 28, 893. He now obtained the alliance of the emperor, and forced Odo to cede part of Neustria. In 898, by the death of his rival (Jan. 1), he obtained possession of the whole kingdom. His most important act was the treaty of Saint-Clair-sur-Epte with the Normans in 911. Some of them were baptized; the territory which was afterwards known as the duchy of Normandy was ceded to them; but the story of the marriage of their chief Rollo with the king's sister Gisda, related by the chronicler Dudo of Saint Quentin, is very doubtful. The same year Charles, on the invitation of the barons, took possession of the kingdom of Lotharingia. In 920 the barons, jealous of the growth of the royal authority and discontented with the favour shown by the king to his counsellor Hagano, rebelled, and in 922 elected Robert, brother of King Odo, in place of Charles. Robert was killed in the battle of Soissons, but the victory remained with his party, who elected Rudolph, duke of Burgundy, king. In his extremity Charles trusted himself to Herbert, count of Vermandois, who deceived him and imprisoned him at Château-Thierry and afterwards at Péronne, where he died on Oct. 7, 929. In 907 he had married Frederona, sister of Bovo, bishop of Chalons. After her death he married Eadgyfu (Odgiva), daughter of Edward the Elder, king of the English, who was the mother of Louis IV. (See **NORMANDY**.)

See A. Eckel, *Charles le Simple* (1899).

CHARLES IV. (1294-1328), king of France, called **THE FAIR**, was the third and youngest son of Philip IV. the Fair and Jeanne of Navarre. In 1316 he was created count of La Marche, and succeeded his brother Philip V. as king of France and Navarre early in 1322. He followed the policy of his predecessors in enforcing the royal authority over the nobles, but the machinery of a strong centralized government increased the royal expenditure, to meet which Charles had recourse to doubtful financial expedients. Civil offices were put up to auction; duties were imposed on exported merchandise and on goods brought into Paris; the salaries of the magistrates were made dependent on the exaction of heavy fines; on the pretext of a crusade to free Armenia from the Turks, Charles obtained from the pope a tithe levied on the clergy, the proceeds of which he kept for his own use; he also confiscated the property of the Lombard bankers who had been invited to France by his father at a time of financial crisis. The history of the assemblies summoned by Charles IV. is obscure, but in 1326, on the outbreak of war with England, an

assembly of prelates and barons met at Meaux. Commissioners were afterwards despatched to the provinces to state the position of affairs and to receive complaints. The king justified his failure to summon the estates on the ground of the expense incurred by provincial deputies.

Charles IV. maintained excellent relations with Pope John XXII., who made overtures to him, indirectly, offering his support in case of his candidature for the imperial crown. He tried to form a party in Italy in support of the pope against the emperor Louis IV. of Bavaria, but failed. A treaty with the English which secured the district of Agenais for France was followed by a feudal war in Guienne. Isabella, Charles's sister and the wife of Edward II., was sent to France to negotiate, and with her brother's help arranged the final conspiracy against her husband. Charles's first wife was Blanche, daughter of Otto IV., count of Burgundy. In May 1314, by order of King Philip IV., she was arrested and imprisoned in the Château-Gaillard with her sister-in-law Marguerite, daughter of Robert II., duke of Burgundy, and wife of Louis Hutin, on a charge of adultery. Tradition has involved and obscured the story, which is the origin of the legend of the Tour de Nesle made famous by the drama of A. Dumas the elder. Blanche died in 1326. In 1322, freed from his first marriage, by papal decree on the ground of kinship, Charles married his cousin Mary of Luxemburg, daughter of the emperor Henry VII., and upon her death, two years later, Jeanne, daughter of Louis, count of Evreux. Charles IV. died at Vincennes on Feb. 1, 1328. He left no issue by his first two wives to succeed him, and daughters only by Jeanne of Evreux. He was the last of the direct line of Capetians.

CHARLES V. (1337-1380), king of France, called **THE WISE**, was born at the château of Vincennes, on Jan. 21, 1337, the son of John II. and Bonne of Luxemburg. In 1349 he became dauphin of the Viennois by purchase from Humbert II. and in 1355 he was created duke of Normandy. After the battle of Poitiers (1356) where his father was taken prisoner by the English, he arranged for the government of Normandy, and proceeded to Paris, where he took the title of lieutenant of the kingdom. During the years of John II.'s imprisonment in England, Charles was virtually king of France. He summoned the States-General of northern France (Langue d'oïl) to Paris in Oct. 1356 to obtain men and money to carry on the war. But under the leadership of Étienne Marcel, provost of the Parisian merchants and president of the third estate, and Robert le Coq, bishop of Laon, president of the clergy, a partisan of Charles of Navarre, the states refused any "aid" except on conditions which Charles declined to accept. They demanded the dismissal of a number of the royal ministers; the establishment of a commission elected from the three estates to regulate the dauphin's administration, and of another board to act as council of war; also the release of Charles the Bad, king of Navarre, who had been imprisoned by King John. The estates of Languedoc, summoned to Toulouse, also made protests against misgovernment, but they agreed to raise a war-levy on terms to which the dauphin acceded. Charles sought the alliance of his uncle, the emperor Charles IV., to whom he did homage at Metz as dauphin of the Viennois, and he was also made imperial vicar of Dauphiné, thus acknowledging the imperial jurisdiction. But he gained small material advantage from these proceedings. The States-General were again convoked in Feb. 1357. Their demands were more moderate than in the preceding year, but they nominated members to replace certain obnoxious persons on the royal council, demanded the right to assemble without the royal summons, and certain administrative reforms. In return they promised to raise and finance an army of 30,000 men, but the money—a tithe levied on the annual reve-

nues of the clergy and nobility—voted for this object was not to pass through the dauphin's hands. Charles appeared to consent, but the agreement was annulled by letters from King John, who announced at the same time the conclusion of a two years' truce, and the reformers failed to secure their ends. Charles had escaped from their power by leaving Paris, but he returned for a new meeting of the estates in the autumn of 1357.

Meanwhile, Charles of Navarre had been released by his partisans, and allying himself with Marcel had become a popular hero in Paris. The dauphin was obliged to receive him and to undergo an apparent reconciliation. In Paris Étienne Marcel was supreme. He forced his way into the dauphin's palace (Feb. 1358), and Charles's servant, Jean de Confians, marshal of Champagne, and Robert de Clermont, marshal of Normandy, were murdered before his eyes. Charles was powerless openly to resent these outrages, but he obtained from the provincial assemblies the money refused him by the States-General, and deferred his vengeance until the dissensions of his enemies should offer him an opportunity. Charles of Navarre, now in league with the English and master of lower Normandy and of the approaches to Paris, returned to the immediate neighbourhood of the city, and Marcel found himself driven to avowed co-operation with the dauphin's enemies, the English, and the Navarrese. Charles had been compelled in March to take the title of regent to prevent the possibility of further intervention from King John. In defiance of a recent ordinance prohibiting provincial assemblies, he presided over the estates of Picardy and Artois, and then over those of Champagne. The States-General of 1358 were summoned to Compiègne instead of Paris, and granted a large aid.

The condition of northern France was rendered more desperate by the outbreak (May–June 1358) of the peasant revolt known as the Jacquerie, which was repressed with a ferocity far exceeding the excesses of the rebels. Within the walls of Paris, Jean Maillart had formed a royalist party; Marcel was assassinated (July 31, 1358), and the dauphin entered Paris in the following month. A reaction in Charles's favour had set in, and from the estates of 1359 he regained the authority he had lost. They supported him in repudiating the Treaty of London (1359), which King John had signed in anxiety for his personal freedom, and voted money unconditionally for the continuation of the war. From this time the estates were only once convoked by Charles, who contented himself thenceforward by appeals to the assembly of notables or to the provincial bodies. Charles of Navarre was now at open war with the regent; Edward III. landed at Calais in October; and a great part of the country was exposed to double depredations from the English and the Navarrese troops. In the scarcity of money Charles had recourse to the debasement of the coinage, which suffered no less than 22 variations in the two years before the Treaty of Brétigny. This disastrous financial expedient was made good later, the coinage being established on a firm basis during the last 16 years of Charles's reign in accordance with the principles of Nicolas Oresme. On the conclusion of peace, King John was restored to France, but being unable to raise his ransom, he returned in 1364 to England, where he died in April, leaving the Crown to Charles, who was crowned at Reims on May 19.

The new king found an able servant in Bertrand du Guesclin, who won a victory over the Navarrese troops at Cocherel and took prisoner their best general, Jean de Gailli, captal de Buch. The establishment of Charles's brother, Philip the Bold, in the duchy of Burgundy, though it constituted in the event a serious menace to the monarchy, put an end to the king of Navarre's ambitions in that direction. A treaty of peace between the two kings was signed in 1365, by which Charles of Navarre gave up Mantes, Meulan and the county of Longueville in exchange for Montpellier. Negotiations were renewed in 1370 when Charles of Navarre did homage for his French possessions, though he was then considering an offensive and defensive alliance with Edward III. Du Guesclin undertook to free France from the depredations of the "free companies," mercenary soldiers put out of employment by the cessation of the war. An attempt to send them on a crusade against the Turks failed and Du Guesclin led them to Spain to put

Henry of Trastamara on the throne of Castile. By the marriage of his brother, Philip the Bold with Margaret of Flanders, Charles detached the Flemings from the English alliance, and as soon as he had restored something like order in the internal affairs of the kingdom, he provoked a quarrel with the English.

The text of the Treaty of Brétigny presented technical difficulties of which Charles availed himself. The English power in Guienne was weakened by the disastrous Spanish expedition of the Black Prince, whom Charles summoned before the *parlement* of Paris in Jan. 1369 to answer the charges preferred against him by his subjects, thus expressly repudiating the English supremacy in Guienne. War was renewed in May after a meeting of the States-General. Between 1371 and 1373 Poitou and Saintonge were reconquered by Du Guesclin, and soon the English had to abandon all their territory north of the Garonne. John IV. of Brittany (Jean de Montfort) had won his duchy with English help by the defeat of Charles of Blois, the French nominee at Auray in 1364. His sympathies remained English, but he was now (1373) obliged to take refuge in England, and later in Flanders, while the English only retained a footing in two or three coast towns. Charles's generals knew that their general levies were no match for the English men-at-arms in a pitched battle; they contented themselves with defensive and guerrilla tactics. The towns were defended, and the English left to do as they would in the countryside. There they could not maintain themselves; they gradually retreated until in 1380 only Bayonne, Bordeaux, Brest and Calais were still in English hands.

Charles had in 1378 obtained proof of Charles of Navarre's treasonable designs. He seized the Norman towns held by the Navarrese, while Henry of Trastamara invaded Navarre, and imposed conditions of peace which rendered his lifelong enemy at last powerless. A premature attempt to amalgamate the duchy of Brittany with the French Crown failed. Charles summoned the duke to Paris in 1378, and on his non-appearance committed one of his rare errors of policy by confiscating his duchy. But the Bretons rose to defend their independence, and recalled their duke. The matter was still unsettled when Charles died at Vincennes on Sept. 16th, 1380. His health, always delicate, had been further weakened, according to popular report, by a slow poison prepared for him by the king of Navarre. His wife, Jeanne of Bourbon, died in 1378, and the succession devolved on their elder son Charles, a boy of twelve. Their younger son was Louis, duke of Orleans.

Personally Charles was no soldier. He owed the signal successes of his reign partly to his skilful choice of advisers and administrators, to his chancellors Jean and Guillaume de Dormans and Pierre d'Orgemont, to Hugues Aubriot, provost of Paris, Bureau de la Rivière and others; partly to a singular coolness and subtlety in the exercise of a not over-scrupulous diplomacy, which made him a dangerous enemy. He had learnt prudence and self-restraint in the troubled times of the regency, and did not lose his moderation in success. He modelled his private life on that of his predecessor, St. Louis, but was no fanatic in religion, for he refused his support to the violent methods of the Inquisition in southern France, and allowed the Jews to return to the country, at the same time confirming their privileges. His support of the schismatic pope Clement VII. at Avignon was doubtless due to political considerations, as favouring the independence of the Gallican Church.

Charles V. was a student of astrology, medicine, law and philosophy and collected a large and valuable library at the Louvre, which became the nucleus of the great *Bibliothèque Royale*. He gathered round him a group of distinguished writers and thinkers, among whom were Raoul de Presles, Philippe de Mézières, Nicolas Oresme and others. The ideas of these men were applied by him to the practical work of administration, though he confined himself chiefly to the consolidation and improvement of existing institutions. The power of the nobility was lessened by restrictions which, without prohibiting private wars, made them practically impossible. The feudal fortresses were regularly inspected by the central authority, many of them were demolished on the pretext that they might serve as vantage points for the English invaders,

and the nobles themselves became in many cases paid officers of the king. The feudal nobility was further weakened by the accession to the *noblesse* of many townsmen. Further, Charles reserved to the Crown the right of giving charters, of coining money; in fact he deprived the great nobles of many sovereign rights hitherto exercised by them. Charles made the *parlement* of Paris a permanent instead of a temporary body, and established it in the former palace of St. Louis, which became the Palais de Justice. He strengthened the Crown itself by substituting a fixed revenue to princes and princesses of the royal house for the apanages which had led to civil strife in former reigns. He tried to free industry by declaring that every competent workman was free to practise his trade outside the guild if he wished, but custom was too strong, and the guilds retained their monopoly for centuries later. He established indirect taxes on objects of consumption so as to bring all classes under contribution; and he secured the payment of the *gabelle* or salt-tax on a firm basis. Under Charles V. the system of royal commissioners for the collection of the revenue took shape, and the *Cour des aides* was definitely established as a court of appeal in taxation cases. He established a merchant marine and a formidable navy, which under Jean de Vienne threatened the English coast between 1377 and 1380. The States-General were silenced and the royal prerogative increased; the royal domains were extended, and the wealth of the Crown was augmented; additions were made to the revenue by the sale of municipal charters and patents; and taxation became heavier, since Charles set no limits to the gratification of his tastes, either in the collection of jewels and precious objects, of books, or of his love of building, examples of which are the renovation of the Louvre and the erection of the palace of Saint Paul in Paris.

(1890); C. Benoist, *La Politique du roi Charles V.* (1874); R. Delachanel, *Histoire de Charles V.* (1908).

CHARLES VI. (1368-1422), king of France, son of Charles V. and Jeanne of Bourbon, was born in Paris on Dec. 3, 1368. He received the apanage of Dauphiné at his birth, and was thus the first of the princes of France to bear the title of dauphin from infancy. Charles V. entrusted his education to Philippe de Mézières, and fixed his majority at 14. He succeeded to the throne in 1380 at the age of 12, and the royal authority was divided between his paternal uncles, Louis, duke of Anjou, John, duke of Berry, Philip the Bold, duke of Burgundy, and his mother's brother, Louis II., duke of Bourbon. Considerable discontent existed in the south of France at the time of the death of Charles V., and when the duke of Anjou re-imposed certain taxes which the late king had remitted at the end of his reign there were revolts at Puy and Montpellier. Paris, Rouen, the cities of Flanders, with Amiens, Orleans, Reims and other French towns, also rose (1382) in revolt against their masters. (For the regency of Louis of Anjou, see FRANCE: *History*.) Charles VI. marched to the help of the count of Flanders against the insurgents headed by Philip van Artevelde, and gained a complete victory at Roosebeke (Nov. 27, 1382). Strengthened by this success the king, on his return to Paris in the following January, exacted vengeance on the citizens by fines, executions and the suppression of the privileges of the city. The help sent by the English to the Flemish cities resulted in a second Flemish campaign. In 1385 Jean de Vienne made an unsuccessful descent on the Scottish coast, and Charles equipped a fleet at Sluys for the invasion of England, but a series of delays ended in the destruction of the ships by the English.

In 1385 Charles VI. married Elizabeth, daughter of Stephen II., duke of Bavaria, her name being gallicized as Isabeau. Three years later, with the help of his brother, Louis of Orleans, duke of Touraine, he threw off the tutelage of his uncles, whom he replaced by Bureau de la Rivière and others among his father's

counsellors, nicknamed by the royal princes the *marmousets* because of their humble origin. Two years later he deprived the duke of Berry of the government of Languedoc. The opening years of Charles VI.'s effective rule promised well, but excess in gaiety of all kinds undermined his constitution, and in 1392 he had an attack of madness at Le Mans, when on his way to Brittany to force from John V. the surrender of his cousin Pierre de Craon, who had tried to assassinate the constable Olivier de Clisson in the streets of Paris. Other attacks followed, and it became evident that Charles was unable permanently to sustain the royal authority. Clisson, Bureau de la Rivière, Jean de Mercier, and the other *marmousets* were driven from office, and the royal dukes regained their power. The rivalries between the most powerful of these (the duke of Burgundy, who during the king's attacks of madness practically ruled the country, and the duke of Orleans) were a constant menace to order.

In 1396 peace with England seemed assured by the marriage of Richard II. with Charles VI.'s daughter Isabella, but the Lancastrian revolution of 1399 destroyed the diplomatic advantages gained by this union. In France the country was disturbed by the papal schism. At an assembly of the clergy held in Paris in 1398 it was resolved to refuse to recognize the authority of Benedict XIII., who succeeded Clement VII. as schismatic pope at Avignon. The question became a party one; Benedict was supported by Louis of Orleans, while Philip the Bold and the university of Paris opposed him. Obedience to Benedict's authority was resumed in 1403, only to be withdrawn again in 1408, when the king declared himself the guardian and protector of the French church, which was indeed for a time self-governing. Edicts further extending the royal power in ecclesiastical affairs were even issued in 1418, after the schism was at an end.

The king's intelligence became yearly feebler, and in 1404 on the death of Philip the Bold the influence of the duke of Orleans increased. Queen Isabeau, who had generally supported the Burgundian party, was now practically separated from her husband, and was replaced by a young Burgundian lady, Odette de Champdivers. Isabeau of Bavaria was freely accused of intrigue with the duke of Orleans. The relations between John the Fearless and the duke of Orleans became more embittered, and on Nov. 23, 1407, Orleans was murdered in the streets of Paris at the instigation of his rival. The young duke Charles of Orleans formed alliances with the dukes of Berry, Bourbon and Brittany, and others who formed the party known as the Armagnacs (see ARMAGNAC), against the Burgundians who had gained the upper hand in the royal council. In 1411 John the Fearless contracted an alliance with Henry IV. of England, and civil war began in the autumn, but in 1412 the Armagnacs in their turn sought English aid, and, by promising the sovereignty of Aquitaine to the English king, gave John the opportunity of posing as defender of France. In Paris the Burgundians were hand in hand with the corporation of the butchers, who were the leaders of the Parisian populace. The malcontents, who took their name from one of their number, Caboché, penetrated into the palace of the dauphin Louis, and demanded the surrender of the unpopular members of his household. A royal ordinance, promising reforms in administration, was promulgated on May 27, 1413, and some of the royal advisers were executed. The king and the dauphin, powerless in the hands of Duke John and the Parisians, appealed secretly to the Armagnac princes for deliverance. They entered Paris in September; the ordinance extracted by the Cabochiens was rescinded, and many of the insurgents were banished from the city.

In the next year Henry V. of England, after concluding an alliance with Burgundy, resumed the pretensions of Edward III. to the crown of France, and in 1415 followed the disastrous battle of Agincourt. The two elder sons of Charles VI., Louis, duke of Guienne, and John, duke of Touraine, died in 1415 and 1417, and Charles, count of Ponthieu, became heir apparent. Paris was governed by Bernard of Armagnac, constable of France, who expelled all suspected of Burgundian sympathies and treated Paris like a conquered city. Queen Isabeau was imprisoned at Tours, but escaped to Burgundy. The capture of Paris by the Burgundians on May 29, 1418, was followed by a series of horrible

massacres of the Armagnacs; and in July Duke John and Isabeau, who assumed the title of regent, entered Paris. Meanwhile Henry V. had completed the conquest of Normandy. The murder of John the Fearless in 1419 under the eyes of the dauphin Charles threw the Burgundians definitely into the arms of the English, and his successor Philip the Good, in concert with Queen Isabeau, concluded (1420) the treaty of Troyes with Henry V., who became master of France. Charles VI. had long been of no account in the government, and the state of neglect in which he existed at Senlis induced Henry V. to undertake the re-organization of his household. He came to Paris in Sept. 1422, and died on Oct. 21.

BIBLIOGRAPHY.—The chief authorities for the reign of Charles VI. are: *Chronica Caroli VI.*, written by a monk of Saint Denis, commissioned officially to write the history of his time, ed. by C. Bellaguet with a French trans. (6 vols. 1839–52); Jean Juvénal des Ursins, *Chronique*, printed by D. Godefroy in *Histoire de Charles VI.* (1653), chiefly an abridgment of the monk of St. Denis's narrative; a fragment of the *Grandes Chroniques de Saint Denis* covering the years 1381–83 (ed. J. Pichon, 1864); corres. of Charles VI. printed by Champollion-Figeac in *Lettres de rois*, vol. ii.; *Choix de pièces inédites rel. au règne de Charles VI.* (2 vols. 1863–64), ed. by L. Douët d'Arq for the Société de l'Histoire de France; J. Froissart, *Chroniques*; Enguerrand de Monstrelet, *Chroniques*, covering the first half of the 15th century (Eng. trans. 4 vols. 1809); *Chronique des quatre premiers Valois*, by an unknown author, ed. S. Luce (1862). See also E. Lavisse, *Hist. de France*, iv. 267 seq.; E. Petit, "Séjours de Charles VI." *Bull. du com. des travaux hist.* (1893); Vallet de Virville, "Isabeau de Bavière," *Revue Française* (1858–59); M. Thibaut, *Isabeau de Bavière* (1903); F. Funck-Brentano, *Le Moyen Age* (Eng. Trans. *The Middle Ages*), ch. xix. and bibl. there given (1922).

CHARLES VII. (1403–1461), king of France, fifth son of Charles VI. and Isabeau of Bavaria, was born in Paris on Feb. 22, 1403. The count of Ponthieu, as he was called in his boyhood, was betrothed in 1413 to Mary of Anjou, daughter of Louis II., duke of Anjou and king of Sicily, and spent the next two years at the Angevin court. He received the duchy of Touraine in 1416, and in the next year the death of his brother John made him dauphin of France. He became lieutenant-general of the kingdom in 1417. He became regent in Dec. 1418, but his authority in northern France was paralysed in 1419 by the murder of John the Fearless, duke of Burgundy, in his presence at Montreuil. Although the deed was not apparently premeditated, as the English and Burgundians declared, it ruined Charles's cause for the time. He was disinherited by the treaty of Troyes in 1420, and at the time of his father's death in 1422 had retired to Mehun-sur-Yèvre, near Bourges, which had been the nominal seat of government since 1418. He was recognized as king in Touraine, Berry and Poitou, in Languedoc and other provinces of southern France; but the English power in the north was presently increased by the provinces of Champagne and Maine, as the result of the victories of Crevant (1423) and Verneuil (1424). The Armagnac administrators who had been driven out of Paris by the duke of Bedford gathered round the young king, nicknamed the "king of Bourges," but he was weak in body and mind, and was under the domination of Jean Louvet and Tanguy du Chastel, the instigators of the murder of John the Fearless, and other discredited partisans. The power of these favourites was shaken by the influence of the queen's mother, Yolande of Aragon, duchess of Anjou. She sought the alliance of John V., duke of Brittany, who, however, vacillated throughout his life between the English and French alliance, concerned chiefly to maintain the independence of his duchy. His brother, Arthur of Brittany, earl of Richmond (comte de Richemont), was reconciled with the king, and became constable in 1425, with the avowed intention of making peace between Charles VII. and the duke of Burgundy. Richemont caused the assassination of Charles's favourites Pierre de Giac and Le Camus de Beaulieu, and imposed one of his own choosing, Georges de la Trémoille, an adventurer who rapidly usurped the constable's power. For five years (1427–32) a private war between these two exhausted the Armagnac forces, and central France returned to anarchy.

Meanwhile Bedford had established settled government throughout the north of France, and in 1428 he advanced to the siege of Orleans. For the movement which was to lead to the deliverance of France from the English invaders, see JOAN OF ARC. The

siege of Orleans was raised by her efforts on May 8, 1429, and two months later Charles VII. was crowned at Reims. But the court put every difficulty in the way of her military career, and received the news of her capture before Compiègne (1430) with indifference. No measures were taken for her deliverance or her ransom, and Normandy and the Isle of France remained in English hands. Fifteen years of anarchy and civil war intervened before peace was restored. The duke of Bedford died in 1435, and in the same year Philip the Good of Burgundy concluded a treaty with Charles VII. at Arras, after fruitless negotiations for an English treaty. From this time Charles's policy was strengthened. La Trémoille had been assassinated in 1433 by the constable's orders, with the connivance of Yolande of Aragon. For his former favourites were substituted energetic advisers, his brother-in-law Charles of Anjou, Dunois (the famous bastard of Orleans), Pierre de Brézé, Richemont and others. Richemont entered Paris on April 13, 1436, and in the next five years the finance of the country was re-established on a settled basis. Charles himself commanded the troops who captured Pontoise in 1441, and in 1442 he made a successful expedition in the south.

Meanwhile the princes of the blood and the great nobles made a formidable league against the crown in 1440 which included Charles I., duke of Bourbon, John II., duke of Alençon, John IV. of Armagnac, and the dauphin, afterwards Louis XI. The revolt broke out in Poitou in 1440 and was known as the Praguerie. Charles VII. repressed the rising, and finally bought over the rebel nobles individually by considerable concessions. In 1444 a truce was concluded with England at Tours, and Charles proceeded to organize a regular army. The central authority was gradually made effective. Domestic troubles in their own country weakened the English in France. The conquest of Normandy was completed by the battle of Formigny (April 15, 1450). Guienne was conquered in 1451 by Dunois, but not subdued, and another expedition was necessary in 1453, when Talbot was defeated and slain at Castillon. Meanwhile in 1450 Charles VII. had resolved on the rehabilitation of Joan of Arc. This was granted in 1456 by the Holy See. The only foothold retained by the English on French ground was Calais. The change which made Charles take an active part in public affairs is said to have been largely due to the influence of Agnes Sorel, who became his mistress in 1444 and died in 1450. She was the first to play a public and political rôle as mistress of a king of France. Pierre de Brézé, who had had a large share in the repression of the Praguerie, obtained through her a dominating influence over the king. Charles and René of Anjou retired from court, and the greater part of the members of the king's council were drawn from the bourgeois classes. The most famous of all these was Jacques Coeur (*q.v.*). It was by the zeal of these councillors that Charles obtained the surname of "The Well-Served."

Charles VII. continued his father's general policy in church matters. He desired to preserve as far as possible the liberties of the Gallican church. With the council of Constance (1414–18) the great schism was practically healed. Charles, while careful to protest against its renewal, supported the anti-papal contentions of the French members of the council of Basle (1431–49), and in 1438 he promulgated the Pragmatic Sanction at Bourges, by which the patronage of ecclesiastical benefices was removed from the Holy See, while certain interventions of the royal power were admitted. Bishops and abbots were to be elected, in accordance with ancient custom, by their clergy. After the English had evacuated French territory Charles still had to cope with feudal revolt, and with the hostility of the dauphin, who was in open revolt in 1446, and for the next ten years ruled like an independent sovereign in Dauphiné. He took refuge in 1457 with Charles's most formidable enemy, Philip of Burgundy. Charles VII. nevertheless found means to prevent Philip from attaining his ambitions in Lorraine and in Germany. But the dauphin succeeded in embarrassing his father's policy at home and abroad, and had his own party in the court itself. Charles VII. died at Mehun-sur-Yèvre on July 22, 1461. He believed that he was poisoned by his son, who cannot, however, be accused of anything more than an eager expectation of his death.

BIBLIOGRAPHY.—The history of the reign of Charles VII. has been written by two modern historians—Vallet de Virville, *Histoire de Charles VII. . . et de son époque* (3 vols., 1862–65), and G. du Fresne de Beaucourt, *Hist. de Charles VII.* (6 vols., 1881–91), which gives a detailed bibliography. There is abundant contemporary material. The herald, Jacques le Bouvier or Berry (b. 1386), whose *Chroniques du feu roi Charles VII.* was first printed in 1528 as the work of Alain Chartier, was an eye-witness of many of the events he described. The *Histoire de Charles VII.* by Jean Chartier, historiographer-royal from 1437 was re-edited by Vallet de Virville (3 vols., 1858–59).

CHARLES VIII. (1470–1498), king of France, was the only son of Louis XI. On the death of Louis XI. in 1483 Charles, a lad of 13, was absolutely incapable of governing. Until 1492 he abandoned the Government to his sister Anne of Beaujeu. In 1491 he married Anne, duchess of Brittany. Urged by his favourite, Étienne de Vesc, he threw off the yoke of the Beaujeus, and at the same time discarded their wise and able policy. He proposed at first to claim the rights of the house of Anjou, to which Louis XI. had succeeded, on the kingdom of Naples, and to use this as a stepping-stone to the capture of Constantinople from the Turks and his own coronation as emperor of the East. He sacrificed everything to this adventurous policy, signed disastrous treaties to keep his hands free, and set out for Italy in 1494. On May 12, 1495, he entered Naples in great pomp, clothed in the imperial insignia. A general coalition was, however, formed against him, and he was forced to return to France. He was preparing a fresh expedition when he died on April 8, 1498.

See *Histoire de Charles VIII., roy de France*, by G. de Jaligny, André de la Vigne, etc., edit. Godefroy (1684); C. De Cherrier, *Histoire de Charles VIII.* (1868); H. Fr. Delaborde, *Expédition de Charles VIII. en Italie* (1888); *Anne de Beaujeu, roi de France* (1926). For a complete bibliography see H. Hauser, *Les Sources de l'histoire de France, 1494–1610*, vol. i. (1906); and E. Lavisse, *Histoire de France*, vol. v., part 1., by H. Lemonnier (1903).

CHARLES IX. (1550–1574), king of France, was the third son of Henry II. and Catherine de' Medici. He became king in 1560 by the death of his brother Francis II., but as he was only ten years old the power was in the hands of the queen-mother, Catherine. Charles seems to have been a youth of good parts, but he was left to his whims and to his taste for violent exercises; and the excesses to which he gave himself up ruined his health. Proclaimed of age on Aug. 17, 1563, he submitted docilely to the authority of his mother. In 1570 he was married to Elizabeth of Austria, daughter of Maximilian II. It was about this time that he dreamed of making a figure in the world. The successes of his brother, the duke of Anjou, at Jarnac and Moncontour had already caused him some jealousy. When Coligny came to court, he received him very warmly, and seemed at first to accept the idea of an intervention in the Netherlands against the Spaniards. For the upshot of this adventure see the article ST. BARTHOLOMEW, MASSACRE OF. Charles was in these circumstances no hypocrite, but weak, hesitating and ill-balanced. The terrible events in which he had played a part transformed his character. He became melancholy, severe and taciturn. Undermined by fever, at the age of 20, he was a haunted man. He died on May 30, 1574. By his mistress, Marie Touchet, he had one son, Charles, duke of Angoulême. Charles IX. had a sincere love of letters, himself practised poetry, was the patron of Ronsard and the poets of the Pleiad, and granted privileges to the first academy founded by Antoine de Baif (afterwards the Académie du Palais). He left a work on hunting, *Traité de la chasse royale*, which was published in 1625, and reprinted in 1859.

Desjardins, *Charles IX., Deux années de règne, 1570–1572* (1873); le comte de la Ferrière, *Le XVI^e siècle et les Valois* (1879); J. H. Mariéjol, "La Réforme et la Ligue," in vol. v. of the *Histoire de France* (ed. E. Lavisse, 1904), which contains a bibliography for the reign; L. Batifol, *Le Siècle de la Renaissance* (1909, Eng. trans. 1916); L. Romier, *Catholiques et Huguenots à la cour de Charles IX.* (1924). See also CATHERINE DE' MEDICIS, COLIGNY, etc.

CHARLES X. (1757–1836), king of France from 1824 to 1830, was the fourth child of the dauphin Louis, son of Louis XV. and of Marie Josephe of Saxony. He was known before his acces-

sion as Charles Philippe, count of Artois. At the age of 16 he married Marie Thérèse of Savoy, sister-in-law of his brother, the count of Provence (Louis XVIII.). His youth was passed in scandalous dissipation, which drew upon himself and his coterie the detestation of the people of Paris. Prior to the revolution he took only a minor part in politics, but when it broke out he soon became, with the queen, the chief of the reactionary party at court. In July 1789 he left France and became leader of the émigrés. In 1795 he attempted to aid the royalist rising of La Vendée, landing at the island of Yeu. But he refused to advance farther and returned to England, settling first in London, then in Holyrood palace at Edinburgh and afterwards at Hartwell. There he remained until 1813, returning to France in Feb. 1814, and entering Paris in April, in the track of the Allies.

During the reign of his brother, Louis XVIII., he was the leader of the ultra-royalists, the party of extreme reaction. On succeeding to the throne in Sept. 1824 he won a passing popularity. But his coronation at Reims, with all the gorgeous ceremonial of the old régime, proclaimed his intention of ruling as the Most Christian King, by divine right. It was soon apparent that the weight of the crown would be consistently thrown into the scale of the reactionary forces. The émigrés were awarded a milliard as compensation for their confiscated lands; and Gallicans and Liberals alike were offended by measures which threw increased power into the hands of the Jesuits and Ultramontanes. In a few months there were disquieting signs of the growing unpopularity of the king. The royal princesses were insulted in the streets; and on April 29, 1825 Charles, when reviewing the National Guard, was met with cries from the ranks of "Down with the ministers!" His reply was, next day, a decree disbanding the citizen army.

In 1829 Charles consented unwillingly to try a policy of compromise. Villèle's successor was the vicomte de Martignac, who took Decazes for his model; and in the speech from the throne Charles declared that the happiness of France depended on "the sincere union of the royal authority with the liberties consecrated by the charter." But Charles had none of the patience and common sense which had enabled Louis XVIII. to play with decency the part of a constitutional king. "I would rather hew wood," he exclaimed, "than be a king under the conditions of the king of England;" and when the Liberal opposition obstructed all the measures proposed by a ministry not selected from the parliamentary majority, he lost patience. "I told you," he said, "that there was no coming to terms with these men." Martignac was dismissed; and Prince Jules de Polignac, the very incarnation of clericalism and reaction, was called to the helm of state.

A formidable agitation sprang up, which only served to make the king more obstinate. In opening the session of 1830 he declared that he would "find the power" to overcome the obstacles placed in his path by "culpable manoeuvres." The reply of the chambers was a protest against "the unjust distrust of the sentiment and reason of France"; whereupon they were first prorogued, and on May 16 dissolved. The result of the new elections was a large increase in the opposition; and Charles, on the advice of his ministers, determined on a virtual suspension of the constitution. On July 25 were issued the famous "four ordinances" which were the immediate cause of the revolution.

With singular fatuity Charles had taken no precautions in view of a violent outbreak. Marshal Marmont, who commanded the scattered troops in Paris, had received no orders, beyond a jesting command from the duke of Angoulême to place them under arms "as some windows might be broken." At the beginning of the revolution Charles was at St. Cloud, whence on the news of the fighting he withdrew first to Versailles and then to Rambouillet. On learning of the success of the revolutionaries he abdicated in favour of his grandson, the duke of Bordeaux (comte de Chambord), and appointed Louis Philippe, duke of Orleans, lieutenant-general of the kingdom (July 30). But, on the news of Louis Philippe's acceptance of the crown, he gave up the contest and began a dignified retreat to the sea-coast. Beyond sending a corps of observation to follow his movements, the new government did nothing to arrest his escape. He took ship at Cherbourg for England on Aug. 16. For a time he returned to Holyrood palace

at Edinburgh, which was again placed at his disposal. He died at Göritz, whither he had gone for his health, on Nov. 6, 1836.

The best that can be said of Charles X. is that, if he did not know how to rule, he knew how to cease to rule.

Villeneuve, *Charles X. et Louis XIX. en exil Mémoires inédits* (1889); Imbert de Saint-Amand, *La Cour de Charles X.* (1892).

CHARLES I. (1288-1342), king of Hungary, the son of Charles Martell of Naples, and Clemencia, daughter of the emperor Rudolph, was known as Charles Robert before his enthronement as king of Hungary in 1309. He claimed the Hungarian Crown, as the grandson of Stephen V., under the banner of the pope, and was crowned at Esztergom after the death of the last Arpad, Andrew III. (1301), but was forced the same year to surrender the Crown to Wenceslaus II. of Bohemia (1289-1306), who in 1305 transferred his rights to Duke Otto of Bavaria. Duke Otto was taken prisoner by the Hungarians and Charles was enthroned at Budapest on June 15, 1309, though his installation was not regarded as valid till he was crowned with the sacred crown (which was recovered from the robber barons) at Székesfehérvár on Aug. 27, 1310. After three years of warfare Charles at length put down all the elements of rapine and disorder at Rozgony (June 15, 1312). His foreign policy aimed at the aggrandizement of his family, but Hungary also benefited greatly from it. His most successful achievement was the union with Poland for mutual defence against the Habsburgs and the Czechs, which was accomplished by the Convention of Trencsén (1335), confirmed the same year at the brilliant Congress of Visegrád, where all the princes of Central Europe met to compose their differences. The result of the congress was a combined attack by the Magyars and the Poles upon the emperor Louis and his ally Albert of Austria, which was decided in Charles's favour in 1337. Charles wished to unite the kingdoms of Hungary and Naples under his eldest son Louis, but was frustrated by Venice and the pope, who feared that Hungary might become the dominant Adriatic Power. He was, however, compensated for this disappointment by his compact (1339) with his ally and brother-in-law, Casimir of Poland, whereby it was agreed that Louis should succeed to the throne of Poland on the death of the childless Casimir. Charles was a statesman of the first rank, who not only raised Hungary once more to the rank of a great Power, but enriched and civilized her. In character he was pious, courtly and valiant, popular alike with the nobility and the middle classes, whose increasing welfare he did so much to promote, and much beloved by the clergy. His court was famous throughout Europe as a school of chivalry.

Three sons, Louis, Andrew and Stephen survived him. He died on July 16, 1342, and was laid beside the high altar at Székesfehérvár, the ancient burial place of the Arpads.

See Béla Kerékgyártó, *The Hungarian Royal Court under the House of Anjou* (Hung.) (Budapest, 1881); *Rationes Collectorum Pontif. in Hungaria* (Budapest, 1887); *Diplomas of the Angevin Period*, edit. Imre Nagy (Hung. and Lat.) vols. i.-iii. (Budapest, 1878, etc.).

CHARLES I. (1226-1285), king of Naples and Sicily and count of Anjou, was the seventh child of Louis VIII. of France and Blanche of Castile. Louis died a few months after Charles's birth and was succeeded by his son Louis IX. (St. Louis), and on the death in 1232 of the third son, John, count of Anjou and Maine, those fiefs were conferred on Charles. In 1246 he married Beatrice, daughter and heiress of Raymond Bérenger V., the last count of Provence, and after defeating James I. of Aragon and other rivals with the help of his brother, the French king, he took possession of his new county. In 1248 he accompanied Louis in the crusade to Egypt, but on the defeat of the Crusaders he was taken prisoner with his brother. Shortly afterwards he was ransomed, and returned to Provence in 1250. Charles's ambition aimed at wider fields, and he extended his influence by the subjugation of Marseille in 1257, and two years later several com-

munes of Piedmont recognized his suzerainty. In 1262 Pope Urban IV. determined to destroy the power of the Hohenstaufen in Italy, and offered the kingdoms of Naples and Sicily, in consideration of a yearly tribute, to Charles of Anjou. After long negotiations he accepted the Sicilian and Neapolitan crowns, and in 1264 he sent a first expedition of Provençals to Italy; he also collected a large army and navy in Provence and France with the help of King Louis, and by an alliance with the cities of Lombardy was able to send part of his force overland. Pope Clement IV. confirmed the Sicilian agreement on conditions even more favourable to Charles, who sailed in 1265, and conferred on the expedition all the privileges of a crusade. After narrowly escaping capture by Manfred's fleet he reached Rome safely, where he was crowned king of the Two Sicilies. The land army arrived soon afterwards, and on Feb. 26, 1266, Charles encountered his rival Manfred the bastard of the emperor Frederick II., at Benevento (q.v.), where after a hard-fought battle Manfred was defeated and killed, and the whole kingdom was soon in Charles's possession. Then Conradin, Frederick's grandson and last legitimate descendant of the Hohenstaufen, came into Italy, where he found many partisans among the Ghibellines of Lombardy and Tuscany, and among Manfred's former adherents in the south. He was totally defeated by Charles at Tagliacozzo (Aug. 23, 1268); taken prisoner, he was tried as a rebel and executed at Naples.

Charles was now one of the most powerful sovereigns of Europe, for besides ruling over Provence and Anjou and the kingdom of the Two Sicilies, he was imperial vicar of Tuscany, lord of many cities of Lombardy and Piedmont, and as the pope's favourite practically arbiter of the papal states, especially during the interregnum between the death of Clement IV. (1268) and the election of Gregory X. (1272). In 1272 he took part with Louis IX. in a crusade to north Africa. The election of Rudolph of Habsburg as German king, and that of Nicholas III. to the Holy See (1277), diminished Charles's power, for the new pope set himself to compose the difference between Guelphs and Ghibellines in the Italian cities, but at his death Charles secured the election of his henchman Martin IV. (1281), who recommenced persecuting the Ghibellines. But the cruelty of the French rulers of Sicily provoked in 1282 the rebellion known as the Sicilian Vespers (see VESPERS, SICILIAN). Charles determined to subjugate the island and sailed with his fleet for Messina. The city held out until Peter III. of Aragon arrived in Sicily, and a Sicilian-Catalan fleet under the Calabrese admiral, Ruggiero di Lauria, completely destroyed that of Charles. In May 1284 Ruggiero di Lauria appeared before Naples and destroyed another Angevin fleet commanded by Charles's son, who was taken prisoner. Charles came to Naples with a new fleet from Provence, and was preparing to invade Sicily again, when he died at Foggia on Jan. 7, 1285. An extremely able soldier and a skilful statesman, his inordinate ambition and his cruelty created enemies on all sides, and led to the collapse of the edifice of dominion which he had raised.

CHARLES II. (1250-1309), king of Naples and Sicily, son of Charles I., had been captured by Ruggiero di Lauria in the naval battle at Naples in 1284, and when his father died he was still a prisoner in the hands of Peter of Aragon. In 1288 Charles was liberated on the understanding that he was to retain Naples alone, Sicily being left to the Aragonese, and to induce his cousin Charles of Valois to renounce the kingdom of Aragon given to him by Pope Martin IV. He went to Rieti, where the new pope Nicholas IV. immediately absolved him from all the conditions he had sworn to observe, crowned him king of the Two Sicilies (1289), and excommunicated Alphonso, while Charles of Valois, in alliance with Castile, prepared to take possession of Aragon. Alphonso III., the Aragonese king, being hard pressed, had to promise to withdraw the troops he had sent to help his brother James in Sicily, to renounce all rights over the island, and pay a tribute to the Holy See. But Alphonso died childless in 1291 before the treaty could be carried out, and James took possession of Aragon, leaving the government of Sicily to the third brother Frederick. The new pope Boniface VIII., elected in 1294 at Naples under the auspices of King Charles, mediated between the latter

and James, and a most dishonourable treaty was signed. An attempt was made to bribe Frederick into consenting to the arrangement, but being backed up by his people he refused, and was afterwards crowned king of Sicily. The ensuing war was fought with great fury and peace was not made until 1302 at Caltabellotta, Charles II. giving up all rights to Sicily and agreeing to the marriage of his daughter Leonora to King Frederick; the treaty was ratified by the pope in 1303. Charles died in Aug. 1309, and was succeeded by his son Robert.

BIBLIOGRAPHY.—A. de Saint-Priest, *Histoire de la conquête de Naples par Charles d'Anjou* (4 vols., 1847-49); S. de Sismondi, in *Histoire des républiques italiennes*, vol. ii. (Brussels, 1838), gives a good general sketch; R. Sternfeld, *Karl von Anjou als Graf von Provence* (1888); Charles's connection with north Italy is dealt with in Merkel's *La Dominazione di Carlo d'Angiò in Piemonte e in Lombardia* (Turin, 1891), while the R. Deputazione di Storia Patria Toscana has recently published a *Codice diplomatico delle relazioni di Carlo d'Angiò con la Toscana*; by Durrien, *Archives angevines de Naples* (Toulouse, 1866-1867). M. Amari's *La Guerra del Vespro Siciliano* (8th ed., Florence, 1876) is a valuable history, but is prejudiced and should be compared with L. Cadier's *Essai sur l'administration du royaume de Sicile sous Charles I et Charles II d'Anjou* (1891, *Bibl. des écoles françaises d'Athènes et de Rome*, fasc. 59), which contains many documents.

CHARLES II. (1332-1387), called THE BAD, king of Navarre and count of Evreux, was a son of Jeanne II., queen of Navarre, by her marriage with Philip, count of Evreux. He succeeded his mother in 1349, and in 1352 married Jeanne, daughter of John II. of France. Trouble soon arose between King John and his son-in-law. The promised dowry had not been paid, and the county of Angoulême, formerly belonging to Jeanne of Navarre, was then in the possession of John's favourite, the constable Charles la Cerda. In Jan. 1354 the constable was assassinated, and John was forced to make a treaty at Mantes and to compensate Charles for the loss of Angoulême by a large grant of lands, chiefly in Normandy. In Normandy, Charles was partly responsible for some unrest, and in April 1356 was seized by the French king at Rouen, remaining in captivity until Nov. 1357, after John became a prisoner in England. Charles was then considered by Étienne Marcel and his party as a suitable rival to the dauphin, afterwards King Charles V. Peace was made, but the dauphin's failure to restore to Charles his confiscated estates led to war, quickly followed by a new treaty, after which Charles took part in suppressing the peasant rising known as the *Jacquerie*. However, in June 1358, he returned to Paris, and became captain-general of the city, which was soon besieged by the dauphin. Charles left Paris just before the murder of Marcel in July and continued his alternate policy of war and peace, until the conclusion of the treaty of Brétigny in May 1360, deprived him of the alliance of the English, and compelled him to make peace with King John. When the duchy of Burgundy became vacant in Nov. 1361, Charles made an unsuccessful claim for it.

In July 1362, in alliance with Pedro the Cruel, king of Castile, he invaded Aragon, soon deserting his new ally for Peter IV., king of Aragon. In turn he made treaties with the kings of Castile and Aragon, until he signed a treaty with Edward of England, and then in 1371 he allied himself with Charles V. of France. He was accused of attempting to poison the king of France and other prominent persons, and of other crimes; his French estates were seized and Cherbourg surrendered. After the death of Charles V., in 1380, the king of Navarre did not interfere in the internal affairs of France. His lands in France were handed over to his eldest son Charles, who governed them with the consent of the new king, Charles VI. Charles died on Jan. 1, 1387, and was succeeded by his eldest son Charles; one of his daughters, Jeanne, became the wife of Henry IV. of England.

See D. F. Secousse, *Mémoires pour servir à l'histoire de Charles II. roi de Navarre* (1755-68); Jean Froissart, *Chroniques*, ed. by S. Luce and G. Raynaud (1869-97); E. Meyer, *Charles II. roi de Navarre et la Normandie au XIV^e siècle* (1898); R. Delachenal, *Premières négociations de Charles le Mauvais avec les Anglais* (1900) and E. Lavisse, *Histoire de France*, t. iv. (1902).

CHARLES III. (1361-1425), called THE NOBLE, king of Navarre and count of Evreux, was the eldest son of Charles II. the Bad (*q.v.*), and was married in 1375 to Leonora, daughter of Henry II., king of Castile. He became king of Navarre in 1387,

and, in contrast to his father's reign, his was a period of peace and order. In 1393 he regained Cherbourg, which had been handed over by Charles II. to Richard II. of England, and in 1403 exchanged it for certain other lands in France. He was created duke of Nemours and made a peer of France. He died at Olite on Sept. 8, 1425. After the death of his two sons in 1402 the king secured his kingdom for his daughter Blanche (d. 1441), who took for her second husband John, afterwards John II., king of Aragon; and the cortes of Navarre swore to recognize Charles (*q.v.*), prince of Viana, her son by this marriage, as king after his mother's death.

CHARLES (KARL EITEL; in Rum. CAROL), king of Rumania (1839-1914), second son of Prince Karl Anton of Hohenzollern-Sigmaringen, was born on April 20, 1839. He was educated at Dresden (1850-1856), and passed through his university course at Bonn. Entering the Prussian army in 1857, he served in the Danish war of 1864, and received instruction in strategy from General von Moltke. He afterwards travelled in France, Italy, Spain and Algeria. He was a captain in the 2nd regiment of Prussian Dragoon Guards when he was elected *hospodar* or prince of Rumania on April 20, 1866, after the compulsory abdication of Prince Alexander John Cuza. Regarded at first with distrust by Turkey, Russia and Austria, he rapidly gained general recognition; but he had to contend for ten years with fierce party struggles between the Conservatives and the Liberals.

During this period, however, Charles displayed great tact in his dealings with both parties, and kept his country in the path of administrative and economic reform, organizing the army, developing the railways, and establishing commercial relations with foreign powers. The sympathy of Rumania with France in the Franco-Prussian War of 1870, and the consequent interruption of certain commercial undertakings, led to a hostile movement against Prince Charles, which, being fostered by Russia, made him resolve to abdicate; and it was with difficulty that he was persuaded to remain. In the Russo-Turkish War of 1877-78 he joined the Russians before Plevna (*q.v.*), and being placed in command of the combined Russian and Rumanian forces, forced Osman Pasha to surrender. As a consequence of the prince's vigorous action the independence of Rumania, which had been proclaimed in May 1877, was confirmed by various treaties in 1878, and recognized by Great Britain, France and Germany in 1880. On March 26, 1881, he was proclaimed king of Rumania, and, with his consort, was crowned on May 22 following. From that time he pursued a successful career in home and foreign policy, and greatly improved the financial and military position of his country; while his appreciation of the fine arts was shown by his formation of an important collection of paintings of all schools in his palaces at Sinaia and Bucharest. For an account of the events of his reign, see BALKAN WARS and RUMANIA. On Nov. 1 1869 he married Princess Elizabeth (*q.v.*), a daughter of Prince Hermann of Wied, widely known under her literary name of "Carmen Sylva." As the only child of the marriage, a daughter, died in 1874, the succession was finally settled upon the king's nephew, Prince Ferdinand of Hohenzollern-Sigmaringen (see FERDINAND I.). He died at the castle of Pelesh, Rumania, on Oct. 10, 1914.

The official life of King Charles, mainly his own composition, *Aus dem Leben König Karls von Rumänien* (Stuttgart, 1894-1900, 4 vols.), deals mainly with political history. See for an account of his domestic life, M. Kremnitz, *König Karl von Rumänien: Ein Lebensbild* (Breslau, 1903).

CHARLES II. (1661-1700), king of Spain, the son of Philip IV. by his second marriage with Maria, daughter of the emperor Ferdinand III., was born on Nov. 11, 1661. Weak, indolent and almost imbecile from his birth, Charles was brought up under the tutelage of his Austrian mother, who was later exiled from court by the younger Don John of Austria, a natural son of Philip IV. In 1679, Charles married Maria Louisa of Orleans, thereby satisfying French interests, which were still more advanced by his acceptance of the Treaty of Ratisbon, June 1684. On the death of the French princess in the stifling atmosphere of the Spanish court, Charles married Maria Ana of Neuberg in

1689, and Austrian interests were again promoted. Always decrepit in mind and body, the king, driven wild by the conflict between his wish to transmit his inheritance to "the illustrious house of Austria," his own kin, and the belief instilled into him by the partisans of the French claimant that only the power of Louis XIV. could avert the dismemberment of the empire, was at last reduced to an abject condition. Under pressure from the cardinal archbishop of Toledo, Portocarrero, he finally made a will in favour of Philip, duke of Anjou, grandson of Louis XIV., thereby ending the inglorious line of the Spanish Habsburgs. He died on Nov. 1, 1700.

See M. de Villars, *Lettres* (1868); P. de Villars, *Mémoires de la Cour d'Espagne* (1893); G. Maura Gamaza, *Carlos II. y su Corte*, 2 vols. (1915). (For a genealogical table of the Spanish Habsburgs, see HABSBERG.)

CHARLES III. (1716–1788), king of Spain, born on Jan. 20, 1716, was the first son of the second marriage of Philip V. with Elizabeth Farnese of Parma. In 1732 he was sent to rule as duke of Parma by right of his mother, and two years later, 1734, made himself master of Naples and Sicily and began there the work of internal reform which he afterwards continued in Spain. On the death of his half-brother Ferdinand VI. he became king of Spain and resigned the Two Sicilies to his third son, Ferdinand.

As king of Spain his foreign policy was disastrous. His strong family feeling and his detestation of England, which was unchecked after the death of his wife, Maria Amelia, daughter of Frederick Augustus II. of Saxony, in 1760, led him into the Family Compact with France. Spain was entangled in the close of the Seven Years' War, to her great loss. In 1779 he was, somewhat reluctantly, led to join France and the American insurgents against England. His internal government was on the whole beneficial to the country. He improved sanitation, suppressed lawlessness, encouraged trade and industry, and constructed roads and canals. Although a sincere Roman Catholic, he consented to the expulsion of the Jesuits from Spain, reduced the number of idle clergy, and rendered the Inquisition ineffectual. When he died on Dec. 14, 1788, Charles, the greatest of the Spanish Bourbons, left the reputation of an enlightened monarch.

BIBLIOGRAPHY.—See M. Danvila y Collado, *Reign of Charles III.* (6 vols.), in the *Historia General de España de la Real Academia de la Historia* (1892, etc.); J. Addison, *Charles the Third of Spain* (1900); F. Rousseau, *Règne de Charles III. d'Espagne* (1907).

CHARLES IV. (1748–1819), king of Spain, second son of Charles III. and his wife Maria Amelia of Saxony, was born on Nov. 11, 1748. The elder brother was set aside as imbecile and epileptic. Charles married Maria Luisa of Parma, his first cousin, who, on his accession to the throne in 1788, directed affairs with the assistance of her lover Godoy (*q.v.*). The king was too slothful to have more than a passive part in the direction of his own Government. If he ever understood that his kingdom was treated as a mere dependence by France, he consoled himself with a belief in his divine right and the sanctity of his person. When he was told that his son Ferdinand was appealing to Napoleon against Godoy, he took the side of the favourite, and when the populace rose at Aranjuez in 1808 he abdicated to save the minister. He took refuge in France, and being imprisoned with his son he was with difficulty restrained from assaulting him. Finally he abdicated in favour of Napoleon and died at Rome on Jan. 20, 1819.

See General Gomez de Arceche (*Historia del Reinado de Carlos IV.*) in the *Historia General de España de la Real Academia de la Historia* (1892, etc.); A. Savine, *L'Abdication de Bayonne*. (1908).

CHARLES IX. (1550–1611), king of Sweden, the youngest son of Gustavus Vasa and Margareto Lejonhufud, was born on Oct. 4, 1550. By his father's will he received the duchy of Södermanland (Sudermania) in 1560. In 1568 he and his brother John led the rebellion against Eric XIV., but when John became king, as John III., the relations between the two brothers were strained. Duke Charles was the centre of the opposition to John's attempts to romanize Sweden on the one hand, and he resisted all the king's efforts to restrict his authority as duke of Södermanland on the other, though in 1587 he was obliged to resign his claim to autonomy within his own duchy. The religious question came to a crisis on the death of John III. in 1592, when

his eldest son, Sigismund, a devoted Catholic who was already king of Poland, succeeded to the throne of Sweden. Duke Charles came forward as the champion of the Protestant majority, who were alarmed lest Sigismund should attempt to re-catholicize Sweden; it was with his assent that they held the famous Synod or "Uppsala-möte" Feb. 1593, which proclaimed Sweden's adherence to the Augsburg Confession; and when Sigismund arrived in Sweden Charles, who had governed jointly with the Estates during his absence, backed by an army, compelled him, before he could be crowned, to guarantee to maintain the Uppsala convention, thereby recognizing that Sweden was essentially a Protestant state. In Aug. 1594 when Sigismund left for Poland, Charles was left in control of affairs, and in 1595 he was elected regent by the *Riksdag* of Söderköping. He ruled firmly, almost despotically. Roman Catholicism was suppressed. In May 1595 the peace of Teusin was concluded with Russia, who recognized Sweden's title to Narva and Estonia. By 1597 however, the country was in a state of civil war. Charles had quarrelled with the council over their refusal to make war on Finland, whose ruler, Klas Fleming, refused to recognize Charles's authority as opposed to that of Sigismund. Sigismund forbade the summoning of the *Riksdag* which supported Charles, and authorized the council to govern alone, but Charles summoned the *Riksdag* when the council was not sitting, and persuaded it to give him all the powers of government. He then sailed to Finland and captured Åbo. Sigismund landed at Kalmar in Sweden with an army, in July 1598, but though large numbers of the nobles flocked to his standards he was regarded as a heretic by the majority of the Swedish nation. Charles defeated him at Stångebro on Sept. 25, 1598, after which he fled for aid to Poland, though he had promised to disband his forces and to abide by the decision of the Estates. He was formally deposed by the *Riksdag* in 1599, and on Feb. 24, 1600, the diet of Linköping declared that he and his posterity had forfeited the Swedish throne, and passing over duke John, the second son of John III., a youth of ten, recognized Duke Charles as king under the title of Charles IX.

Charles proceeded to conquer Finland, and to take cruel vengeance on the nobles who had opposed him. He did not, however, style himself king until March 6, 1604, after Duke John had formally renounced his claim to the throne, and was not crowned until March 15, 1607. His short reign was a period of uninterrupted warfare. In the long war with Poland (1600–60), begun in his reign, he was on the whole unsuccessful, his severest defeat being at Kirkholm (Sept. 1605) (see CHODKIEWICZ). Sweden and Poland also supported rival claimants to the tsardom in Russia. In 1610 Charles, who had concluded an alliance with the tsar Basil against Sigismund in 1609 and who aimed at obtaining the county of Keksholm for Sweden, sent an army under Jacob de la Gardie (*q.v.*) to Moscow. After his defeat by the Polish general, Zolkiewski, at Klutsjino (June, 1610) and the collapse of Basil, de la Gardie seized Keksholm and Novgorod in 1611. In the same year Christian IV. of Denmark (*q.v.*) declared war on Sweden, partly as a result of Charles's pretensions to Lapland, and his veto on trade with Riga and Kurland and his foundation of the city of Göteborg (Gothenburg), partly from an ambition to conquer Sweden. Christian besieged Kalmar (whence the name "Kalmar War," given to this war). In July, 1611, Charles IX. fought an indecisive battle near that city, and on the 28th the castle of Kalmar was surrendered treacherously. Old and worn out, Charles died on Oct. 30, leaving his son, Gustavus Adolphus, to carry on war with Denmark and Russia. As a ruler Charles IX. is the link between his great father Gustavus Vasa and his still greater son. He consolidated the work of Gustavus Vasa, the creation of a great Protestant state: he prepared the way for the erection of the Protestant empire of Gustavus Adolphus. By his first wife Marie, daughter of the elector palatine Louis VI., he had six children, of whom only one daughter, Catherine, survived; by his second wife, Christina, daughter of Adolphus, duke of Holstein-Gottorp, he had five children, including Gustavus Adolphus and Charles Philip, duke of Finland.

See *Sveriges Historia*, vol. iii. (1878); R. N. Bain, *Scandinavia* (1905); see also SWEDEN: *History*. (R. N. B.; X.)

CHARLES X. (CHARLES GUSTAVUS) (1622-1660), king of Sweden, son of John Casimir, count palatine of Zweibrücken, and Catherine, sister of Gustavus Adolphus, was born at Nyköping Castle on Nov. 8, 1622. He learnt the art of war under the great Lennart Torstensson, being present at the second battle of Breitenfeld and at Jankowitz. From 1646 to 1648 he frequented the Swedish court. It was supposed that he would marry the queen regnant, Christina, and to compensate her cousin for a broken half-promise she declared him (1649) her successor, despite the opposition of the senate headed by Axel Oxenstjerna. In 1648 he was appointed generalissimo of the Swedish forces in Germany, and acted as Swedish plenipotentiary at the executive congress of Nuremberg, assembled (1650) to execute the details of the peace of Westphalia. As the recognized heir to the throne, his position on his return to Sweden was a difficult one, in view of the unpopularity of the queen. Charles, therefore, wisely withdrew to the isle of Öland till the abdication of Christina (June 5, 1654) called him to the throne.

The beginning of his reign was devoted to the healing of domestic discords and in preparation for a new policy of conquest. He contracted a political marriage (Oct. 24, 1654) with Hedwig Leonora, the daughter of Frederick III., duke of Holstein-Gottorp, by way of securing a future ally against Denmark. The two great pressing national questions, war and the restitution of the alienated crown lands, were considered at the *Riksdag* which assembled at Stockholm in March 1655. The war question was decided in three days by a secret committee presided over by the king, who easily persuaded the delegates that a war with Poland was necessary and might prove very advantageous; but the consideration of the question of the subsidies due to the crown for military purposes was postponed to the following *Riksdag* (see SWEDEN: *History*). On July 15 Charles quitted Sweden to engage in his Polish adventure. By the time war was declared he had at his disposal 50,000 men and 50 warships. Hostilities had already begun with the occupation of Düna (Dvinsk) in Polish Livonia by the Swedes (July 1, 1655), and the Polish army encamped among the marshes of the Netze concluded a convention (July 25) whereby the palatinates of Posen and Kalisz placed themselves under the protection of the Swedish king. The Swedes then entered Warsaw without opposition and occupied the whole of Great Poland. The Polish king, John Casimir, fled to Silesia. Meanwhile Charles pressed on towards Cracow, which was captured after a two months' siege. The fall of Cracow extinguished the last hope of the boldest Pole; but before the end of the year an extraordinary reaction began in Poland itself. On Oct. 18 the Swedes invested the fortress-monastery of Czenstochowa, but the place was heroically defended; and after a seventy days' siege the besiegers were compelled to retire with great loss.

This astounding success elicited an outburst of popular enthusiasm which gave the war a national and religious character. The tactlessness of Charles, the rapacity of his generals, the barbarity of his mercenaries, his refusal to legalize his position by summoning the Polish diet, his negotiations for the partition of the very state he affected to befriend, awoke the long slumbering public spirit of the country. In the beginning of 1656 John Casimir returned from exile and the Polish army was reorganized and increased. By this time Charles had discovered that it was easier to defeat the Poles than to conquer Poland. His chief object, the conquest of Prussia, was still unaccomplished, and a new foe arose in the elector of Brandenburg, alarmed by the ambition of the Swedish king. Charles forced the elector, indeed, at the point of the sword to become his ally and vassal (treaty of Königsberg, Jan. 17, 1656); but the Polish national rising now imperatively demanded his presence in the south. For weeks he scoured the interminable snow-covered plains of Poland in pursuit of the Polish guerillas, penetrating as far south as Jaroslav in Galicia, by which time he had lost two-thirds of his 15,000 men with no apparent result. His retreat from Jaroslav to Warsaw, with the fragments of his host, amidst three converging armies, in a marshy forest region, intersected in every direction by well-guarded rivers, was one of his most brilliant achievements. But his necessities were overwhelming. On June 21 Warsaw was re-

taken by the Poles, and four days later Charles was obliged to purchase the assistance of Frederick William by the treaty of Marienburg. On July 18-20 the combined Swedes and Brandenburgers, 18,000 strong, after a three days' battle, defeated John Casimir's army of 50,000 at Warsaw and reoccupied the Polish capital; but this brilliant feat of arms was altogether useless, and when the suspicious attitude of Frederick William compelled the Swedish king at last to open negotiations with the Poles, they refused the terms offered, the war was resumed, and Charles concluded an offensive and defensive alliance with the elector of Brandenburg (treaty of Labiau, Nov. 20) whereby it was agreed that Frederick William and his heirs should henceforth possess the full sovereignty of East Prussia. In the meantime the hostile Dutch dominated Danzig, and the tsar started a campaign against the Swedish Baltic provinces.

The alliance of the elector had now become indispensable on almost any terms. So serious, indeed, were the difficulties of Charles X. in Poland, in spite of the assistance of the elector and of George Rákóczy II., prince of Transylvania, that it was with extreme satisfaction that he received the tidings of the Danish declaration of war (June 1, 1657) which enabled him honourably to emerge from the inglorious Polish imbroglio. He had learnt from Torstensson that Denmark was most vulnerable if attacked from the south, and, imitating the strategy of his master, he fell upon her with a velocity which paralyzed resistance. At the end of June 1657, at the head of 6,000 seasoned veterans, he executed a rapid march from the interior of Poland to Stettin, and reached the borders of Holstein on July 18. The Danish army at once dispersed and the duchy of Bremen was recovered by the Swedes, who in the early autumn swarmed over Jutland and firmly established themselves in the duchies. But the fortress of Fredriksodde (Fredericia) on the Little Belt held Charles's little army at bay from mid-August to mid-October, while the fleet of Denmark, after a stubborn two days' battle, compelled the Swedish fleet to abandon its projected attack on the Danish islands. In July an offensive and defensive alliance was concluded between Denmark and Poland. The elector of Brandenburg joined the league against Sweden, and compelled Charles to accept the proffered mediation of Cromwell and Mazarin. The negotiations foundered, however, upon the refusal of Sweden to refer to the points in dispute to a general peace-congress, and Charles was still further encouraged by the capture of Fredriksodde (Oct. 23-24). In the middle of December 1657 began the great frost which was to be so fatal to Denmark. On Jan. 28, 1658, Charles X. arrived at Haderslev (Hadersleben) in South Jutland, when it was estimated that in a couple of days the ice of the Little Belt would be firm enough to bear even the passage of a mail-clad host to the island of Fünen. Early in the morning of Jan. 30 the Swedish king gave the order to start, the horsemen dismounting where the ice was weakest, and cautiously leading their horses as far apart as possible, when they swung into their saddles again, closed their ranks and made a dash for the shore. The whole of Fünen was won with the loss of only two companies of cavalry, which disappeared under the ice while fighting with the Danish left wing. Charles, with his eyes fixed steadily on Copenhagen, resolved to cross the frozen Great Belt also. After some hesitation, he accepted the advice of his chief engineer officer Eric Dahlberg, who acted as pioneer throughout, and chose the more circuitous route from Svendborg, by the islands of Langeland, Laaland and Falster, in preference to the direct route from Nyborg to Korsör, which would have been across a broad, almost uninterrupted expanse of ice. On the night of Feb. 5 the transit began, the cavalry leading the way through the snow-covered ice, which quickly thawed beneath the horses' hoofs so that the infantry which followed after had to wade through half an ell of sludge, fearing every moment lest the rotting ice should break beneath their feet. At three o'clock in the afternoon, Dahlberg leading the way, the army reached Grimsted in Laaland without losing a man. On Feb. 8 Charles reached Falster. On the 11th he stood safely on the soil of Sjaelland (Zealand). The medal struck to commemorate "the glorious transit of the Baltic Sea" bore the haughty inscription; *Natura hoc debuit uni.*

The crushing effect of this unheard-of achievement on the Danish Government found expression in the treaties of Taastrup (Feb. 18) and Røskilde (Feb. 26, 1658), whereby Denmark sacrificed nearly half her territory to save the rest (*see DENMARK: History*). But even this was not enough for the conqueror. Military ambition and greed of conquest moved Charles X. to what, divested of all its pomp and circumstance, was an outrageous act of political brigandage. At a council held at Gottorp (July 7), Charles X. resolved, without any warning, in defiance of all international equity, to let loose his veterans upon Denmark a second time. For the details of this second struggle, with the concomitant diplomatic intervention of the western powers, who were determined to prevent the closing of the Sound, *see FREDERICK III.*, king of Denmark, and *DENMARK: History*. Only after great hesitation would Charles X. consent to reopen negotiations with Denmark direct, at the same time proposing to exercise pressure upon the enemy by a simultaneous winter campaign in Norway. Such an enterprise necessitated fresh subsidies from his already impoverished people, and obliged him in December 1659 to cross over to Sweden to meet the estates, whom he had summoned to Gothenburg. The lower estates murmured at the imposition of fresh burdens; and Charles had need of all his adroitness to persuade them that his demands were reasonable and necessary. At the very beginning of the *Riksdag*, in January 1660, it was noticed that the king was ill; but he spared himself as little in the council-chamber as in the battle-field, till death suddenly overtook him on the night of Feb. 12–13, 1660, in his thirty-eighth year.

CHARLES XI. (1655–1697), king of Sweden, the only son of Charles X. and Hedwig Leonora of Holstein-Gottorp, was born in the palace at Stockholm on Nov. 24, 1655. His father, who died when the child was in his fourth year, appointed a regency of five great ministers of state with the queen as president. For the history of the regency, of the settlement of the Danish and Russian loans, and the later humiliating dependence on France (*see SWEDEN: History*). The young king's education was neglected. When he attained his majority, he was ignorant of the very rudiments of state-craft and almost illiterate. It was the disaster of the Scanian war which first called forth his sterling qualities and hardened him into a premature manhood.

In 1675 the Brandenburgers, Pomeranians and Danes had overrun Pomerania and Bremen, and the Danes were preparing to invade Sweden itself. Amidst universal anarchy, the young king, barely twenty years of age, inexperienced, ill-served, snatching at every expedient, worked day and night in his newly-formed camp in Scania (Skåne) to arm the nation for its mortal struggle. The Danes launched invasion from three directions in 1676. The victory of Fyllebro (Aug. 17, 1676), when Charles and his commander-in-chief S. G. Helmsfeld routed a Danish division, was the first Swedish success, and on Dec. 4, on the tableland of Helgonabäck, near Lund, the young Swedish monarch defeated Christian V. of Denmark, who also commanded his army in person. After a ferocious contest, the Danes were practically annihilated. The battle of Lund was, relatively to the number engaged, one of the bloodiest engagements of modern times. More than half the combatants (8,357, of whom 3,000 were Swedes) actually perished on the battle-field. All the Swedish commanders, notably John Gyllenstierna, showed remarkable ability, but the chief glory of the day indisputably belongs to Charles XI. This great victory restored to the Swedes their self-confidence and prestige. In the following year, Charles with 9,000 men routed 12,000 Danes near Landskrona (July 15, 1678). This proved to be the last pitched battle of the war, the Danes never again venturing to attack their once more invincible enemy in the open field. In Germany, the Swedes, faced by the Great

Elector, lost ground. In 1679 Louis XIV. dictated the terms of a general pacification, and Charles XI., who bitterly resented "the insufferable tutelage" of the French king, acquiesced in a peace which at least left his empire practically intact. Both Christian V. of Denmark and Frederick William, the Great Elector, were forced to restore their conquests (*see SWEDEN: History*). Good understanding between Denmark and Sweden followed the peace of Lund, and there relations were cemented by the marriage of Charles with Ulrica Leonora, sister of Christian V. Charles devoted the rest of his life to the gigantic task of rehabilitating Sweden by means of a *reduktion*, or recovery of alienated crown lands, a process which involved the examination of every title deed in the kingdom, and resulted in the complete readjustment of the finances. But vast as it was, the *reduktion* represents only a tithe of Charles XI.'s immense activity. Finance, commerce, the national armaments by sea and land, judicial procedure, church government, education, even art and science—everything, in short—emerged recast from his shaping hand. For the strengthening in his reign of the power of the crown, which left Sweden practically an absolute monarchy (*see SWEDEN: History*). Charles XI. died on April 5, 1697, in his forty-first year. He had seven children, of whom only three survived him, a son Charles, and two daughters, Hedwig Sophia, duchess of Holstein, and Ulrica Leonora, who ultimately succeeded her brother on the Swedish throne.

After Gustavus Vasa and Gustavus Adolphus, Charles XI. was, perhaps, the greatest of all the kings of Sweden. His modest, homespun figure has indeed been unduly eclipsed by the brilliant and colossal shapes of his heroic father and his meteoric son; yet in reality Charles XI. is far worthier of admiration than either Charles X. or Charles XII. He was in an eminent degree a great master-builder. He found Sweden in ruins, and devoted his whole life to laying the solid foundations of a new order of things which, in its essential features, has endured to the present day.

See Martin Veibull, Sveriges Storhedstid (Stockholm, 1881); Frederick Ferdinand Carlson, *Sveriges Historia under Konungarne af Pfalziska Huset* (Stockholm, 1883–1885); Robert Nisbet Bain, *Scandinavia* (Cambridge, 1905); O. Sjögren, *Karl den Elfte och Svenska Folket* (Stockholm, 1897); S. Jacobsen, *Den nordiske Krigs Krønike, 1675–1679* (Copenhagen, 1897); J. A. de Mesmes d'Avaux, *Négociations du comte d'Avaux, 1693, 1697, 1698* (Utrecht, 1882, etc.).

CHARLES XII. (1682–1718), king of Sweden, the only surviving son of Charles XI. and Ulrica Leonora, daughter of Frederick III. of Denmark, was born on June 17, 1682. He was carefully educated by excellent tutors under the watchful eyes of his parents. Charles XI. personally supervised his son's physical training. He was taught to ride before he was four and at eight he was quite at home in his saddle.

As he grew older his father took him on all his rounds, reviewing troops, inspecting studs, foundries, dockyards and granaries. Thus the lad was gradually initiated into all the *minutiae* of administration. The influence of Charles XI. over his son was, indeed, far greater than is commonly supposed, and it accounts for much in Charles XII.'s character which is otherwise inexplicable, for instance his precocious reserve and taciturnity, his dislike of everything French, and his inordinate contempt for purely diplomatic methods. On the whole, his early training was admirable; but the young prince was not allowed the opportunity of gradually gaining experience under his guardians. At the *Riksdag* assembled at Stockholm in 1697, the estates, jealous of the influence of the regents, offered full sovereignty to the young monarch, the senate acquiesced, and, after some hesitation, Charles at last declared that he could not resist the urgent appeal of his subjects and would take over the government of the realm "in God's name." The subsequent coronation was marked by portentous novelties, the most significant of which was the king's omission to take the usual coronation oath, which omission was interpreted to mean that he considered himself under no obligation to his subjects. The general opinion of the young king was, however, still favourable. His conduct was evidently regulated by strict principle and not by mere caprice. His intense application to affairs is noted by the English minister, John Robinson (1650–1723).

The coalition formed against Sweden by Johann Reinhold

Patkul, which resulted in the outbreak of the Great Northern War (1699), abruptly put an end to Charles XII.'s political apprenticeship, and forced the sword into his hand. The young king resolved to attack Denmark the nearest of his three enemies—Denmark, Poland and Russia—first. The timidity of the Danish admiral Ulrik C. Gyldenlöve, and the daring of Charles, who forced his nervous and protesting admiral to attempt the passage of the eastern channel of the Sound, the dangerous *flinterend*, hitherto reputed to be unnavigable, enabled the Swedish king to effect a landing at Humleback in Sjaelland (Zealand), a few miles north of Copenhagen (Aug. 4, 1700). He now hoped to accomplish what his grandfather, fifty years before, had vainly attempted—the destruction of the Danish-Norwegian monarchy by capturing its capital. But for once prudential considerations prevailed, and the short and bloodless war was terminated by the peace of Travendal (Aug. 18), whereby Frederick IV. conceded full sovereignty to Charles's ally and kinsman the duke of Gottorp, besides paying him an indemnity of 200,000 rix-dollars and solemnly engaging to commit no hostilities against Sweden in future. From Sjaelland Charles now hastened to Livonia with 8,000 men. On Oct. 6 he had reached Pernau, with the intention of first relieving Riga, but, hearing that Narva was in great straits, he decided to turn northwards against the tsar. He set out for Narva on Nov. 13 against the advice of all his generals, who feared the effect on untried troops of a week's march through a wasted land, along boggy roads guarded by no fewer than three formidable passes which a little engineering skill could easily have made impregnable. Fortunately, the first two passes were unoccupied; and the third, Pyhäjoggi, was captured by Charles, who with 400 horsemen put 6,000 Russian cavalry to flight. On Nov. 19 the little army reached Lagena, a village about 9m. from Narva, whence it signalled its approach to the beleaguered fortress, and early on the following morning it advanced in battle array. The attack on the Russian fortified camp began at two o'clock in the afternoon, in the midst of a violent snowstorm; and by night-fall the whole position was in the hands of the Swedes: the Russian army was annihilated. The triumph was as cheap as it was crushing; it cost Charles less than 2,000 men.

After Narva, Charles XII. stood at the parting of ways. His best advisers urged him to turn all his forces against the panic-stricken Muscovites; to go into winter quarters amongst them and live at their expense; to fan into a flame the smouldering discontent caused by the reforms of Peter the Great; and so disable Russia for some time to come. But Charles was determined to punish the treachery of Augustus of Poland (*see* POLAND: *History*). It is easy from the vantage-point of two centuries to criticize Charles XII. for neglecting the Russians to pursue the Saxons; but at the beginning of the 18th century his decision was natural enough. The real question was, which of the two foes was the more dangerous, and Charles had many reasons to think the civilized and martial Saxons far more formidable than the imbecile Muscovites. Charles also rightly felt that he could never trust the treacherous Augustus to remain quiet, even if he made peace with him. To leave such a foe in his rear, while he plunged into the heart of Russia would have been hazardous indeed. From this point of view Charles's whole Polish policy, which has been blamed so long and so loudly—the policy of placing a nominee of his own on the Polish throne—takes quite another complexion: it was a policy not of overvaulting ambition, but of prudential self-defence.

First, however, Charles cleared Livonia of the invader (July 1701), subsequently occupying the duchy of Courland and converting it into a Swedish governor-generalship. In Jan. 1702 Charles established himself at Bielowice in Lithuania, and, after issuing a proclamation declaring that "the elector of Saxony" had forfeited the Polish crown, set out for Warsaw, which he reached on May 14. The cardinal-primate was then sent for and commanded to summon a diet, for the purpose of deposing Augustus. A fortnight later Charles quitted Warsaw, to seek the elector; on July 2 routed the combined Poles and Saxons at Klissow; and three weeks later, captured the fortress of Cracow by an act of almost fabulous audacity. Thus, within four months

of the opening of the campaign, the Polish capital and the coronation city were both in the possession of the Swedes. After Klissow, Augustus made every effort to put an end to the war, but Charles would not even consider his offers. By this time, too, he had conceived a passion for the perils and adventures of warfare. His character was hardening, and he deliberately adopted the most barbarous expedients for converting the Augustan Poles to his views.

The campaign of 1703 was remarkable for Charles's victory at Pultusk (April 21) and the long siege of Thorn, which occupied him eight months but cost him only 50 men. On July 2, 1704, with the assistance of a bribing fund, Charles's ambassador at Warsaw, Count Arvid Bernard Horn, succeeded in forcing through the election of Charles's candidate to the Polish throne, Stanislaus Leszczyński, who could not be crowned however till Sept. 24, 1705, by which time the Saxons had again been defeated at Punitz. From the autumn of 1705 to the spring of 1706, Charles was occupied in pursuing the Russian auxiliary army under Ogilvie through the forests of Lithuania. On Aug. 5, he recrossed the Vistula and established himself in Saxony, where his presence in the heart of Europe at the very crisis of the war of the Spanish Succession, fluttered all the western diplomats. The allies, in particular, at once suspected that Louis XIV. had bought the Swedes. Marlborough was forthwith sent from the Hague to the castle of Altranstädt near Leipzig, where Charles had fixed his headquarters, "to endeavour to penetrate the designs" of the king of Sweden. He soon convinced himself that western Europe had nothing to fear from Charles, and that no bribes were necessary to turn the Swedish arms from Germany to Russia. Five months later (Sept. 1707) Augustus was forced to sign the peace of Altranstädt, whereby he resigned the Polish throne and renounced every anti-Swedish alliance. Charles's departure from Saxony was delayed for twelve months by a quarrel with the emperor. The court of Vienna had treated the Silesian Protestants with tyrannical severity, in direct contravention of the treaty of Osnabrück, of which Sweden was one of the guarantors; and Charles demanded summary and complete restitution so dictatorially that the emperor prepared for war. But the allies interfered in Charles's favour, lest he might be tempted to aid France, and induced the emperor to satisfy all the Swedish king's demands, the maritime Powers at the same time agreeing to guarantee the provisions of the peace of Altranstädt.

Nothing now prevented Charles from turning his victorious arms against the tsar; and on Aug. 13, 1707, he evacuated Saxony at the head of the largest host he ever commanded, consisting of 24,000 horse and 20,000 foot. Delayed during the autumn months in Poland by the tardy arrival of reinforcements from Pomerania, it was not till Nov. 1707 that Charles was able to take the field. On New Year's Day 1708 he crossed the Vistula, though the ice was in a dangerous condition. On July 4, 1708 he cut in two the line of the Russian army, 6m. long, which barred his progress on the Wabis, near Holowczyn, and compelled it to retreat. The victory of Holowczyn, memorable besides as the last pitched battle won by Charles XII., opened up the way to the Dnieper. The Swedish army now began to suffer severely, bread and fodder running short. The Russians slowly retired before the invader, burning and destroying everything in his path. On Dec. 20 it was plain to Charles himself that Moscow was inaccessible. But the idea of a retreat was intolerable to him, so he determined to march southwards instead of northwards as suggested by his generals, and join his forces with those of the hetman of the Dnieperian Cossacks, Ivan Mazepa, who had 100,000 horsemen and a fresh and fruitful land at his disposal. Short of falling back upon Livonia, it was the best plan adoptable in the circumstances, but it was rendered abortive by Peter's destruction of Mazepa's capital Baturin, so that when Mazepa joined Charles at Horki, on Nov. 8, 1708, it was as a ruined man with little more than 1,300 personal attendants (*see* MAZEPA-KOLEDINSKY). A still more serious blow was the destruction of the relief army which Levenhaupt was bringing to Charles from Livonia, and which, hampered by hundreds of loaded wagons, was overtaken and almost destroyed by Peter at Lyesna after a two days'

battle against fourfold odds (October). The very elements now began to fight against the perishing but still unconquered host. The winter of 1708 was the severest that Europe had known for a century. By Nov. 1 firewood would not ignite in the open air, and the soldiers warmed themselves over big bonfires of straw. By the time the army reached the little Ukrainian fortress of Hadjacz in January 1709, wine and spirits froze into solid masses of ice; birds on the wing fell dead.

Never had Charles XII. seemed so superhuman as during these awful days. It is not too much to say that his imperturbable equanimity, his serene *bonhomie* kept the host together. The frost broke at the end of Feb. 1709, and then the spring floods put an end to all active operations till May, when Charles began the siege of the fortress of Poltava, which he wished to make a base for subsequent operations while awaiting reinforcements from Sweden and Poland. On June 7 a bullet wound put Charles *hors de combat*, whereupon Peter threw the greater part of his forces over the river Vorskla, which separated the two armies (June 19–25). On June 26 Charles held a council of war, at which it was resolved to attack the Russians in their entrenchments on the following day. The Swedes joyfully accepted the chances of battle and, advancing with irresistible *élan*, were, at first, successful on both wings. Then one or two tactical blunders were committed; and the tsar, taking courage, enveloped the little band in a vast semicircle bristling with the most modern guns, which fired five times to the Swedes' once, and swept away the guards before they could draw their swords. The Swedish infantry was well nigh annihilated, while the 14,000 cavalry, exhausted and demoralized, surrendered two days later at Perevolochna on Dnieper. Charles himself with 1,500 horsemen took refuge in Turkish territory.

For the first time in his life Charles was now obliged to have recourse to diplomacy; and his pen proved almost as formidable as his sword. He procured the dismissal of four Russophil grand-viziers in succession, and between 1710 and 1712 induced the Porte to declare war against the tsar three times. But after Nov. 1712 the Porte had no more money to spare; and, the tsar making a show of submission, the sultan began to regard Charles as a troublesome guest. On Feb. 1, 1713 he was attacked by the Turks in his camp at Bender, and made prisoner. Charles lingered on in Turkey 15 months longer, in the hope of obtaining a cavalry escort sufficiently strong to enable him to restore his credit in Poland. Disappointed of this last hope, and moved by the despairing appeals of his sister Ulrica and the senate to return to Sweden while there was still a Sweden to return to, he quitted Demotika on Sept. 20, 1714, and attended by a single squire arrived unexpectedly at midnight, on Nov. 11, at Stralsund.

For the diplomatic events of these critical years see SWEDEN: *History*. Here it need only be said that Sweden, during the course of the Great Northern War, had innumerable opportunities of obtaining an honourable and even advantageous peace, but they all foundered on the dogged refusal of Charles to consent to the smallest concession to his despoilers. Even now he would listen to no offers of compromise, and after defending Stralsund with desperate courage till it was a mere rubbish heap, returned to Sweden after an absence of 14 years. Here he collected another army of 20,000 men, with which he so strongly entrenched himself on the Scanian coast in 1716 that his combined enemies shrank from attacking him, whereupon he assumed the offensive by attacking Norway in 1717, and again in 1718, in order to conquer sufficient territory to enable him to extort better terms from his enemies. It was during this second adventure that he met his death. On Dec. 11, when the Swedish approaches had come within 280 paces of the fortress of Fredriksten, which the Swedes were closely besieging, Charles looked over the parapet of the foremost trench, and was shot through the head.

CHARLES XIII. (1748–1818), king of Sweden and Norway, the second son of Adolphus Frederick, king of Sweden, and Louisa Ulrica, sister of Frederick the Great, was born at Stockholm on Oct. 7, 1748. In 1772 he co-operated in the revolutionary plans of his brother Gustavus III. (*q.v.*). During the Russo-Swedish War of 1788 he served as admiral of the fleet at the battles of Hogland (June 17, 1788) and Öland (July 26, 1789). On the death of Gustavus III., Charles, now duke of Sudermania, acted as regent of Sweden till 1796; but the real ruler of the country was Gustaf Adolf Reuterholm (*q.v.*). These four years may be briefly described as alternations of fantastic Jacobinism and ruthless despotism. On the accession of Gustavus IV. (Nov. 1796), the duke became a mere cipher in politics till March 13, 1809, when those who had dethroned Gustavus IV. appointed him regent, and finally elected him king. But by this time he was prematurely decrepit, and Bernadotte (*see* CHARLES XIV.) took over the government as soon as he landed in Sweden (1810). By the union of 1814 Charles became the first king of Sweden and Norway. He married his cousin Hedwig Elizabeth Charlotte of Holstein-Gottorp (1759–1818), but their only child died in infancy (1798). Charles XIII., who for eight years had been king only in title, died on Feb. 5, 1818.

CHARLES XIV. (JOHN) (1763–1844), king of Sweden and Norway, born at Pau on Jan. 26, 1763, was the son of Henri Bernadotte (1711–1780), procurator at Pau, and Jeanne St. Jean (1725–1809). The family name was originally Deu Pouey, but was changed into Bernadotte in the beginning of the 17th century. Bernadotte's christian names were Jean Baptiste; he added the name Jules subsequently. He entered the French army in 1780 and first saw service in Corsica. On the outbreak of the Revolution his eminent military qualities brought him speedy promotion. In 1794 he was a brigadier attached to the army of the Sambre et Meuse, and after Jourdan's victory at Fleurus he was appointed a general of division. At the battle of Theiningen, 1796, he contributed, more than any one else, to the successful retreat of the French army over the Rhine after its defeat by the archduke Charles. In 1797 he brought reinforcements from the Rhine to Bonaparte's army in Italy, distinguishing himself greatly at the passage of the Tagliamento, and in 1798 was sent as ambassador to Vienna, but was compelled to quit his post owing to the disturbances caused by his hoisting the tricolour over the embassy. On Aug. 16, 1798, he married Désirée Clary (1777–1860), the daughter of a Marseille banker, and sister of Joseph Bonaparte's wife. From July 2 to Sept. 14, while Napoleon was in Egypt, he was war minister and in that capacity displayed great ability. About this time he held aloof from Bonaparte, but though he declined to help Napoleon in the preparations for the *coup d'état* of November 1799, he accepted a place on the new council of State in Jan. 1800, and from April 1800 till Aug. 18, 1801, commanded the army in La Vendée. On the introduction of the Empire he was made one of the eighteen marshals of France, and from June 1804 to September 1805 acted as governor of the recently-occupied Hanover. During the campaign of 1805 Bernadotte with an army corps from Hanover co-operated in the great movement which resulted in the shutting up of Mack in Ulm. He was rewarded for his services at Austerlitz (December 2, 1805) by the principality of Ponte Corvo (June 5, 1806); but during the campaign against Prussia in the same year, for not coming to the assistance of Marshal Davout in the battles of Jena and Auerstädt he was severely reproached by Napoleon, who did not wish it to be thought that he had not foreseen the engagement between

Davout and the Prussian army at Auerstädt. In 1808, as governor of the Hansa towns, he was to have directed the expedition against Sweden, via the Danish islands, but the plan came to nought because of the want of transports and the defection of the Spanish contingent. In the war against Austria Bernadotte led the Saxon contingent at the battle of Wagram, on which occasion on his own initiative he issued an order of the day, containing exaggerated and inaccurate compliments on the behaviour of his Saxon troops, which Napoleon at once disavowed.

Bernadotte, considerably piqued, thereupon returned to Paris, where the council of ministers entrusted him with the defence of the Netherlands against the English. In 1810 he was about to enter upon his new post of governor of Rome when on the sudden death of the crown prince of Sweden he was unexpectedly elected successor to the Swedish throne, partly because a large part of the Swedish army, in view of future complications with Russia, was in favour of electing a soldier, and partly because Bernadotte was very popular in Sweden owing to the kindness he had shown to the Swedish prisoners during the late war with Denmark. The matter was decided by one of the Swedish courtiers, Baron Karl Otto Mörner, who, entirely on his own initiative, offered the succession to the Swedish crown to Bernadotte. Bernadotte communicated Mörner's offer to Napoleon, who treated the whole affair as an absurdity. Bernadotte thereupon informed Mörner that he would not refuse the honour if he were duly elected. Although the Swedish Government, amazed at Mörner's effrontery, at once placed him under arrest on his return to Sweden, the candidature of Bernadotte, which now had the emperor's sanction and active support, gradually gained favour there, the last obstacle was removed when he joined the Lutheran Church, and on Aug. 21, 1810, he was elected crown prince.

On Nov. 2, Bernadotte made his solemn entry into Stockholm, and on the 5th he received the homage of the Estates and was adopted by Charles XIII. under the name of Charles John. The new crown prince was very soon the most popular and the most powerful man in Sweden. The infirmity of the old king and the dissensions in the council of State placed the Government, and especially the control of foreign affairs, entirely in his hands. The blockade on trade with England, which Napoleon enforced on Sweden in 1811, had ruinous effects on the country, and the crown prince was placed in an embarrassing position. The occupation by Marshal Davout in 1812 of Swedish Pomerania hastened the rapprochement between Russia and Sweden. The keynote of Charles's whole policy was the acquisition of Norway in order to divert the popular ambition from the conquest of Finland, a policy which led him into many tortuous ways (*see SWEDEN: History*). At the conference with the Tsar at Åbo in 1812 it was agreed that Russia should assist Charles with his Norwegian project; and in March 1813 a treaty was concluded with England by which Sweden was to send an army to take part in the campaign in north Germany, in return for subsidies for the conquest of Norway. After the defeats of Lützen and Bautzen, it was the Swedish crown prince who put fresh heart into the allies; and at the conference of Trachenberg he drew up the general plan for the campaign which began after the expiration of the truce of Pläswitz. Though undoubtedly sparing his Swedes unduly, to the just displeasure of the allies, Charles John, as commander-in-chief of the northern army, successfully defended the approaches to Berlin against Oudinot in August and against Ney in September; but after Leipzig he went his own way, determined at all hazards to cripple Denmark and secure Norway. For the events which led to the union of Norway and Sweden, *see SWEDEN: History* and *NORWAY: History*. As unional king, Charles XIV. (who succeeded to that title in 1818 on the death of Charles XIII.) was popular in both countries. Though his ultra-conservative views were detested, and as far as possible opposed (especially after 1823), his dynasty was never in serious danger, and Swedes and Norsemen alike were proud of a monarch with a European reputation. It is true that the *Riksdag* of 1840 meditated compelling him to abdicate, but the storm blew over and his jubilee was celebrated with great enthusiasm in 1843. He died at Stockholm on March 8, 1844. His reign was one of uninterrupted peace, and the great

material development of the two kingdoms during the first half of the 19th century was largely due to his energy and foresight.

CHARLES XV. (1826-1872), king of Sweden and Norway, eldest son of Oscar I., king of Sweden and Norway, and Josephine Beauharnais of Leuchtenberg, was born on May 3, 1826. On June 19, 1850, he married Louisa, daughter of Prince Frederick of the Netherlands. He became regent on Sept. 25, 1857, and king on the death of his father (July 8, 1859). His reign was remarkable for its manifold and far-reaching reforms. Sweden's existing communal law (1862), ecclesiastical law (1863) and criminal law (1864) were enacted. Charles XV. also materially assisted De Geer (*q.v.*) to carry through his memorable reform of the diet in 1865. Charles was a warm advocate of "pan-Scandinavianism" and the political solidarity of the three northern kingdoms, and his enthusiasm led him to give half promises of help to Denmark on the eve of the war of 1864. In view, however, of the unpreparedness of the Swedish army and the absence of support from any of the powers, Charles was forced to observe a strict neutrality. He died at Malmö on Sept. 18, 1872. Charles XV. enjoyed an unusual degree of popularity in both his kingdoms. He was an amateur painter and his *Dikter* show him to have been a true poet. He left one child, a daughter, Louisa Josephina Eugenia, who in 1869 married the crown prince Frederick of Denmark.

See C. Bååth-Holmberg, *Carl XV., som enskild man, konung och konstnär* (Stockholm, 1891); Yngvar Nielsen, *Det norske og svenske Kongehus fra 1818* (Christiania [Oslo], 1883).

CHARLES (KARL ALEXANDER) (1712-1780), prince of Lorraine, the youngest son of Leopold, duke of Lorraine, and grandson of Charles V., duke of Lorraine (*see* p. 289), was born at Lunéville on Dec. 12, 1712. After his elder brother Francis, the duke, had exchanged Lorraine for Tuscany and married Maria Theresa, Charles became an Austrian officer, and he served in the campaigns of 1737 and 1738 against the Turks. At the outbreak of the Silesian wars in 1740 (*see* AUSTRIAN SUCCESSION, WAR OF THE), the queen made her brother-in-law a field marshal, and in 1742 Charles encountered Frederick the Great for the first time at the battle of Chotusitz (May 17). He conducted the successful campaign of 1743 against the French and Bavarians. He married, Jan. 1744, Marianne of Austria (died in 1744), sister of Maria Theresa, who made them jointly governors-general of the Austrian Netherlands. When the war broke out afresh, Charles, at the head of the Austrian army on the Rhine, crossed that river, but on Frederick's resumption of the Silesian war he hurried to Bohemia, whence, aided by the advice of the veteran field marshal Traun, he quickly expelled the Prussians. He took the field again in 1745 in Silesia, but this time without the advice of Traun, and he was twice severely defeated by Frederick, at Hohenfriedberg and at Soor. Subsequently, as commander-in-chief in the Low Countries he received, at Roucoux, a heavy defeat at the hands of Marshal Saxe. His government of the Austrian Netherlands during the peace of 1749-56 was marked by many reforms. After the first reverses of the Seven Years' War (*q.v.*), Maria Theresa called Charles again to the supreme command in the field. The campaign of 1757 opened with Frederick's great victory of Prague, and Prince Charles was shut up with his army in that fortress. In the victory of the relieving army under Daun at Kolin Charles had no part, but he won the battle of Breslau, and great enthusiasm was displayed in Austria over the victory, which seemed to be the final blow to Frederick. But soon afterwards the king of Prussia routed the French at Rossbach, and, swiftly returning to Silesia, he inflicted on Charles the complete and crushing defeat of Leuthen (Dec. 5, 1757). A mere remnant of the Austrian army reassembled after the pursuit, and Charles was relieved of his command. For a year thereafter Prince Charles acted as a military adviser at

Vienna, he then returned to Brussels, where he continued to govern till his death on July 4, 1780, at the castle of Tervoeren.

See L. Percy, *Charles de Lorraine et la cour de Bruxelles sous le règne de Marie Thérèse* (1903).

CHARLES (1421-1461), prince of Viana, sometimes called Charles IV., king of Navarre, was the son of John, afterwards John II., king of Aragon, by his marriage with Blanche, daughter of Charles III. of Navarre. Both his grandfather Charles and his mother, who ruled over Navarre, had bequeathed this kingdom to Charles, whose right had also been recognized by the Cortes; but when Blanche died in 1441 her husband John seized the government. The ill-feeling between father and son was increased when in 1447 John took for his second wife Joanna Henríquez, a Castilian princess, who bore him a son, afterwards Ferdinand I., king of Spain. When Joanna began to interfere in the internal affairs of Navarre civil war broke out; and in 1452 Charles, although aided by John II., king of Castile, was taken prisoner. Released upon promising not to take the kingly title until after his father's death, the prince, again unsuccessful in an appeal to arms, took refuge in Italy with Alphonso V., king of Aragon, Naples and Sicily. In 1458 Alphonso died and John became king of Aragon, while Charles was offered Naples and Sicily. He declined these proposals, and having been reconciled with his father returned to Navarre in 1459. Aspiring to marry a Castilian princess, he was thrown into prison by his father; the Catalans rose in his favour, and John was obliged to yield. Charles was recognized as perpetual governor of Catalonia and heir to the kingdom, but he died on Sept. 23, 1461. Charles was a cultured prince; he translated the *Ethics* of Aristotle into Spanish (Saragossa, 1509) and wrote a chronicle of the kings of Navarre, *Crónica de los reyes de Navarra*, an edition of which, edited by J. Yangués y Miranda, was published at Pampeluna (1843).

See G. Desdevises du Désert, *Carlos d'Aragon* (Paris, 1889).

CHARLES [KARL LUDWIG] (1771-1847), archduke of Austria and duke of Teschen, third son of the emperor Leopold II., was born at Florence (his father being then grand-duke of Tuscany) on Sept. 5, 1771. His youth was spent in Tuscany, at Vienna and in the Austrian Netherlands, where he began his career of military service in the war of the French Revolution. He commanded a brigade at Jemappes, and in the campaign of 1793 distinguished himself at the action of Aldenhoven and the battle of Neerwinden. In this year he became *Statthalter* in Belgium and received the army rank of lieutenant field marshal, which promotion was soon followed by that to *Feldzeugmeister* (master of ordnance). In the remainder of the war in the Low Countries he held high commands, and he was present at Fleurus. In 1795 he served on the Rhine, and in the following year was entrusted with the chief control of all the Austrian forces on that river. His conduct of the operations against Jourdan and Moreau in 1796 marked him out at once as one of the greatest generals in Europe. At first falling back carefully and avoiding a decision, he finally marched away, leaving a mere screen in front of Moreau; falling upon Jourdan he beat him in the battles of Amberg and Würzburg, and drove him over the Rhine with great loss. He then turned upon Moreau's army, which he defeated and forced out of Germany. For this campaign, one of the most brilliant in modern history, see FRENCH REVOLUTIONARY WARS. In 1797 he was sent to arrest the victorious march of Gen. Bonaparte in Italy, and he conducted the retreat of the over-matched Austrians with the highest skill. In the campaign of 1799 he was once more opposed to Jourdan, whom he defeated in the battles of Osterach and Stokach, following up his success by invading Switzerland and defeating Masséna in the (first) battle of Zürich, after which he re-entered Germany and drove the French once more over the Rhine. Ill-health, however, forced him to retire to Bohemia, whence he was soon recalled to undertake the task of checking Moreau's advance on Vienna. The result of the battle of Hohenlinden had, however, foredoomed the attempt, and the archduke had to make the armistice of Steyer. His popularity was now such that the diet of Ratisbon, which met in 1802, resolved to erect a statue in his honour and to give him the title of saviour of his country; but Charles refused both distinctions.

In the short and disastrous war of 1805 the archduke Charles commanded what was intended to be the main army, in Italy, but events made Germany the decisive theatre of operations, and the defeats sustained on the Danube neutralized the success obtained by the archduke over Masséna in the desperately fought battle of Caldiero. With the conclusion of peace began his active work of army reorganization, which was first tested on the field in 1809. As generalissimo of the army he had been made field marshal some years before. As president of the Council of War, and supported by the prestige of being the only general who had proved capable of defeating the French, he promptly initiated a far-reaching scheme of reform, which replaced the obsolete methods of the 18th century, the chief characteristics of the new order being the adoption of the "nation in arms" principle and of the French war organization and tactics. The new army was surprised in the process of transition by the war of 1809, of which Charles was commander in chief; yet even so it proved a far more formidable opponent than the old, and, against the now heterogeneous army which Napoleon controlled (see NAPOLEONIC CAMPAIGNS) it succumbed only after a desperate struggle. Its initial successes were neutralized by the reverses of Abensberg, Landshut and Eckmühl; but, after the evacuation of Vienna, the archduke won the great battle of Aspern-Essling (*q.v.*) and soon afterwards fought the still more desperate battle of Wagram (*q.v.*), at the close of which the Austrians were defeated but not routed; they had inflicted upon Napoleon a loss of over 50,000 men in the two battles. At the end of the campaign the archduke gave up all his military offices, and spent the rest of his life in retirement, except a short time in 1815, when he was governor of Mainz. In 1822 he succeeded to the duchy of Saxe-Teschen. The archduke Charles married, in 1815, Princess Henrietta of Nassau-Weilburg (d. 1829). He had four sons, the eldest of whom, the archduke Albert (*q.v.*) became one of the most celebrated generals in Europe, and two daughters, the elder of whom became queen of Naples. He died at Vienna on April 30, 1847.

The caution which the archduke preached so earnestly in his strategical works, he displayed in practice only when the situation seemed to demand it, though his education certainly prejudiced him in favour of the defensive at all costs. He was at the same time capable of forming and executing the most daring offensive strategy, and his tactical skill in the handling of troops, whether in wide turning movements, as at Würzburg and Zürich, or in masses, as at Aspern and Wagram, was certainly equal to that of any leader of his time, Napoleon only excepted. The campaign of 1796 is considered almost faultless. That he sustained defeat in 1809 was due in part to the great numerical superiority of the French and their allies, and in part to the condition of his newly reorganized troops. His six weeks' inaction after the victory of Aspern is, however, open to unfavourable criticism. As a military writer, his position in the evolution of the art of war is very important, and his doctrines had naturally the greatest weight. Nevertheless they cannot but be considered as antiquated even in 1806. Caution and the importance of "strategic points" are the chief features of his system. The rigidity of his geographical strategy may be gathered from the direction that "this principle is *never* to be departed from." Again and again he repeats the advice that nothing should be hazarded unless one's army is *completely* secure, a rule which he himself neglected with such brilliant results in 1796. In his tactical writings the same spirit is conspicuous. His reserve in battle is designed to "cover a retreat." The baneful influence of these principles was shown in the maintenance of Königgrätz-Josefstadt in 1866 as a "strategic point," which was preferred to the defeat of the separated Prussian armies; in the strange plans produced in Vienna for the campaign of 1859, and in the "almost unintelligible" battle of Montebello in the same year. The theory and the practice of the archduke Charles form one of the most curious contrasts in military history. In the one he is often unreal, in the other he displayed, besides great skill, a vivid activity which made him for long the most formidable opponent of Napoleon.

His writings were edited by the archduke Albert and his brother

the archduke William in the *Ausgewählte Schriften seiner Kgl. Hoheit Erz. Karl v. Österreich* (1862; reprinted 1893, Vienna and Leipzig), which includes the *Grundsätze der Kriegskunst für die Generale* (1806), *Grundsätze der Strategie erläutert durch die Darstellung des Feldzugs 1796* (1814), *Gesch. des Feldzugs von 1799* (1819)—the two latter invaluable contributions to the history of the war, and papers "on the higher art of war," etc. See, besides the histories of the period, F. J. A. Schneidawind, *Karl, Erzherzog v. Österr. und die österr. Armee* (Vienna, 1840) and *Das Buch vom Erz. Karl* (1848); Ed. Duller, *Erzh. Karl von Österr.* (1845-47); H. von Zeissberg, *Erzh. Karl von Österr.* (Vienna, 1893); C. von Binder-Kriegelstein, *Geist und Stoff im Kriege* (Vienna, 1893); M. (1905).

CHARLES (c. 1319-1364), duke of Brittany, known as CHARLES OF BLOIS and CHARLES OF CHÂTILLON, was the son of Guy of Châtillon, count of Blois (d. 1342), and of Marguerite of Valois, sister of Philip VI. of France. In 1337 he married Jeanne of Penthièvre (d. 1384), daughter of Guy of Brittany, count of Penthièvre (d. 1331), and thus acquired a right to the succession of the duchy of Brittany. On the death of John III. duke of Brittany, in April 1341, his brother John, count of Montfort-l'Amaury, and his niece Jeanne, wife of Charles of Blois, disputed the succession. Charles of Blois, sustained by Philip VI., captured John of Montfort, who was supported by King Edward III. at Nantes, besieged his wife Jeanne of Flanders at Hennebont, and took Quimper and Guérande (1344). But next year his partisans were defeated at Cadoret, and in June 1347 he was himself wounded and taken prisoner at Roche-Derrien. He was not liberated until 1356, when he continued the war against the young John of Montfort, and perished in the battle of Auray, on Sept. 29, 1364.

See Simeon Luce, *Histoire de Bertrand du Guesclin et de son époque* (1876); also *Monuments du procès de canonization du bienheureux Charles de Blois, duc de Bretagne, 1320-64* (Saint-Brieux, 1921).

CHARLES, called THE BOLD (1433-1477), duke of Burgundy, son of Philip the Good of Burgundy and Isabella of Portugal, was born at Dijon on Nov. 10, 1433. In his father's lifetime he bore the title of count of Charolais. He was brought up under the direction of the seigneur d'Auxy. Although he was on familiar terms with the dauphin (afterwards Louis XI.), when the latter was a refugee at the court of Burgundy, he was annoyed by the repurchase by the king of France of the towns on the Somme, which had been temporarily ceded to Philip the Good by the treaty of Arras; and when he took over the government (which his father abandoned to him completely by an act of April 12, 1465), he entered upon his lifelong struggle against Louis XI., and became one of the principal leaders of the League of the Public Weal. His brilliant bravery at the battle of Monthéry (July 16, 1465), did not assure a diplomatic victory. He succeeded, however, in forcing upon Louis the treaty of Conflans (1466), by which the king restored to him the towns on the Somme, and promised him the hand of his infant daughter Catherine, with Champagne as dowry. In the meanwhile the count of Charolais obtained the surrender of Ponthieu. The revolt of Liège and Dinant intervened to divert his attention from the affairs of France. On Aug. 25, 1466 Charles took Dinant, which he pillaged and sacked, and then treated with the Liégeois. After the death of Philip the Good (June 15, 1467), the Liégeois renewed hostilities, but Charles defeated them at St. Trond, and made a victorious entry into Liège.

Louis then requested a meeting with Charles and placed himself in his hands at Péronne. In the course of the negotiations the duke was informed of a fresh revolt of the Liégeois secretly fomented by Louis, but Charles decided to respect the parole he had given and to treat with Louis (Oct. 1468), at the same time forcing him to assist in quelling the revolt. The town was carried by assault, and the inhabitants were massacred, Louis not having the courage to intervene on behalf of his ancient allies. At the expiry of the one year's truce which followed the treaty of Péronne, the king accused Charles of treason, cited him to appear before the parlement, and seized some of the towns on the Somme (1471). The duke retaliated by invading France with a large army, taking possession of Nesle and massacring its inhabitants. He failed in an attack on Beauvais, but ravaged the country as far as Rouen.

Since the beginning of his reign Charles had employed himself in reorganizing his army and the administration of his territories. He lost no opportunity to extend his power. In 1469 the archduke of Austria, Sigismund, had sold him the county of Ferrette, and the landgraviate of Alsace and some other towns, reserving to himself the right to repurchase. In 1472-1473 Charles bought the reversion of the duchy of Gelderland from its old duke, Arnold. He conceived the project of forming a kingdom of Burgundy or Arles with himself as independent sovereign, and even persuaded the emperor Frederick to assent to crown him king at Trier. The ceremony, however, did not take place owing to the emperor's precipitate flight by night (Sept. 1473), occasioned by his displeasure at the duke's attitude. In the following year Charles involved himself in a series of quarrels which ultimately brought about his downfall. He embroiled himself successively with Sigismund of Austria, to whom he refused to restore his possessions in Alsace for the stipulated sum; with the Swiss, who supported the free towns of Alsace in their revolt against the tyranny of the ducal governor, Peter von Hagenbach (who was condemned and executed by the rebels in May 1474); and finally, with René of Lorraine, with whom he disputed the succession of Lorraine, the possession of which had united the two principal portions of Charles's territories—Flanders and the duchy and county of Burgundy. All these enemies, incited and supported as they were by Louis, were not long in joining forces against their common adversary. Charles suffered a first rebuff in endeavouring to protect his kinsman, the archbishop of Cologne, against his rebel subjects. He spent ten months (July 1474-June 1475) in besieging the little town of Neuss on the Rhine, but was compelled by the approach of a powerful imperial army to raise the siege. Moreover, the expedition he had persuaded his brother-in-law, Edward IV. of England, to undertake against Louis was stopped by the treaty of Picquigny (Aug. 29, 1475). He was more successful in Lorraine, where he seized Nancy (Nov. 30, 1475). From Nancy he marched against the Swiss, hanging and drowning the garrison of Granson in spite of the capitulation. Some days later, however, he was attacked before Granson by the confederate army and was compelled to fly with a handful of attendants, leaving his artillery and an immense booty in the hands of the allies (Feb. 1476). He succeeded in raising a fresh army of 30,000 men, with which he attacked Morat, but he was again defeated by the Swiss army, assisted by the cavalry of René of Lorraine (June 22, 1476). On Oct. 6th Charles lost Nancy, which was re-entered by René. Making a last effort, Charles formed a new army and arrived in the depth of winter before the walls of Nancy. Having lost many of his troops through the severe cold, it was with only a few thousand men that he met the joint forces of the Lorrainers and the Swiss, who had come to the relief of the town (Jan. 6, 1477). He himself perished in the fight, his mutilated body being discovered some days afterwards.

Charles the Bold has often been regarded as the last representative of the feudal spirit, and accordingly has often been contrasted with his rival Louis XI. as representing modern politics. In reality, he was a prince of wide knowledge and culture and austere morals; and although he cannot be acquitted of occasional harshness, he had the secret of winning the hearts of his subjects, who never refused him their support in times of difficulty. He was thrice married—to Catherine (d. 1446), daughter of Charles VII. of France; to Isabella (d. 1465), daughter of Charles I., duke of Bourbon, by whom he had one daughter, Mary, afterwards the wife of the Emperor Maximilian I.; and to Margaret of York, sister of Edward IV. of England, whom he married in 1468.

See *Mémoires* of Philippe de Comines, and of Olivier de la Marche. See also A. Molinier, *Les Sources de l'histoire de France*, tome iv. (1904), and the compendious bibliography in U. Chevalier's *Répertoire des sources historiques*, part iii. (1904); J. F. Kirk, *Charles the Bold* (1863-68); L. M. J. Chaumont, *Charles-le-Hardi* (1904); and R. Putnam, *Charles the Bold* (1908).

CHARLES I. (c. 950-c. 992), duke of Lower Lorraine, was a younger son of the Frankish king Louis IV., and consequently a member of the Carolingian family. In 977 he received from the emperor Otto II. the duchy of Lower Lorraine, where his authority was nominal; but he aided Otto in his struggle with

Lothair, and on the death of his nephew, Louis V., made an effort to secure the Frankish crown. Hugh Capet, however, was the successful candidate and war broke out. Charles had gained some successes and had captured Reims, when in 991 he was treacherously seized by Adalberon, bishop of Laon, and handed over to Hugh. Imprisoned with his wife and children at Orleans, Charles did not long survive his humiliation. His eldest son Otto, duke of Lower Lorraine, died in 1005.

See F. Lot, *Les derniers Carolingiens, Lothaire, Louis V., Charles de Lorraine 954-991* (1891).

CHARLES II. (d. 1431), duke of Lorraine, called **THE BOLD**, is sometimes referred to as Charles I. A son of Duke John I., he succeeded his father in 1390; but he neglected his duchy and passed his life in warfare. He died on Jan. 25, 1431, leaving two daughters, one of whom, Isabella (d. 1453) married René I. of Anjou (1409-80), king of Naples, who succeeded his father-in-law as duke of Lorraine.

CHARLES III. or II. (1543-1608), called **THE GREAT**, duke of Lorraine, was a son of Duke Francis I. (d. 1545), and a descendant of René of Anjou. Born at Nancy on Feb. 18, 1543, he was brought up at the court of Henry II. of France, marrying Henry's daughter Claude in 1559. He took part in the wars of religion in France, and was a member of the League. The duke, who was an excellent ruler of Lorraine, died at Nancy on May 14, 1608. He had three sons: Henry (d. 1624) and Francis (d. 1632), who became in turn dukes of Lorraine, and Charles (d. 1607), bishop of Metz and Strasbourg.

CHARLES IV. or III. (1604-1675), duke of Lorraine, son of Duke Francis II., was born at Nancy on April 5, 1604. He became duke on the abdication of his father, and obtained the duchy of Bar through his marriage with his cousin Nicole, daughter of Duke Henry II. Mixing in the tortuous politics of his time, he was perpetually intriguing against the crown of France. In 1627 he began negotiations with England against Louis XIII., at the same time giving assistance to Austria against the Swedes. In 1632 Louis XIII. entered his duchy and compelled him to sign the treaty of Liverdun (June 26th) and in the following year a fresh intrigue was punished by the cession of Nancy to France for four years. On Jan. 19, 1634, the duke abdicated in favour of his brother, the cardinal, Francis of Lorraine, and entered the imperial service. He was banished from the kingdom, and the duchy of Bar was confiscated. Charles took part in the battle of Nordlingen in 1634, and fought in Lorraine, Alsace and Artois; on March 29, 1641, by the treaty of Saint-Germain his duchies were restored to him in return for the cession of certain towns to France, but they were seized again, and declared neutral in June, 1644. After this Charles served with the imperialists, and later with Spain. In 1652 he joined Condé in the war of the Fronde, but was arrested by the Spaniards, with whom he had broken faith, and imprisoned at Antwerp and at Toledo. At the peace of the Pyrenees he was restored to liberty and to his duchies, but by the treaty of Montmartre (Feb. 6, 1662), he sold them to Louis XIV. This arrangement was annulled by the treaty of Nomény, in August 1663. In Sept. 1670 Charles was again expelled from his duchy by Marshal Créquy, and in 1673 he joined the second coalition against France. Turenne inflicted a severe defeat on him at Sinzheim in 1674, but on August 11, 1675, Charles was victorious at Konzerbrücke. He died some weeks later at Larbach on Sept. 18, 1675, leaving by his second wife, Béatrix de Cusance, a son, Charles Henry, count of Vaudemont (1642-1723).

See Des Roberts, *Campagnes de Charles IV. duc de Lorraine et de Bar, 1638-48* (2 vols., 1883-88), and *Charles IV. et Mazarin* (1899).

CHARLES V. or IV. (1643-1690), duke of Lorraine, nephew of Duke Charles IV., was born on April 3, 1643. He was constantly on active service in the imperial army against the Turks, and later against the French. He was twice (1668 and 1674) an unsuccessful candidate for the elective crown of Poland, being defeated the second time by John Sobieski; in 1678 he married the widowed queen of Poland, Eleonora Maria of Austria. In 1675, on the death of Duke Charles IV., he rode with a cavalry corps into the duchy of Lorraine, then occupied by the French,

and secured the adhesion of the Lorraine troops. Soon after this he was made general of the imperial army on the Rhine, and distinguished himself by the capture of Philippsburg in 1676. At the general peace Charles had to accept the hard conditions imposed by Louis XIV., and he never entered into effective possession of his sovereignty. In 1683, at the head of a weak imperial army, he offered resistance to the advance of the Turks on Vienna. At the critical moment, when the Turks finally invested Vienna on July 13, 1683, reinforcements from other powers poured into Charles's camp, and with the aid of John Sobieski and his 27,000 Poles, Charles routed the Turks on Sept. 12, and relieved Vienna. The victors then took the offensive and reconquered part of Hungary; the Germans and Poles went home in the winter, but Charles continued his offensive with the imperial army alone. In 1685 Neuhausel was taken by storm, and in 1686 he resumed the siege of Ofen (Buda), which he had failed to take in 1684. On Sept. 2, 1686, Ofen was stormed, and in the following campaign the Austrians won a decisive victory on the famous field of Mohacs (Aug. 18, 1687). In 1689 Charles took the field on the Rhine against Louis XIV. Mainz and Bonn were taken in the first campaign, but Charles died suddenly, on his way to the front, at Wels on April 18, 1690. His eldest son, Leopold Joseph (1679-1729), obtained the duchy at the peace of Ryswick in 1697.

CHARLES II. (CHARLES LOUIS DE BOURBON) (1799-1883), duke of Parma, succeeded his mother, Maria Louisa in the duchy of Lucca in 1824. He introduced economy into the administration, increased the schools, and in 1832 became a Protestant. In 1842 he returned to the Catholic Church and made Thomas Ward, an English groom, his prime minister, a man not without ability and tact. In 1847 he declared himself hostile to the reforms introduced by Pius IX. The Lucchesi demanded the constitution of 1805, promised them by the Treaty of Vienna, and a national guard, but the duke, in spite of the warnings of Ward, refused all concessions. A few weeks later he sold his life-interest in the duchy to Tuscany. On Oct. 17 Maria Louisa of Austria, duchess of Parma, died, and Charles Louis succeeded to her throne by the terms of the Florence treaty, assuming the style of Charles II. His administration of Parma was characterized by ruinous finance, debts, disorder and increased taxation, and he concluded an offensive and defensive alliance with Austria. After the outbreak of the revolution in 1848, he abdicated in April and left Parma in the hands of a provisional Government, whereupon the people voted for union with Piedmont. Later Charles II. issued an edict from Weistropp annulling the acts of the provisional Government.

In May 1849 Charles confirmed his abdication, and was succeeded by his son **CHARLES III.** (1823-1854), who, protected by Austrian troops, placed Parma under martial law, inflicted heavy penalties on the members of the late provisional Government, closed the university and instituted a regular policy of persecution. A violent ruler, a drunkard and a libertine, he was assassinated on March 26, 1854. At his death his widow Maria Louisa, sister of the comte de Chambord, became regent during the minority of his son Robert. The duchess introduced some sort of order into the administration, seemed inclined to rule more mildly and dismissed some of her husband's more obnoxious ministers, but the riots of the Mazzinians in July 1854 were repressed with ruthless severity, and the rest of her reign was characterized by political trials, executions and imprisonments, to which the revolutionists replied with assassinations.

CHARLES (1270-1325), count of Valois, of Maine, and of Anjou, third son of Philip III., king of France, was born on March 12, 1270. He inherited the four lordships of Crépy, La Ferté-Milon, Pierrefonds and Béthisy, which together formed the countship of Valois. In 1284 Martin IV., having excommunicated Pedro III., king of Aragon, offered that kingdom to Charles. King

Philip failed in an attempt to place his son on this throne, and died on the return of the expedition. In 1290 Charles married Margaret, daughter of Charles II., king of Naples, and renounced his pretensions to Aragon. In 1294, at the beginning of the hostilities against England, he invaded Guienne and took La Réole and Saint-Sever. During the war with Flanders (1300), he took Douai, Béthune and Dam, received the submission of Guy of Dampierre, and aided King Philip IV., the Fair, to gain the battle of Mons-en-Pévèle, on Aug. 18, 1304. Asked by Boniface VIII. for his aid against the Ghibellines, he crossed the Alps in June 1301, entered Florence, and helped Charles II., the Lame, king of Sicily, to reconquer Calabria and Apulia from the house of Aragon, but was defeated in Sicily. As after the death of his first wife Charles had married Catherine de Courtenay, a granddaughter of Baldwin II., the last Latin emperor of Constantinople, he tried to assert his rights to that throne. Philip the Fair also wished to get him elected emperor; but Clement V. quashed his candidature in favour of Henry of Luxemburg, afterwards the emperor Henry VII. Under Louis X. Charles headed the party of feudal reaction, and was among those who compassed the ruin of Enguerrand de Marigny. In the reign of Charles IV., the Fair, he fought yet again in Guienne (1324), and died at Perray (Seine-et-Oise) on Dec. 16, 1325. His second wife died in 1307, and in July 1308 he married a third wife, Mahaut de Châtillon, countess of Saint-Pol. Philip, his eldest son, ascended the French throne in 1328, and from him sprang the royal house of Valois. See J. Petit, *Charles de Valois* (1900).

CHARLES, ELIZABETH (1828-1896), English author, was born at Tavistock on Jan. 2 1828, the daughter of John Rundle, M.P., and died at Hampstead on March 28 1896. In 1851 she married Andrew Paton Charles. Her best known book, *The Chronicles of the Schönberg-Cotta Family*, was published in 1862, and was translated into most of the European languages, into Arabic, and into many Indian dialects. Mrs. Charles wrote in all some 50 books, the majority of a semi-religious character.

CHARLES, JACQUES ALEXANDRE CÉSAR (1746-1823), French mathematician and physicist, was born at Beaugency, Loiret, on Nov. 12, 1746. From being a clerk in the ministry of finance, he turned to scientific pursuits, and became one of the most acute of physical researchers and inventors. He was the first, in 1783, to employ hydrogen for the inflation of balloons (see *AERONAUTICS*), and about 1787 he anticipated Gay Lussac's law of the dilatation of gases with heat, which on that account is sometimes known by his name. He improved the Gravesand heliostat and the aerometer of Fahrenheit and invented a "thermometric hydrometer," a "goniometer by reflection" and many other ingenious physical devices. In 1785 he was elected to the Academy of Sciences, and subsequently he became professor of physics at the Conservatoire des Arts et Métiers. He died in Paris on April 7, 1823. His published papers are chiefly concerned with mathematical topics.

CHARLES, THOMAS (1755-1814), Welsh Nonconformist divine, was born at Longmoor, Carmarthenshire, on Oct. 14, 1755, and educated at Jesus college, Oxford, for the Church. He was ordained priest in 1782, and held some curacies in Somersetshire, but he resigned these in 1783 and returned to Wales. He had fallen under the influence of the Welsh revivalists before he went to Oxford, and had Methodist connections. He found no pulpit open to him in the Church in Wales, and joined the Calvinistic Methodists in 1784.

He had already begun to provide classes for poor children in Bala; he now held the classes in the chapel, and gradually began the system of Welsh Circulating Schools, on the model devised by Griffith Jones (d. 1761). By 1794 he had 20 travelling masters at work. In 1785 he had become the agent of the Sunday School Society in Wales; he secured supplies of Welsh Bibles from the S.P.C.K. and in 1801 alone nearly 3,000 were distributed. In 1802 he went to London to place Welsh requirements before the Religious Tract Society, and put his case so well that his friends decided to found a society for the publication and distribution of the Scriptures. This was the origin of the British and Foreign Bible Society. He stimulated similar educational movements in

Ireland and Scotland. In 1810 he led the movement for the establishing of a regular ordained ministry in the Calvinistic Methodist connection, and, this work accomplished, returned to his task of fostering auxiliary Bible societies. He died on Oct. 5, 1814. Charles compiled the *Geiriadur Ysgrhythrol*, a biblical dictionary (4 vols. 1805-08), which has passed through many editions; he drew up the first definite constitution of the Welsh Methodists, and wrote many Welsh tracts. The first Welsh biography of Charles appeared in 1816. See W. Hughes, *Life and Letters of Thomas Charles* (Rhyl 1881), in which some of Charles's minor writings are reprinted.

CHARLES ALBERT (CARLO ALBERTO) (1798-1849), king of Sardinia (Piedmont), son of Prince Charles of Savoy-Carignano and Princess Albertine of Saxe-Courland, was born on Oct. 12, 1798, a few days before the French occupied Piedmont and forced his cousin, King Charles Emmanuel, to take refuge in Sardinia. In 1802 King Charles Emmanuel abdicated in favour of his brother, Victor Emmanuel I. On the fall of Napoleon in 1814 the Piedmontese court returned to Turin, and the king was anxious to secure the succession for Charles Albert, knowing that Austria meditated excluding him from it in favour of an Austrian archduke. He was summoned to Turin, given tutors to instruct him in legitimist principles, and on Oct. 1, 1817, married the archduchess Maria Theresa of Tuscany, who, on March 14, 1820, gave birth to Victor Emmanuel, afterwards king of Italy.

The Piedmontese government at this time was most reactionary, and had made a clean sweep of all French institutions. But there were strong Italian nationalists and anti-Austrian tendencies among the younger nobles and army officers, and the Carbonari and other revolutionary societies had made much progress. Their hopes centred in the young Carignano, whose agreeable manners had endeared him to all, and who had many friends among the Liberals and Carbonari. Early in 1820 a revolutionary movement was set on foot. Charles Albert no doubt was aware of this, but he never actually became a Carbonaro, and was surprised and startled when after the outbreak of the Neapolitan revolution of 1820 some of the leading conspirators in the Piedmontese army informed him that a military rising was ready and that they counted on his help (March 2, 1821). He induced them to delay the outbreak and informed the king, requesting him, however, not to punish anyone. On the 10th the garrison of Alessandria mutinied, and two days later Turin was in the hands of the insurgents, the people demanding the Spanish constitution. The king at once abdicated and appointed Charles Albert regent. The latter, pressed by the revolutionists and abandoned by his ministers, granted the constitution and sent to inform Charles Felix, who was now king, of the occurrence. Charles Felix, who was then at Modena, repudiated the regent's acts, accepted Austrian military assistance, with which the rising was easily quelled, and exiled Charles Albert to Florence. The young prince found himself the most unpopular man in Italy, for while the Liberals looked on him as a traitor, to the king and the Conservatives he was a dangerous revolutionist. At the Congress of Verona (1822) the Austrian chancellor, Prince Metternich, tried to induce Charles Felix to set aside Charles Albert's rights of succession. But the king was piqued by Austria's interference, and as both the grand-duke of Tuscany and the duke of Wellington supported him, Charles Albert's claims were respected. But it was not until he had signed a secret undertaking binding himself, as soon as he ascended the throne, to place himself under the tutelage of a council composed of the higher clergy, and the knights of the Annunziata, and to maintain the existing forms of the monarchy (D. Berti, *Cesare Alfieri*, xi. 77, Rome, 1871), that he was allowed to return to Turin and forgiven.

On the death of Charles Felix (April 27, 1831) Charles Albert succeeded; he inherited a kingdom without an army, with an empty treasury, a chaotic administration and mediaeval laws. His first task was to set his house in order; he reorganized the finances, created the army, and started Piedmont on a path which, if not liberalism, was at least progress. In 1833 a conspiracy of the *Giovane Italia* society, organized by Mazzini, was discovered, and a number of its members punished with ruthless severity. The election in 1846 of Pius IX., who appeared to be a Liberal and an

Italian patriot to some extent, reconciled the king to the Liberal movement, for it accorded with his religious views. On Oct. 30 he issued a decree granting wide reforms, and when risings broke out in other parts of Italy early in 1848, and further liberties were demanded, he was at last induced to grant the constitution (Feb. 8).

When the news of the Milanese revolt against the Austrians reached Turin (March 19) public opinion demanded that the Piedmontese should succour their struggling brothers; and after some hesitation the king declared war. But much time had been wasted and many precious opportunities lost. With an army of 60,000 Piedmontese troops and 30,000 men from other parts of Italy the king took the field, and after defeating the Austrians at Pastrengo on April 30, and at Goito on May 30, where he was himself slightly wounded, more time was wasted in useless operations. Radetzky, the Austrian general, having received reinforcements, drove the centre of the extended Italian line back across the Mincio (July 23), and in the two days' fighting at Custozza (July 24-25) the Piedmontese were beaten, forced to retreat and to ask for an armistice. The revolutionary movement throughout Italy was breaking down, but Charles Albert felt that while he possessed an army he could not abandon the Lombards and Venetians, and determined to stake all on a last chance. On March 12, 1849, he denounced the armistice and took the field again with an army of 80,000 men. He gave the chief command to the Polish general Chrzanowski, but he was completely out-generalled and defeated at La Bicozza near Novara on the 23rd. The Piedmontese fought with great bravery, and the unhappy king sought death in vain. After the battle he asked terms of Radetzky, who demanded the occupation by Austria of a large part of Piedmont, and the heir to the throne as a hostage. Thereupon, feeling himself to be the obstacle to better conditions, Charles Albert abdicated in favour of his son Victor Emmanuel. That same night he departed alone and made his way to Oporto, where he retired into a monastery and died on July 28, 1849.

Charles Albert was not a man of first-rate ability; he was of a hopelessly vacillating character. Devout and mystical to an almost morbid degree, hating revolution and distrusting Liberalism, he was a confirmed pessimist, yet he had many noble qualities: he was brave to the verge of foolhardiness, devoted to his country, and ready to risk his crown to free Italy from the foreigner. To him the people of Italy owe a great debt, for if he failed in his object he at least materialized the idea of the Risorgimento in a practical shape, and the charges which the Republicans and demagogues brought against him were monstrously unjust.

BIBLIOGRAPHY.—Besides the general works on modern Italy, see the Marquis Costa de Beauregard's interesting volumes *La Jeunesse du roi Charles Albert* (1899) and *Novare et Oporto* (1890), based on the king's letters and the journal of Sylvain Costa, his faithful equerry, though the author's views are those of an old-fashioned Savoyard who dislikes the idea of Italian unity; Ernesto Masi's *Il Segreto del Re Carlo Alberto* (Bologna, 1891) is a very illuminating essay; Domenico Perrero, *Gli Ultimi Reali di Savoia* (Turin, 1889); L. Cappelletti, *Storia di Carlo Alberto* (1891); Nicomede Bianchi, *Storia della diplomazia europea in Italia* (8 vols., Turin, 1865, etc.), a most important work of a general character, and the same author's *Scritti e lettere di Carlo Alberto* (1879) and his *Storia della monarchia piemontese* (Turin, 1877); Count S. della Margherita, *Memorandum storico-politico* (Turin, 1851); A. Luzio, *Carlo Alberto e Giuseppe Mazzini* (1923); he also edited *Le Lettere di Carlo Alberto al Car. Luigi Bianco di Barbiana* (Turin, 1924); A. di Saluzzo, *Carlo Alberto della restaurazione all'avvenimento al trono* (1926).

CHARLES AUGUSTUS (KARL AUGUST) (1757-1828), grand-duke of Saxe-Weimar, friend and patron of Goethe, was the son of Constantine, duke of Saxe-Weimar-Eisenach, and Anna Amalia of Brunswick. Educated under the regency of his mother—his father died in 1757—Charles Augustus assumed the reins of government in 1775, in which year he married Princess Louise of Hesse-Darmstadt. In the affairs of Germany and of Europe his character gave him an influence out of all proportion to his position as a sovereign prince. He had early faced the problem presented by the decay of the empire, and began to work for the unity of Germany. The plans of the emperor Joseph II., which

threatened to absorb a great part of Germany into the heterogeneous Habsburg monarchy, threw him into the arms of Prussia, and he was the prime mover in the establishment of the league of princes (*Fürstenbund*) in 1785, by which, under the leadership of Frederick the Great, Joseph's intrigues were frustrated. He was, however, under no illusion as to the power of Austria, and he wisely refused the offer of the Hungarian crown, made to him in 1787 by Prussia at the instance of the Magyar malcontents, with the dry remark that he had no desire to be another "Winter King." In 1788 he took service in the Prussian army as major-general in active command of a regiment. As such he was present, with Goethe, at the cannonade of Valmy in 1792, and in 1794 at the siege of Mainz and the battles of Pirmasenz (Sept. 14) and Kaiserslautern (Oct. 28-30). After this, dissatisfied with the attitude of the Powers, he resigned; but rejoined on the accession of his friend King Frederick William III. to the Prussian throne. The disastrous campaign of Jena (1806) followed; on Oct. 14, the day after the battle, Weimar was sacked; and Charles Augustus, to prevent the confiscation of his territories, was forced to join the Confederation of the Rhine. From this time till after the Moscow campaign of 1812 his contingent fought under the French flag in all Napoleon's wars. In 1813, however, he joined the Grand Alliance, and at the beginning of 1814 took the command of a corps of 30,000 men operating in the Netherlands.

At the Congress of Vienna Charles Augustus was present in person and protested vainly against the narrow policy of the Powers in confining their debates to the "rights of the princes" to the exclusion of the "rights of the people." His services in the war of liberation were rewarded with an extension of territory and the title of grand-duke. He was the first of the German princes to grant a liberal constitution to his state under Article XIII. of the Act of Confederation (May 5, 1816); and his concession of full liberty to the press made Weimar for a while the focus of journalistic agitation against the existing order. Metternich dubbed him contemptuously "der grosse Bursche" for his patronage of the "revolutionary" Burschenschaften; and the celebrated "festival" held at the Wartburg by his permission in 1818 brought down upon him the wrath of the Great Powers. Charles Augustus was compelled to yield to the remonstrances of Prussia, Austria and Russia; the liberty of the press was again restricted in the grand-duchy, but, thanks to the good understanding between the grand-duke and his people, the régime of the Carlsbad Decrees pressed less heavily upon Weimar than upon other German States.

Charles Augustus died on June 14, 1828, and left two sons; Charles Frederick (d. 1853), by whom he was succeeded, and Bernhard, duke of Saxe-Weimar (1792-1862), who distinguished himself as commander of the Dutch troops in the Belgian campaign of 1830, and from 1847 to 1850 held the command of the forces in the Dutch East Indies. Bernhard's son, William Augustus Edward, known as Prince Edward of Saxe-Weimar (1823-1902), entered the British army, served with much distinction in the Crimean War, and became colonel of the 1st Life Guards and a field-marshal; in 1851 he contracted a morganatic marriage with Lady Augusta Gordon-Lennox (d. 1904), daughter of the 5th duke of Richmond and Gordon, who in Germany received the title of countess of Dornburg, but was granted the rank of princess in Great Britain by royal decree in 1866.

BIBLIOGRAPHY.—Karl August's Correspondence with Goethe was published in 2 vols. at Weimar in 1863. See F. X. Wegele, *Karl August, Grossherzog von Sachsen-Weimar* (Leipzig, 1850); W. Wachsmuth, *Herzog Karl August und Goethe* (Leipzig, 1911); W. CHARLES D'ORLÉANS: see ORLÉANS, CHARLES, DUKE OF.

CHARLES EDWARD (CHARLES EDWARD LOUIS PHILIP CASIMIR STUART) (1720-1788), English prince, called the "Young Pretender" and also the "Young Chevalier," was born at Rome on Dec. 31, 1720. He was the grandson of King James II. of England and elder son of James, the "Old Pretender," by whom (as James III.) he was created at his birth prince of Wales, the title he bore

among the English Jacobites during his father's lifetime. The young prince was educated at his father's miniature court in Rome, with James Murray, Jacobite earl of Dunbar, for his governor, and under various tutors, amongst whom were the learned Chevalier Ramsay, Sir Thomas Sheridan and the abbé Légoux. He learned the English, French and Italian languages, but his extant letters in English are singularly ill-spelt and illiterate. In 1734 he accompanied his cousin, the duke of Liria, afterwards duke of Berwick, on his expedition in aid of Don Carlos, and the boy of 13 shared with credit the dangers of the successful siege of Gaeta.

The Old Pretender calculated upon foreign aid in his attempts to restore the monarchy of the Stuarts; and the idea of rebellion unassisted by invasion or by support of any kind from abroad, was Charles Edward's own. Jacobite hopes mainly rested in France, and the warm sympathy which Cardinal Tencin, who had succeeded Fleury as French minister, felt for the Old Pretender resulted in a definite scheme for an invasion of England to be timed simultaneously with a prearranged Scottish rebellion. Charles was secretly despatched to Paris in January, 1744. A squadron under Admiral Roquefeuil sailed (Feb. 6) from Brest. Transports for 7,000 troops, to be led by Marshal Saxe, accompanied by the young prince, were in readiness to set sail for England. Meanwhile a strong English fleet appeared in the Downs, and a series of storms provided a probably welcome excuse to the French government for the cancellation of Marshal Saxe's orders. Louis declined to surrender Charles, but no official hospitality was offered him, and he lived in retirement. Charles Edward had made at Rome the acquaintance of Lord Elcho and of John Murray of Broughton; Murray visited him in Paris, and was told that he would come to Scotland in the summer of 1745, even though he came alone. His friends in Scotland saw no chance of success, and messengers, who do not seem to have reached him, were sent expressly to inform him. On July 13, 1745, he sailed from Nantes for Scotland on board the small brig "La Doutelle," which was accompanied by a war frigate, the "Elisabeth," provided by an Irishman at Dunkirk and laden with arms and ammunition. The latter fell in (July 20) with an English man-of-war, the "Lion," and had to return to France; Charles escaped during the engagement, and arrived on Aug. 3 off Erisca, a little island of the Hebrides. Receiving, however, but a cool reception from Macdonald of Boisdale, he set sail again and arrived at the Bay of Loch-na-nuagh on the west coast of Inverness-shire.

The Macdonalds of Clanranald and Kinloch Moidart, along with other chieftains, attempted in vain to dissuade him from the rashness of an unaided rising, but Lochiel and other chieftains, although they had sought to dissuade Charles from coming at all, now called out the clans. On Aug. 19, in the valley of Glenfinnan, the standard of James III. and VIII. was raised. Within a week about 2,000 men, mainly from the Macdonald clan, had joined him. Sir John Cope left Stirling for Inverness on Aug. 20 with 25 companies of foot, leaving the road to the south open to Charles. In the beginning of September the Jacobite army, reinforced by some accessions, notably by Lord George Murray, entered Perth. Crossing the Forth unopposed at the Fords of Frew and passing through Stirling and Linlithgow, he arrived within a few miles of Edinburgh, and on Sept. 16 a body of his skirmishers defeated the dragoons of Colonel Gardiner in what was known as the "Canter of Coltbrig." A few of Cameron's Highlanders having on the following morning, by a happy ruse, forced their way through the Canongate, Charles entered the city at noon. On the 18th he had himself proclaimed James VIII. of Scotland at the Market Cross and occupied Holyrood.

Cope had by this time brought his disappointed forces by sea to Dunbar. On the 20th Charles met and defeated him at Prestonpans, and returned to prosecute the siege of Edinburgh Castle, which, however, he raised on Gen. Guest's threatening to lay the city in ruins. He still hoped for French assistance definitely promised on Oct. 24 by secret treaty. In the beginning of November Charles left Edinburgh to invade England. He was at the head of at least 5,000 men; but the ranks were gradually thinned by the desertion of Highlanders, whose tradition had led them to consider war merely as a raid. Having passed through Kelso, on Nov. 9 he

laid siege to Carlisle which capitulated in a week. Manchester provided the prince with 150 recruits under Francis Towneley. On Dec. 4 he had reached Derby. Charles's officers were under no illusions about the strength of English resistance, but hoped that the advance might lead to intervention from France. When they found that the English counties did not rise they advised retreat. Two armies under English leadership were now in the field against Charles, one under Marshal Wade, whom he had evaded by entering England by the west, and the other under William, duke of Cumberland, who had returned from the Continent. On Dec. 6 Charles began his retreat northward. Closely pursued by Cumberland, he marched by way of Carlisle across the border, and at last stopped to invest Stirling Castle. At Falkirk, on Jan. 17, 1746, he defeated Gen. Hawley, who had marched from Edinburgh to intercept his retreat. The Jacobite army had been strengthened by Gordons, Mackintoshes and others, but the accessions were counter-balanced by desertions. A fortnight later, however, Charles raised the siege of Stirling, and after a weary march rested his troops at Inverness. Having taken Forts George and Augustus, and after varying success against the supporters of the government in the north, he at last prepared to face the duke of Cumberland, who had passed the early spring at Aberdeen. On April 8 the duke marched thence to meet Charles, whose little army, exhausted with a futile night march, half-starving, and broken by desertion, was completely worsted at Culloden on April 16, 1746.

This decisive defeat sealed the fate of Charles Edward and the house of Stuart. Hunted hither and thither Charles, upon whose head a reward of £30,000 had a year before been set, was for over five months relentlessly pursued by the troops and spies of the government. Disguised in female attire and aided by a passport obtained by the devoted Flora MacDonald, he passed through Skye, and towards the end of July took refuge in the cave of Coirraghoth in the Braes of Glenmoriston. In August he joined Lochiel and Cluny Macpherson, with whom he remained in hiding until the arrival of two French ships at Loch-na-nuagh, enabled him to sail for France. He reached Roscoff, near Morlaix, on Sept. 29, 1746. He remained in France for two years, but the Treaty of Aix-la-Chapelle entailed his expulsion from France. After his brother Henry's acceptance of a cardinal's hat in July 1747, he broke off communication with his father in Rome (who had approved the step), nor did he ever see him again. The enmity of the British government to Charles Edward made peace with France an impossibility so long as she continued to harbour the young prince. A condition of the Treaty of Aix-la-Chapelle, concluded in October 1748, was that every member of the house of Stuart should be expelled from the French dominions. Charles declared, he would not be bound by its provisions. But his indignation and persistent refusal to leave France were met at last with force; he was apprehended, imprisoned for a week at Vincennes, and on Dec. 17 conducted to the French border. He lingered at Avignon; but Pope Benedict XIV., alarmed by the threat of a bombardment of Civita Vecchia, advised the prince to withdraw. Charles quietly disappeared. For years Europe watched for him in vain. It is now established, almost with certainty, that he returned to the neighbourhood of Paris. In 1750 and again, it is thought, in 1754, he was in London, hatching futile plots and risking his safety for his hopeless cause, and even abjuring the Roman Catholic faith in order to further his political interests.

During the next ten years of his life Charles Edward's illicit connection with Miss Clementina Walkinshaw (d. 1802), whom he had first met at Bannockburn House while conducting the siege of Stirling, his imperious fretful temper, his drunken habits and debauched life, could no longer be concealed. He wandered over Europe in disguise, alienating his friends and crushing the hopes of his party; and in 1766, on returning to Rome at the death of his father, he was treated by Pope Clement XIII. with coldness, and his title as heir to the British throne was openly repudiated by all the great Catholic powers. It was probably through the influence of the French court, still intriguing against England, that the marriage between Charles (now self-styled count of Albany) and Princess Louise of Stolberg was arranged in 1772. The union proved childless and unhappy, and in 1780 the countess fled for

refuge from her husband's drunken violence to a convent in Florence. Later, the countess of Albany (*q.v.*) threw herself on the protection of her brother-in-law Henry, Cardinal York, at Rome, and a formal separation was arranged in 1784. Charles, lonely, ill, and evidently near death, now summoned to Florence his natural daughter, Charlotte Stuart, the child of Clementina Walkinshaw, born at Liège in October 1753 and hitherto neglected by the prince. Charlotte Stuart, who was declared legitimate and created duchess of Albany, tended her father for the remaining years of his life. She contrived to reconcile the two Stuart brothers, so that in 1785 Charles returned to Rome, where he died in the old Palazzo Muti on Jan. 30, 1788. He was buried in his brother's cathedral church at Frascati, but in 1807 his remains were removed to the *Grotte Vaticane* of St. Peter's. His daughter Charlotte died unmarried at Bologna in November, 1789.

CHARLES EMMANUEL I. (CARLO EMANUELE)

(1562-1630), duke of Savoy, succeeded his father, Emmanuel Philibert, in 1580. His three chief objects were the conquest of Geneva, of Saluzzo and of Monferrato. Saluzzo he succeeded in wresting from France in 1588. In 1590 he sent an expedition to Provence in the interests of the Catholic League, and followed it himself later, but the peace of 1593, by which Henry of Navarre was recognized as king of France, put an end to his ambitions. In the war between France and Spain Charles sided with the latter, with varying success. Finally, by the Peace of Lyons (1601), he gave up all territories beyond the Rhône, but his possession of Saluzzo was confirmed. His attempt to capture Geneva by treachery and with the help of Spain (the famous *escalade*) in 1602 failed completely. On the death in 1612 of Duke Francesco Gonzaga of Mantua, who was lord of Monferrato, Charles Emmanuel made a successful *coup de main* on that district. This arrayed the Venetians, Tuscany, the Empire and Spain against him, and he was obliged to relinquish his conquest. The terms of the peace of 1618 left him more or less in the *status quo ante*. In 1628 he was in alliance with Spain in the war against France and the French invaded the duchy. The duke fought desperately, but was taken ill at Savigliano and died in 1630. He was succeeded by his son Victor Amadeo I., while his third son Tommaso founded the line of Savoy-Carignano from which the present royal house of Italy is descended.

See E. Ricotti, *Storia della monarchia piemontese*, vols. iii. and iv. (Florence, 1865); T. Raulich, *Storia di Carlo Emanuele I.* (Milan, 1896-1902); G. Curti, *Carlo Emanuele I. secondo; più recenti studi* (Milan, 1894).

CHARLES MARTEL, "The Hammer," (c. 688-741), Frankish ruler, son of Pippin II., mayor of the palace, and Châlpaïda. Charles was baptized by St. Rigobert, bishop of Reims. At the death of his father in 714, Pippin's widow Plectrude claimed the government in Austrasia and Neustria in the name of her grandchildren, and had Charles thrown into prison. But the Neustrians threw off the Austrasian yoke and entered into an offensive alliance with the Frisians and Saxons. In the general anarchy Charles succeeded in escaping, defeated the Neustrians at Amblève, south of Liège, in 716, and at Vincy, near Cambrai, in 717, and forced them to come to terms. In Austrasia he wrested the power from Plectrude, and took the title of mayor of the palace, thus prejudicing the interests of his nephews. According to the Frankish custom he proclaimed a king in Austrasia in the person of the young Clotaire IV., but in reality Charles was the sole master—the entry in the annals for the year 717 being "*Carolus regnare coepit.*" Once in possession of Austrasia, Charles sought to extend his dominion over Neustria also. In 719 he defeated Ragenfrid, the Neustrian mayor of the palace, at Soissons, and forced him to retreat to Angers. Ragenfrid died in 731, and from that time Charles had no competitor in the western kingdom.

He obliged the inhabitants of Burgundy to submit, and disposed of the Burgundian bishoprics and countships to his *leudes*. In Aquitaine Duke Odo (*Eudes*) exercised independent authority, but in 719 Charles forced him to recognize the suzerainty of northern France, at least nominally. After the alliance between Charles and Odo on the field of Poitiers, the mayor of the palace left Aquitaine to Odo's son Hunald, who paid homage to him. Besides establishing a certain unity in Gaul, Charles saved it from a very great peril. In 711 the Arabs had conquered Spain. In 720 they crossed the Pyrenees, seized Narbonne, a dependency of the kingdom of the Visigoths, and advanced on Gaul. By his able policy Odo succeeded in arresting their progress for some years; but a new vali, Abdur Rahman, a member of an extremely fanatical sect, resumed the attack, reached Poitiers, and advanced on Tours, the holy town of Gaul. In Oct. 732 (just 100 years after the death of Mohammed) Charles gained a brilliant victory over Abdur Rahman, who was called back to Africa by the revolts of the Berbers and had to give up the struggle. This was the last of the great Arab invasions of Europe. After his victory Charles took the offensive, and endeavoured to wrest Narbonne from the Muslims. Although he was not successful in his attempt to recover Narbonne (737), he destroyed the fortresses of Agde, Béziers and Maguelonne, and set fire to the amphitheatre at Nîmes. He subdued also the Germanic tribes; annexed Frisia, where Christianity was beginning to make progress; put an end to the duchy of Alemannia; intervened in the internal affairs of the dukes of Bavaria; made expeditions into Saxony; and in 738 compelled some of the Saxon tribes to pay him tribute. He also gave St. Boniface a safe conduct for his missions in Thuringia, Alemannia and Bavaria.

During the government of Charles Martel important changes appear to have been made in the internal administration. Under him began the great assemblies of nobles known as the *champs de Mars*. To attach his *leudes* Charles had to give them church lands as *precarium*, and this had a very great influence in the development of the feudal system. It was from the *precarium*, or ecclesiastical benefice, that the feudal fief originated. Vassalage, too, acquired a greater consistency at this period, and its rules began to crystallize. Under Charles occurred the first attempt at reconciliation between the papacy and the Franks. Pope Gregory III., menaced by the Lombards, invoked the aid of Charles (739), sent him a deputation with the keys of the Holy Sepulchre and the chains of St. Peter, and offered to break with the emperor and Constantinople, and to give Charles the Roman consulate (*ut a partibus imperatoris recederet et Romanum consulatum Carolo sanciret*). This proposal, though unsuccessful, was the starting point of a new papal policy. Since the death of Theuderich IV. in 737 there had been no king of the Franks. In 741 Charles divided the kingdom between his two sons, as though he were himself master of the realm. To the elder, Carloman, he gave Austrasia, Alemannia and Thuringia, with suzerainty over Bavaria; the younger, Pippin, received Neustria, Burgundy and Provence. Shortly after this division of the kingdom Charles died at Quierzy on Oct. 22, 741, and was buried at St. Denis. The characters of Charles Martel and his grandson Charlemagne offer many striking points of resemblance. Both were men of courage and activity, and the two men are often confused in the *chansons de geste*.

Beugnot, "Sur la spoliation des biens du clergé attribuée à Charles Martel," in the *Mém. de l'Acad. des Inscr. et Belles-Lettres*, xix. (1853); U. Chevalier, *Bio-bibliographie* (2nd ed. 1904). (C. Fr.)

CHARLES CITY, a city of northern Iowa, U.S.A., on Cedar river; the county seat of Floyd county. It is on Federal highways 18 and 218 and served by the Chicago, Milwaukee, St. Paul and Pacific, Illinois Central, and Charles City Western railways. The population in 1930 Federal census was 8,039. It is in a rich agricultural region; has abundant water-power; manufactures tractors, furnaces, air-compressors, hay-ricks, tanks, office equipment, children's hosiery and other articles; and has extensive nurseries, specializing in evergreens and roses. The city was founded in 1850 and incorporated in 1860.

CHARLESTON, a city of eastern Illinois, U.S.A., on the Nickel Plate and the Big Four railways, 45m. W. of Terre Haute; the county seat of Coles county. The population in 1920 was 6,615; 1930 it was 8,012. It is in the midst of the broom-corn belt, and has broom and shoe factories and railroad shops. The Eastern Illinois State Normal School, established here in 1895, has an enrolment of over 2,000. Charleston was settled about 1835, and was incorporated in 1839. One of the Lincoln-Douglas debates was held here in 1858.

CHARLESTON, the largest city of South Carolina, U.S.A., and an important South Atlantic seaport, on a narrow peninsula between the Cooper and the Ashley rivers, at the head of the bay formed by their confluence, 7m. from the ocean; the county seat of Charleston county, headquarters of the customs district of South Carolina, and the official port of the State. It is on Federal highways 17 and 78; and is served by the Atlantic Coast Line, the Seaboard Air Line and the Southern railways, and by coastwise, inter-coastal and foreign steamship lines. The population in 1920 was 67,957 (47.6% negroes), and was 62,265 in 1930 by the Federal census of that year. The city covers 5.12sq.m., nowhere rising more than 8 or 10ft. above the rivers, has 9m. of water-front within the city limits and 8m. outside. On islands in the harbour are Forts Sumter, Moultrie (where the U.S. army maintains a unit), Johnson (now the quarantine station), Ripley and Castle Pinckney. North of the city, on the west bank of Cooper river, is a first-class navy yard, which has an aviation field and a dry dock 575ft. long. Still farther north (10.4m. above the custom-house) are the port terminals, constructed by the United States during the World War as an army supply base, and now leased by the Port Utilities commission of Charleston from the U.S. shipping board.

The spacious harbour, almost landlocked, and protected by two converging stone jetties (15,443 and 19,104ft. long), accommodates vessels with a draught of 30 feet. Its commerce in 1926 amounted to 3,246,174 tons of cargo, valued at \$209,907,448, and floated logs and lumber valued at \$767,837. In-bound traffic consists largely of oil, gasoline (petrol) and materials for fertilizer; out-bound, of petroleum products, cross-ties, coal from Virginia and West Virginia, cotton and cotton goods and tobacco from the Carolinas and Georgia. Trade with foreign countries in 1926 represented a value of \$36,304,294 in exports and \$11,663,403 in imports. Charleston is an important centre for the distribution and refining of oil, and it has large fertilizer plants. Other leading manufactures are woven asbestos, cotton-bagging, iron work and various articles of wood. The city is a bunkering and repair station for both commercial and naval vessels; headquarters of the 6th naval district, of the south-eastern division of the Engineering Corps of the army, and of the 6th lighthouse district; and a market for the agricultural products (notably vegetables, tobacco and cotton) and the pine and hardwood of the State, and for the oysters, crabs, shrimps and fish caught off the adjacent islands.

Charleston has a unique charm and beauty, compounded of natural advantages of situation, historic associations, sub-tropical trees and flowers, marvellous old gardens glimpsed through wrought-iron gates, and numerous survivals of colonial architecture, with balustraded steps, pillared porticos and spacious verandas. A city plan and zoning regulations are in process of formulation which, while providing conveniently for industrial and residential expansion, will preserve the picturesque and historic old sections and develop the entire Ashley river water-front as a parkway and a site for public and semi-public buildings, with the beautiful memorial bridge of concrete and steel and the new plant of the Citadel adjoining Hampton park as features of the development. At the lower end of the peninsula is the Battery, or White Point gardens, planted with live-oaks and palmettos. Beach resorts are developed on outlying islands which formerly (until 1718) were the haunts of pirates. The Magnolia gardens, up the Ashley, are a monument to the exquisite taste and poetic imagination of the Rev. John Grimké Drayton, who created them when in the 1840's his physician ordered him to lead an outdoor life. At Middleton place, farther up the river, one wing of the great Tudor mansion still stands, and there are gardens which had

renown in England in the 18th century. Among the many educational institutions of the city are the College of Charleston, chartered in 1785 and taken over by the city in 1837 (the first municipal college in the country); the South Carolina medical college, a State institution founded in 1824; and the Citadel, the military college of South Carolina, created by the legislature in 1842. The Charleston library was founded in 1748; the museum in 1773.

The first English settlement in South Carolina, named after the reigning king, was made at Albemarle Point on the west bank of the Ashley in 1670, but in 1672 a new town was begun on the present site, and the seat of government was moved to it in 1680. It soon became the largest and wealthiest settlement south of Philadelphia; the brilliant social and cultural centre of the province and later of the State; the home of the Pinckneys, the Rutledges, the Gadsdens, the Laurenses and many other notable families. Magnificent estates were developed in the surrounding country. The port shipped one specialty after another—rice, indigo, tobacco, lumber, cotton—before entering on its present phase as a more general cargo port. Charleston was the capital of the State until 1790. Until 1783 it was governed by ordinances passed by the legislature and enforced partly by provincial officials and partly by the churchwardens. The city charter of 1783, with many amendments, is still in force. In 1850 the population was 42,985, ranking Charleston 15th among the cities of the United States.

Charleston was attacked by a combined fleet of Spanish and French in 1706; withstood attacks from the British in 1776 and in 1779, but in 1780 was captured from the land side by Sir Henry Clinton and became the base of operations in the Carolinas, remaining under military rule until Dec. 14, 1782. It was the centre of the nullification movement of 1832-33. The bombardment and capture of Ft. Sumter (April 12-13, 1861) by the South Carolinians marked the beginning of the Civil War. From 1862 to 1865 Charleston was almost continually under siege by the Federal naval and military forces, and on Feb. 17, 1865, the Confederates evacuated the city, after burning large stores of cotton and other supplies to keep them from coming into possession of the enemy. Charleston was devastated by hurricanes in 1699, in 1752 and in 1854; by epidemic in 1699 and in 1854; by fire in 1740; and by an earthquake on Aug. 31, 1886, which damaged 90% of the buildings. Since the World War the foreign commerce of the port has increased greatly, advancing it from 34th to 15th place among the ports of the country.

See (for the best history of Charleston) William A. Courtenay, *Charleston, S.C.: The Centennial of Incorporation* (Charleston, 1884). Sketches of many of the historic buildings are included in *Charleston, South Carolina*, edited by Albert Simons and Samuel Lapham, Jr. (Press of the American Institute of Architects, 1927).

CHARLESTON, the capital of West Virginia, U.S.A., on the Kanawha river at the mouth of the Elk, south-west of the centre of the State; the county seat of Kanawha county. It is on Federal highways 21 and 60; and is served by the Baltimore and Ohio, the Chesapeake and Ohio and the New York Central railways, and by river steamers. The population in 1920 was 39,608, of whom 1,354 were foreign-born white and 4,502 were negroes; and was 60,408 in 1930 Federal census. The city has a fine location on high level land above the river. It is an important industrial centre, and a shipping point for the natural resources of the Kanawha valley, including large quantities of coal, oil, hardwood and salt. Natural gas in abundance is found in the vicinity. The factory output within the city limits in 1925 (including furniture, steel, glass and heavy chemicals) was valued at \$8,883,461. The U.S. Government has armour-plate, gun-forging and projectile plants here, which represent an investment of \$100,000,000. The city's assessed valuation of property in 1927 was \$104,493,008. A magnificent new capitol was under construction in 1928 to replace the one built in 1880. Charleston was settled soon after the Revolution, and was incorporated in 1794. It was on the route of migration to the Ohio valley, and became a transfer and shipping centre, but its industrial importance is comparatively recent, following the development of West Virginia coal-fields and other natural resources. In 1870, when it was chartered as

a city, the population was only 3,162; in 1900, 11,099. It has been the capital of the State since 1870, except for the decade 1875-85.

CHARLESTOWN, formerly a separate city of Middlesex county, Massachusetts, U.S.A., but since 1874 a part of the city of Boston, with which it had long before been in many respects practically one. It is situated on a small peninsula on Boston harbour, between the mouths of the Mystic and Charles rivers; the first bridge across the Charles, built in 1786, connected Charlestown and Boston. A United States navy yard (1800), occupying about 87ac., and the Massachusetts state prison (1805) are here; the old burying-ground contains the grave of John Harvard and that of Thomas Beecher, the first American member of the famous Beecher family; and there is a soldiers' and sailors' monument (1872), designed by Martin Milmore. Charlestown was founded in 1628 or 1629, being the oldest part of Boston, and soon rose into importance; it was organized as a township in 1630, and was chartered as a city in 1847. Within its limits was fought, on June 17, 1775, the battle of Bunker Hill (*q.v.*), when Charlestown was almost completely destroyed by the British. The Bunker Hill monument commemorates the battle. The original territory of the township was very large, and from parts of it were formed Woburn (1642), Malden (1649), Stoneham (1725), and Somerville (1842); other parts were annexed to Cambridge, to Medford and to Arlington. S. F. B. Morse, the inventor of the electric telegraph, was born here; and Charlestown was the home of Samuel Dexter (1761-1816), an eminent lawyer, secretary of war in the cabinet of President John Adams, and of Oliver Holden (1765-1831), a composer of hymn-tunes, including "Coronation."

See R. Frothingham, *History of Charlestown* (1845), covering 1629-1775; J. F. Hunnewell, *A Century of Town Life . . . 1775-1887* (1888); Timothy T. Sawyer, *Old Charlestown* (1902); and H. H. Sprague, *The Founding of Charlestown by the Spragues* (1910).

CHARLET, NICOLAS TOUSSAINT (1792-1845), French designer and painter, more especially of military subjects, was born in Paris on Dec. 20, 1792, and died there on Oct. 30, 1845. The son of a dragoon in the Republican army, he was educated at the Lycée Napoléon, and served in the National Guard in 1814. In 1816 Charlet entered the atelier of Gros, and soon began issuing the first of those lithographed designs of subjects drawn from the Napoleonic wars which eventually brought him renown. Lithographs (about 2,000 altogether), water-colours, sepia-drawings, numerous oil sketches, and a few etchings followed one another rapidly, and he exhibited some large canvases. His best work was the "Episode in the Retreat from Russia," exhibited in the salon of 1836.

See De la Combe, *Charlet, sa vie, ses oeuvres* (1856).

CHARLEVILLE, a town of north-eastern France, in the department of Ardennes, 50 m. N.E. of Reims. Pop. (1926) 21,700. Charleville is situated within a bend of the Meuse on its left bank, opposite Mézières, with which it is united by a suspension bridge. The town was founded in 1606 by Charles III. (Gonzaga), duke of Nevers, afterwards duke of Mantua, and is laid out on a definite plan. The Place Ducale is a large square surrounded by old houses. On the right bank of the Meuse is Mont Olympe, with the ruins of a fortress dismantled under Louis XIV. Charleville, which shares with Mézières the administrative institutions of the department of Ardennes, has tribunals of first instance and of commerce, a chamber of commerce, and a board of trade-arbitrators. Its chief industries are metal-founding, the manufacture of iron goods and the making of bricks. Brushes and clay pipes are also made.

CHARLEVOIX, PIERRE FRANÇOIS XAVIER DE (1682-1761), French Jesuit traveller and historian, was born at St. Quentin on Oct. 29, 1682. At 16 he entered the Society of Jesus; and at 23 was sent to Canada, where he remained for four years as professor at Quebec. In 1720-22, under orders from the regent, he visited America for the second time, and went along the Great Lakes and down the Mississippi. He died at La Flèche on Feb. 1, 1761.

Among his works are: *Histoire de l'Isle Espagnole ou de Saint Domingue* (1730), based on manuscript memoirs of P. Jean-Baptiste

le Pers and original sources; *Histoire de Paraguay* (1756); *Vie de la Mère Marie de l'Incarnation, institutrice et première supérieure des Ursulines de la Nouvelle France* (1724); *Histoire et description générale de la Nouvelle France* (1744; in English 1769; tr. J. G. Shea, 1866-72), a work of capital importance for Canadian history.

CHARLEVOIX, a city of Michigan, U.S.A., on Lake Michigan, with Lake Charlevoix on its eastern boundary and Round lake in the centre of the town; a port of entry and the county seat of Charlevoix county. It is on Federal highway 31, and is served by the Pere Marquette railway and by lake steamers during navigation season. The population in 1930 was 2,247. Charlevoix is one of the most popular summer resorts of the State, and has cement and lime works and a considerable fishing industry. The commerce of the port declined from 234,120 tons in 1910 to 24,882 in 1925. Charlevoix was settled about 1866, and was incorporated as a city in 1905.

CHARLOTTE (1840-1927), empress of Mexico, only daughter of Leopold I., king of Belgium, and Louise, princess of Orleans, was born at Laeken, near Brussels, on June 7, 1840. She married in 1857 the Archduke Maximilian of Austria, and went with him to Mexico in 1864, when he accepted the Mexican crown. When it became evident in 1866 that Maximilian's position was untenable, she was sent by her husband to Europe to implore the assistance of Napoleon III., who had decided to withdraw the French troops from Mexico. In this mission she failed, and foreseeing a catastrophe (Maximilian was shot in 1867) she went out of her mind (Sept. 1866). Charlotte was placed by her family under care in a Belgian château and survived until January 19, 1927. (See also MAXIMILIAN.)

See Count Corti, *Maximilian und Carlotta von Mexico* (1924, 2 vols.).

CHARLOTTE, a city of Michigan, U.S.A., 18m. S.W. of Lansing; on Federal highway 27, and served by the Grand Trunk and the Michigan Central railways; the county seat of Eaton county. The population in 1920 was 5,126; 1930 it was 5,307. It has varied manufacturing industries, and is the trade centre of a rich agricultural and dairying region, which raises large quantities of beans.

CHARLOTTE, a city in southern North Carolina, U.S.A., 175m. S.W. of Raleigh; the county seat of Mecklenburg county. It is on Federal highways 21, 74 and 170; and is served by the Norfolk Southern, the Piedmont and Northern, the Seaboard Air Line and the Southern railways. In 1900 the population was 18,091; in 1920, 46,338 (34.6% negroes); and in 1930 it was 82,675 by Federal census of that year. Cotton, tobacco, peanuts and truck crops are grown in the vicinity. Charlotte is at the heart of the hydro-electric development and the textile industry of the southern Piedmont. Many northern manufacturers of machinery, dye-stuffs and other items needed for the equipment of cotton-mills have branches here, and it is a distributing point for automobiles and their accessories. Bank debits to individual accounts in 1926 amounted to \$611,726,000. The assessed valuation of property in 1926 was \$115,624,655. Within the city limits are 26 textile plants, with 226,650 spindles, 5,331 looms and 239 knitting-machines. The output of the city's factories of all kinds (making 200 diversified products) was valued in 1925 at \$54,416,558. Printing and publishing is an important industry.

Charlotte is the seat of Queen's college for women, originally chartered by the colonial legislature in 1771; and of the Johnson C. Smith university for negroes (formerly Biddle university) founded in 1867. The city was settled about 1750, and incorporated in 1768. It has a commission form of government. A monument in front of the court-house commemorates the signing of the "Mecklenburg Declaration of Independence" in May 1775. For a brief period in 1780 the city was occupied by Cornwallis, who nicknamed it "the hornets' nest." Later it became the principal base of Gen. Greene's operations. Andrew Jackson and James K. Polk were born near by, and here on April 10, 1865, Jefferson Davis convened his cabinet for its last meeting.

"**CHARLOTTE DUNDAS**," the name given by her inventor to the first practical steamship. William Symington, in 1802, built the tug "Charlotte Dundas," a paddle-wheel steamer, and successfully tried her on the Forth and Clyde Canal; the name

was a compliment to the family of Lord Dundas, who suggested the experiment, and the boat was built for the Forth and Clyde Canal Company. The motive-power employed was a double-acting condensing engine constructed by James Watt. The engine was fixed horizontally and actuated the crank of a stern-shaft which carried the paddle-wheel. The "Charlotte Dundas" managed to tow two vessels with a burden of 140 tons, in the teeth of a strong

THE "CHARLOTTE DUNDAS," THE FIRST PRACTICAL STEAMBOAT, BUILT IN 1802 BY WILLIAM SYMINGTON AND DRIVEN BY AN ENGINE SUPPLIED BY JAMES WATT

wind, at the rate of $3\frac{1}{4}$ m. an hour. Five years later, the American Robert Fulton, who had witnessed the "Charlotte Dundas" experiment, built the famous "Clermont" on the River Hudson.

CHARLOTTENBURG, a town incorporated in the Greater Berlin scheme of 1912 (which came into full operation in 1920), in the republic of Prussia, on the river Spree; its earlier name was Lietzenburg. The central part of the town is connected with Berlin by an avenue, the Charlottenburger Chaussée. The Schloss, built in 1696 for the electress Sophie Charlotte, queen of the elector Frederick, after whom the town was named, contains a collection of antiquities and paintings. In Charlottenburg is the Physikalisch-technische Reichsanstalt, a state institution for the carrying out of scientific experiments and measurements, and for testing instruments of precision, materials, etc. In addition to the famous royal porcelain manufactory, there are many industries, notably iron-works, grouped along the banks of the Spree.

CHARLOTTESVILLE, a city in the beautiful Piedmont region of Virginia, U.S.A., on the Rivanna river, 70 m. W.N.W. of Richmond; the county seat of Albemarle county, but administratively independent of it. It is served by the Chesapeake and Ohio, and the Southern railways. The population in 1920 was 10,688, of whom 2,947 were negroes, and was 15,245 in 1930 Federal census. It is the seat of the University of Virginia (*q.v.*) and the trade centre of an agricultural district noted for its fine apples and peaches. There is a law-book publishing house, and several manufacturing industries, with an output valued in 1925 at \$1,527,733.

On a hill 3 m. E., visible from all parts of the city, is Monticello, the home of Thomas Jefferson from 1770 until his death, now a national memorial. The house, in a setting of great beauty, was planned by Jefferson and built under his personal supervision. It is one of the most interesting and picturesque examples of colonial architecture, and embodies many ingenious devices of its versatile designer. His grave is on the estate. Mirador, the birthplace of Lady Astor, is about 20 m. W. of the city. The site of Charlottesville was a part of the Castle Hill estate of Thomas Walker (1715-94). The town (named after Queen Charlotte) was incorporated in 1762. In 1888 it was chartered as a city, independent of the county. It has a commission manager form of government. In 1779-80 about 4,000 of Burgoyne's troops, surrendered under the Convention of Saratoga, were quartered here. In June 1781, Tarleton raided the town and vicinity, destroying the public records and nearly capturing Jefferson. Jefferson owed his escape to the warning brought by a young Virginian soldier, Jack Jouett, who rode 40 m. across rough country through the night to outstrip Tarleton, after accidentally getting a clue to his plans through conversation overheard at a tavern.

CHARLOTTETOWN, the capital of the province of Prince Edward Island, Canada, situated in Queen's county, on Hillsborough river. Pop. (1931) 12,361. It has a good harbour, and the river is navigable by large vessels for several miles. The export trade of the island centres here, and the city has regular communication by steamer with the chief American and Canadian ports and with Newfoundland. Besides the Government buildings and the court-house, it contains the Prince of Wales college, supported by the province, the Roman Catholic college of St. Dunstan's and a normal school; among its manufactures are woollen goods, lumber, canned goods and foundry products; its fisheries are extensive and important. The head office and workshops of the Prince Edward Island railway are situated here. The town was founded in 1750 by the French under the name of Port la Joie, but under British rule changed its name in honour of the queen of George III.

CHARM, an incantation, verses sung with supposed magical results, hence anything possessing powers of bringing good luck or averting evil, particularly articles worn with that purpose, such as an amulet. It is thus used of small trinkets attached to bracelets or chains. The word is also used, figuratively, of fascinating qualities of feature, voice or character. It is derived through the Fr. from the Lat. *carmen*, a song.

CHARMES, FRANCIS (1848-1916), French journalist and politician, was born at Aurillac, Cantal, on April 21, 1848. He was educated at Aurillac and at the lycées of Clermont-Ferrand and Poitiers. He was editor of the *Journal des Débats* from 1872 to 1880, and from 1889 to 1907. During the interval he served in the political department of the Foreign office. He sat in the chamber of deputies from 1881 to 1885 and from 1889 to 1898, and in 1900 became a senator. Charmes is, however, best known for his connection with the *Revue des Deux Mondes*. In 1893 he began his famous political writings in the *Revue*, and in 1907 became its editor. His literary and political articles were one of the features of French literary history during the last years of the 19th century. He died in Paris on Jan. 4, 1916.

CHARMEUSE. In textiles, the proprietary name for a silk dress fabric of light and delicate texture suitable for gowns, party wraps, and such like garments for purely dress purposes, and for which strength and durability are not essential qualities. This fabric has a rich and more lustrous appearance on the face side than on the reverse side, which latter is of a more subdued lustre. This difference in lustre results from the particular weave structure of the fabric, and the difference between the character, counts and number of warp and weft threads employed. A typical example of charmeuse consists of a very light texture developed by the 12-end warp-face satin weave, and produced from a grenadine organdie warp, and a two-ply pure schappe silk weft, or else crêpe de Chine twist for the warp, and schappe silk for the weft. Charmeuse is also sometimes developed by employing the warp-face satin weave in combination with a light voile foundation texture. This is produced by introducing two picks of fine and hard-twisted weft alternately with two picks of schappe silk weft. In this structure the fine picks of weft interweave with the warp threads in the plain weave order, that is, under and over successive warp threads, thereby serving to reinforce the satin weave texture which would otherwise be very weak and flimsy. After weaving, the fabric is piece-dyed and finished with the characteristic soft finish to which it owes its good draping qualities. (H. N.)

CHARNAY (CLAUDE JOSEPH), DÉSIRÉ (1828-1915), French traveller and archaeologist, was born in Fleurie (Rhône), studied at the Lycée Charlemagne, and in 1850 became a teacher in New Orleans, Louisiana. He travelled in Mexico, under a commission from the French ministry of education, in 1857-61; in Madagascar in 1863; in South America, particularly Chile and Argentina, in 1875; and in Java and Australia in 1878. In 1880-83 he again visited the ruined cities of Mexico. Pierre Lorillard of New York contributed to defray the expense of this expedition, and Charnay named a great ruined city near the Guatemalan boundary line Ville Lorillard in his honour. Charnay went to Yucatan in 1886. His works include: *Le Mexique, souvenirs et impressions de voyage* (1863), and *Les Anciennes Villes*

du Nouveau Monde (1885; Eng. trans. 1887). He elaborated a theory of Toltec migrations and considered the prehistoric Mexican to be of Asiatic origin, because of observed similarities to Japanese architecture, Chinese decoration, Malaysian language and Cambodian dress, etc.

See *Recueil de Voyages*, etc., vol. xix. (1903).

CHARNEL HOUSE. A place for the storage of human bones, specifically that rendered necessary by the fact that many crowded mediaeval cemeteries were used again and again, so that each new burial unearthed the bones of people long dead. Charnel houses were sometimes situated in church crypts, and sometimes as separate buildings in the church yards; chantry chapels were occasionally added. (See Viollet-le-Duc, *Dictionnaire raisonné de l'architecture*, s.v. *ossuaire*.)

CHARNOCK, JOB (d. 1693), English founder of Calcutta, went out to India in 1655 or 1656, apparently not in the East India Company's service, but soon joined it. He was stationed at Cossimbazar, and subsequently at Patna. In 1685 he became chief agent at Hugli. Being besieged there by the Mogul viceroy of Bengal, he put the company's goods and servants on board his light vessels and dropped down the river 27 m. to the village of Sutanati, a place well chosen for the purpose of defence, which occupied the site of what is now Calcutta. It was only, however, at the third attempt that Charnock finally settled down at this spot, and the selection of Calcutta as the capital of India was entirely due to his stubborn resolution.

CHARNOCK or CHERNOCK, ROBERT (c. 1663–1696), English conspirator, was educated at Magdalen college, Oxford, becoming a fellow of his college and a Roman Catholic priest. When in 1687 the dispute arose between James II. and the fellows of Magdalen over the election of a president Charnock favoured the first royal nominee, Anthony Farmer, and also the succeeding one, Samuel Parker, bishop of Oxford. Almost alone among the fellows he was not driven out in Nov. 1687, and he became dean and then vice-president of the college under the new régime, but was expelled in Oct. 1688. Residing at the court of the Stuarts in France, or conspiring in England, Charnock and Sir George Barclay appear to have been implicated in the attempt to kill William III. near Turnham Green, in Feb. 1696. Barclay escaped, but Charnock was arrested, was tried and found guilty, and was hanged on March 18, 1696.

CHARNOCKITE, in petrology a series of igneous rocks (originally described by Sir T. H. Holland) from Madras presidency, southern India, and forming a well-defined petrographic province of Archaean age. The name is derived from that of the founder of Calcutta, Job Charnock, whose tombstone is made of a typical member of the series. The series includes a wide range of rock types from ultrabasic pyroxenites through intermediate types—norites and quartz-hypersthene-diorites—to acid pyroxene-granites. The term charnockite is often specifically reserved for the acid hypersthene-granite. One of the distinguishing features of the series is the recurrence in many members of a strongly pleochroic red-to-green hypersthene. The typical members of the series, however, show other peculiar mineralogical features, namely the development of *schiller* structures, from the presence of minute plate or rod shaped enclosures disposed parallel to definite crystallographic planes or axes. The optical effect of these enclosures is seen in the blue opalescence of the quartz, the milky shimmer of the feldspar and the bronzelike lustre of the rhombic pyroxene. Myrmekitic, micropertthitic and antiperthitic structures are common in the feldspars. In the soda-lime feldspars there is a striking tendency to absence of the usual twinning lamellae. The members of the charnockite series frequently show a banded or gneissic structure, now usually interpreted as a flow banding, due to movement during the epoch of crystallization. Chemically the series is distinctly subalkaline, with a dominance of iron oxides over magnesia and lime.

The various members are of widespread distribution and great petrological importance. In southern India they occur in the Nilgiri hills, the Shevaroy and the western Ghats, extending southward to Cape Comorin and reappearing in Ceylon. They occur in the Archaean shield of Western and South Australia and

in Adélie Land, Antarctica. Similar rocks are known from the Ivory coast of West Africa, the eastern part of Ellesmere Land; form the Cortlandt series near Peekskill, N. Y., and recur at other localities in the eastern United States and Canada. The most noteworthy occurrences in the northern hemisphere are found in south-western and western Norway, at East Kersund and Soggendal, and over a large area in the Bergen and Jotunheimen districts. The majority of the known occurrences of the charnockite series are of Archaean age, but it is probable that the anorthosite-charnockite series of the Bergen-Jotunheimen districts is of lower Palaeozoic (Caledonian) age. (C. E. T.)

CHARWOOD FOREST, an upland tract in north Leicestershire (q.v.), England, south-west of Loughborough. It is in great part barren, though there are extensive tracts of woodland. Over 6,000 ac. are at a height exceeding 600 ft.; the loftiest point, Bardon Hill, is 912 ft.

CHAROLLES, a town of east-central France, capital of an arrondissement in the department of Saône-et-Loire, at the confluence of the Semence and Arconce, 39 m. W.N.W. of Mâcon. Pop. (1926) 2,987.

Charolles was the capital of Charolais which from the early 14th century gave the title of count to its possessors. The ruins of their castle are on a hill near the town. In 1327 the countship passed by marriage to the house of Armagnac, and in 1390 it was sold to Philip of Burgundy. After the death of Charles the Bold it was seized by Louis XI. of France, but in 1493 it was ceded by Charles VIII. to Maximilian of Austria. Ultimately passing to the Spanish kings, its possession became disputed, until in 1684 it was assigned to Condé, a creditor of the king of Spain. It was united to the French crown in 1771.

There are stone quarries in the vicinity; the town manufactures pottery, and is the centre for trade in the famous breed of Charolais cattle and has also a timber trade. It has a sub-prefecture and tribunals of primary instance and commerce.

CHARON, in Greek mythology, the son of Erebus and Nyx (Night). It was his duty to ferry over the Styx (or Acheron) those souls of the deceased who had duly received the rites of burial, in payment for which service he received an obol, which was placed in the mouth of the corpse. He is probably a product of popular belief, not mentioned in Homer or Hesiod. He is represented as a morose and grisly old man. In Etruscan he is called Charun, and appears as a death-demon, armed with a hammer. Finally he came to be regarded as the image of death and the world below. As such he survives in the Charos or Charontas of the modern Greeks.

See the classical dictionaries, especially Roscher's *Lexikon*, s.v.

CHARONDAS, a celebrated lawgiver of Catina in Sicily. His date is uncertain. Some make him a pupil of Pythagoras (c. 580–504 B.C.); but all that can be said is that he was earlier than Anaxilaus of Rhegium (494–476), who abolished his laws, previously in use at Rhegium. His laws, originally written in verse, were adopted by the other Chalcidic colonies in Sicily and Italy. According to Aristotle there was nothing special about these laws, except that Charondas introduced actions for perjury; but he speaks highly of the precision with which they were drawn up (*Politics*, ii. 12). The legal fragments attributed to him by Stobaeus and Diodorus are of late (neo-Pythagorean) origin.

See Bentley, *On Phalaris*, which (according to B. Niese, s.v. in Pauly, *Realencyklopädie*) contains the best account of Charondas; A. Holm, *Geschichte Siciliens*, i.; F. D. Gerlach, *Zaleukos, Charondas, und Pythagoras* (1858); also art. GREEK LAW.

CHARPENTIER, FRANÇOIS (1620–1702), French archaeologist and man of letters, was born in Paris. In his *Excellence de la langue française* (1683) he anticipated Perrault in the famous academical dispute concerning the relative merit of the ancients and moderns. He is credited with a share in the production of the magnificent series of medals that commemorate the principal events of the age of Louis XIV.

CHARRIÈRE, ISABELLE DE (1740–1805), Swiss author, was Dutch by birth, her maiden name being van Tuyll van Seeroskerken van Zuylen. She married in 1771 her brother's tutor, Saint-Hyacinth de Charrière, and settled with him at

Colombier, near Lausanne. Her *Lettres neuchâteloises* (Amsterdam, 1784) offer a simple and attractive picture of French manners. This, with *Caliste, ou lettres écrites de Lausanne* (2 vols. Geneva, 1785-88), was analysed and highly praised by Sainte-Beuve in his *Portraits de femmes* and in vol. iii. of his *Portraits littéraires*. She wrote a number of other novels, and some political tracts; but is perhaps best remembered by her liaison with Benjamin Constant (q.v.) between 1787 and 1796.

Her letters to Constant were printed in the *Revue suisse* (April 1844), her *Lettres-Mémoires* by E. H. Gaullieur in the same review in 1857, and all the available material is utilized in a monograph on her and her work by P. Godet, the editor of her *Oeuvres complètes* (3 vols. 1907-09), in his *Madame de Charrière et ses amis* (2 vols., Geneva, 1906).

CHARRON, PIERRE (1541-1603), French philosopher, was born in Paris. He entered the Church, and was appointed preacher in ordinary to Marguerite, wife of Henry IV. of Navarre. At Bordeaux he met Montaigne, whose intimate friend he became.

In 1594 Charron published (at first anonymously, afterwards under the name of "Benoit Vaillant, Advocate of the Holy Faith," and also, in 1594, in his own name) *Les Trois Vérités*, in which he seeks to prove that there is a God and a true religion, that the true religion is the Christian, and that the true Church is the Roman Catholic. It is chiefly an answer to the famous Protestant work entitled *Le Traité de l'Église* by Du Plessis Mornay. It was followed in 1600 by *Discours chrestiens*, a book of very eloquent sermons. In 1601 Charron published at Bordeaux the famous *De la sagesse*, a complete popular system of moral philosophy. Usually it is coupled with the *Essays* of Montaigne, to which the author is under very extensive obligations in it. Charron suddenly stood forth as the representative of the most complete intellectual scepticism. The *De la sagesse* brought upon its author the most violent attacks. It received, however, the warm support of Henry IV. and of the president Pierre Jeannin (1540-1622).

Charron's psychology is sensationalist. With sense all our knowledge commences. The soul, located in the ventricles of the brain, is affected by the temperament of the individual; the dry temperament brings intelligence; the moist, memory; the hot, imagination. The immortality of the soul is the most universal of beliefs, but the most feebly supported by reason. As to man's power of attaining truth, he plainly declares that none of our faculties enable us to distinguish truth from error. On a pessimistic view of human nature Charron founded a moral system that may be summarized as follows: Man comes into the world to endure; let him endure then, and that in silence. Our compassion should be like that of God, who succours the suffering without sharing in their pain. Avoid vulgar errors; cherish universal sympathy. Let no passion or attachment become too powerful for restraint. Follow the customs and laws which surround you. Morality has no connection with religion. Reason is the ultimate criterion.

Charron holds that all religions grow from small beginnings and increase by popular contagion; all teach that God is to be appeased by prayers, presents, vows, but especially, and most irrationally, by human suffering. Each is said by its devotees to have been given by inspiration. In fact, however, a man is a Christian, Jew, or Mohammedan, before he knows he is a man. But while he openly declares religion to be "strange to common sense," the practical result at which Charron arrives is that one is not to sit in judgment on his faith, but to be "simple and obedient," and to allow himself to be led by public authority. Another rule is to avoid superstition, which he defines as the belief that God is like a hard judge, and that therefore He must be flattered and importuned, and won over by pain and sacrifice. True piety is the knowledge of God and of one's self, the latter knowledge being necessary to the former. It leads to spiritual worship; for external ceremony is merely for our advantage, not for His glory. Charron is thus the founder of modern secularism. His political views are neither original nor independent. He pours scorn on the common herd, declares the sovereign to be the source of law, and asserts that popular freedom is dangerous.

A summary and defence of the *Sagesse* appeared in 1606. In 1607

Michel de la Rochemaillet prefixed to an edition of the *Sagesse* a Life. His complete works, with this Life, were published in 1635. An excellent abridgment of the *Sagesse* is given in Tennemann's *Philosophie*, vol. ix.; an edition with notes by A. Duval appeared in 1824.

See H. T. Buckle, *Intro. to History of Civilization in England*, vol. ii. p. 19 (1869); Abbé Lezat, *De la prédication sous Henri IV.* (1871); Liebscher, *Charron u. sein Werk, De la sagesse* (Leipzig, 1890); J. Owen, *Skeptics of the French Renaissance* (1893); W. E. H. Lecky, *Rationalism in Europe* (new ed. 1910); J. B. Sabrié, *De l'humanisme au rationalisme, Pierre Charron* (1913); J. M. Robertson, *A Short History of Free Thought*, vol. i. p. 480 (3rd. ed. 1915).

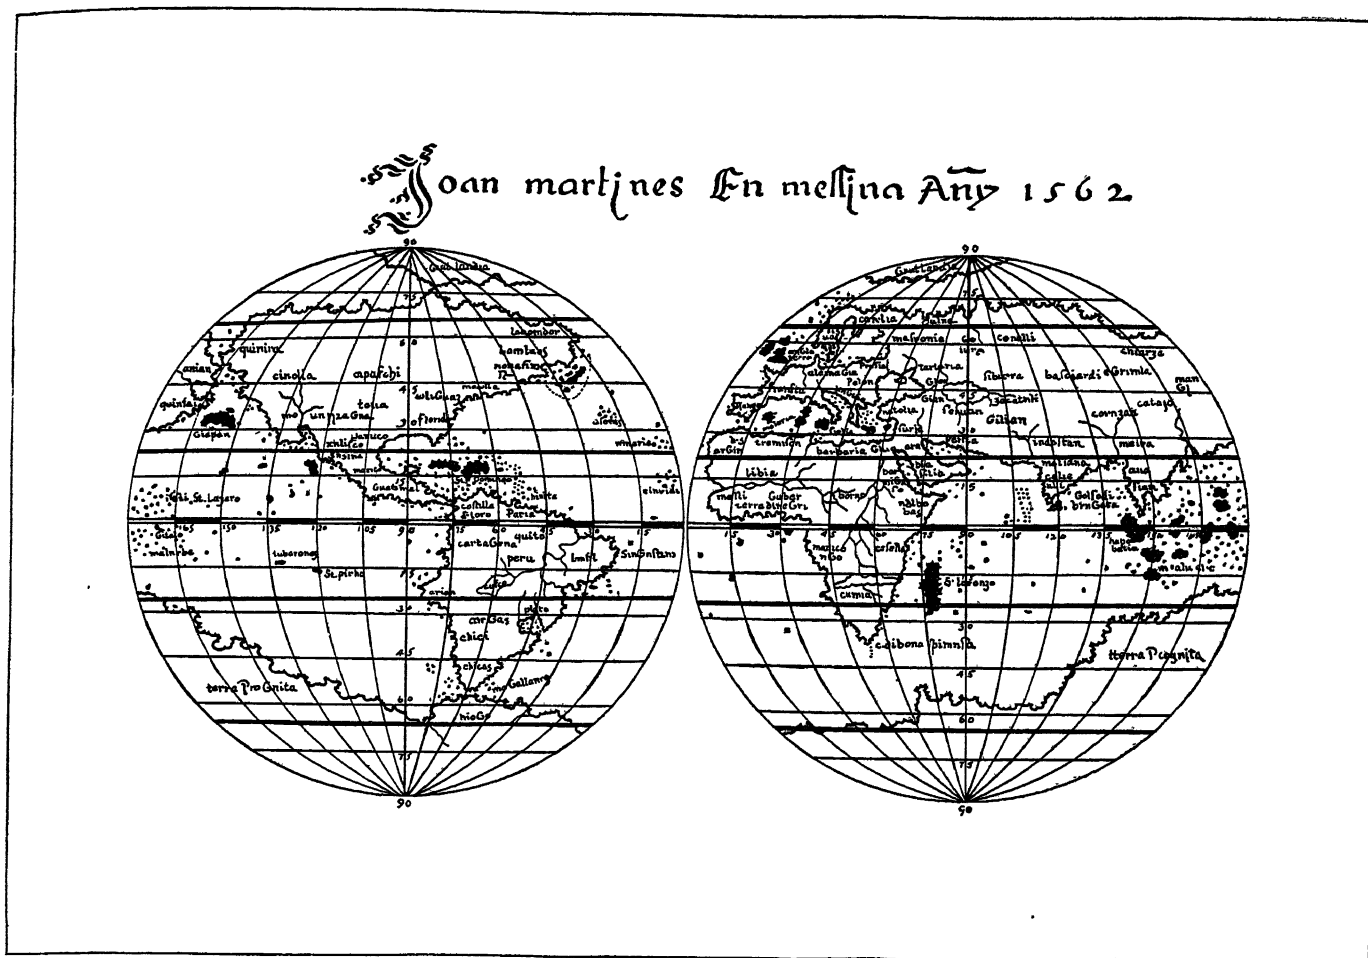

CHARRUA, an almost extinct tribe of South American Indians, wild and warlike, formerly ranging over Uruguay and part of southern Brazil. They were dark and heavily built, fought on horses and used the bolas or weighted lasso.

CHART. A chart is a marine map intended specially for the use of the seaman, to assist him to navigate seas and oceans, to sail from port to port and by its means to ascertain the position of a ship with reference to the land, the direction in which to steer, the distance to sail and the dangers to avoid. The water area on charts is studded with numerous small figures; these are the soundings, indicating in fathoms or in feet or in a combination of the two (as shown in the title of the chart) at mean low water spring tides the depth of water at any particular position. Charts show the nature of the sea bottom, the irregularity in its character and give information of the greatest importance to the mariner. No matter how well the land may be surveyed a chart is practically valueless unless soundings are shown.

The British admiralty charts are compiled, drawn and published by the hydrographic department. This department as established under Earl Spencer by an Order in Council in 1795 consisted of the hydrographer, one assistant and one draughtsman. The first hydrographer was Alexander Dalrymple, a gentleman in the East India Company's service; on his supersession in 1808 the office of hydrographer was filled by Captain Thomas Hurd, R.N., and has since been held by officers of the Royal Navy, amongst whom may be mentioned Admirals Sir Edward Parry, Sir Francis Beaufort and Sir William Wharton. At the present time, 1928, the department consists of the hydrographer, 15 naval assistants, 23 chief cartographers, and cartographers, 57 draughtsmen and 38 clerical staff, apart from the numerous engravers, printers, etc., who are employed in the final stages of preparing the work for publication.

Charts prepared by the hydrographic department and published by order of the Lords Commissioners of the Admiralty are compiled from the labours of British naval officers employed in the surveying service, also from surveys made by the Royal Australian Navy, Royal Indian Marine, South African Naval Service and contributions from officers of the Royal navy and mercantile marine. Generally speaking each maritime nation is considered to be responsible for the charting of its own coastal waters and those of its dependencies; the majority of these have efficient and well-organized hydrographic offices, carry out their own surveys and publish charts for the use of seamen. There is a free interchange of hydrographic information as between nations and foreign government charts are utilized and incorporated in various charts and publications produced by the British Admiralty, acknowledgment of the source of the information being made in the title of the chart. Admiralty charts, which are published with the view of meeting the wants of the seaman in all parts of the world, may be classed under five heads, viz., ocean, general, coastal, harbour and physical charts; they are constructed on either mercator or gnomonic projection according to scale and locality. After preparation at the hydrographic department they are engraved on copper plates which thereafter become the original printing medium and which are in constant correction due to the absolute necessity that the latest information should be available.

The depth of the sea is obtained by sounding line, wire or by sonic methods; all soundings are reduced to mean low water spring tides. The times and heights of the tides with the direction and the velocity of the tidal streams are also ascertained. The original surveys drawn by the surveyors afloat are forwarded to the Admiralty and form the basis of the published charts. The ocean and general charts are compiled and drawn at the hydrographic

BY COURTESY OF THE HISPANIC SOCIETY OF AMERICA

THE WORLD IN TWO HEMISPHERES, FROM THE ATLAS OF 7 CHARTS BY MARTINES OF MESSINA (1562), SHOWING THE EXTENT OF MARITIME DISCOVERY AT THAT DATE. THE AUSTRALIAN CONTINENT WAS STILL "TERRA INCOGNITA."

department; original documents, existing charts, latest surveys and maps have all to be consulted and their compilation requires experience and judgment, for the compiler has to decide what to omit, what to insert, and to arrange the necessary work in such a manner that full information is given to the seaman. A very slight error may lead to great disaster and every symbol on the chart must be delineated with great care. No pains are spared in the effort to lay before the public the labours of the hydrographic surveyors and explorers not only of England, but of all the maritime world, to reduce their various styles into a comprehensive system and to furnish the seaman with a guide of which he may take full advantage. Certain abbreviations are used on charts and are fully described in a special publication.

There are still enormous areas which are unsurveyed or not surveyed in sufficient detail for modern requirements. Charts of these localities are usually drawn in hairline so that the experienced seaman sees at a glance that caution is necessary. The charts issued to the public are correct at the time of publication and are kept corrected for newly reported dangers, changes in character or position of lights and buoys, recent publications of foreign governments, etc., this information being supplied gratis to the public in the Admiralty notices to mariners which are published weekly. Charts are supplemented by the "sailing directions" covering the whole of the navigable portion of the globe, tide tables, light lists, the Admiralty list of wireless time signals, the nautical almanac, distance tables, ocean passages of the world, in which is included information regarding winds and currents, etc.

NAUTICAL SURVEYING

Naval hydrographic surveying has since the termination of the war in 1918 steadily progressed in adopting the latest methods and instruments which have become available to the surveyor ashore

and afloat. It is not often realized that the hydrographic surveyor has to combine the work of the land surveyor with his own.

Instruments.—The following are the principal instruments required for use in the field and it should be noted that various scientific inventions of great benefit to the surveyor, and of which full advantage has already been taken, were designed and perfected during the World War, 1914–18.

Theodolites (*q.v.*) in current use (1928) are 4 in., 5 in. and 6 in. The majority of these are micrometer theodolites reading to 10 seconds. The use of the theodolite for astronomical and tachometer work is now universal.

Sextants for observing with stand and artificial horizon are still supplied and improvements in this instrument have been adopted; amalgamated troughs consisting of gold-covered plates on which a thin film of mercury is floated have superseded the old artificial horizon consisting of a mercury bath; the new pattern is far less sensitive to earth tremors. This instrument for work on shore is now to a great extent superseded by other more precise and compact instruments.

Astrolabe à prisme, a very precise instrument, is one of these. It is used for finding position and enables altitudes of any stars at the altitude of 45° or 60° to be observed. The latest form of astrolabe enables observations of stars to be easily and accurately made as follows with the 60° instrument—one step of 7½' on either side of 60°, that is 3 observations of 59° 52½', 60°, 60° 07½' can be taken of one star. With the 45° instrument—four steps of 5' on either side of 45°, that is 11 observations of 44° 35', 44° 40', 44° 45', 44° 50', 44° 55', 45°, 45° 05', 45° 10', 45° 15', 45° 20', 45° 25'—can be taken of one star. The great advantage of this instrument is that with one setting up of the instrument and without a number of necessary readjustments, as in a theodolite, both time and latitude can be determined, provided of

CERTAIN HYDROGRAPHIC INFORMATION ON THIS CHART IS REPRODUCED FROM BRITISH ADMIRALTY CHARTS WITH THE PERMISSION OF THE CONTROLLER OF H. M. STATIONERY OFFICE, AND OF THE HYDROGRAPHER OF THE NAVY, WHO ARE IN NO WAY RESPONSIBLE, HOWEVER, FOR THIS CHART

PORTION OF A CHART OF THE CHANNEL ISLANDS, SHOWING THE ISLAND OF ALDERNEY AND THE DANGEROUS ROCKS KNOWN AS THE CASQUETS. THE FIGURES GIVE SOUNDINGS IN FATHOMS

course that the best and latest method of obtaining error of the time used (i.e., wireless time signals) is adopted.

When it is found necessary to measure bases the hydrographic surveyor uses the 500 ft. steel measuring tape and is provided with the Kew standardization certificate. In surveying abroad where no local triangulation exists, the accurate measurement of a base is recognized as a most important step, second only to a satisfactory base extension. Tacheometers and tacheometer staves marked according to the Admiralty pattern are used for measuring distances up to over 2,000 ft. where extreme accuracy is not necessary. One-metre base range-finders are useful in measuring short bases for plans of harbours, etc., when time or circumstances do not permit of a more accurate method.

Sounding Sextants differ from ordinary sextants in being lighter and handier; the arc which is of brass is cut to minutes, reading to large angles of as much as 140° and fitted with a telescope of high power.

Station Pointer is in constant use for all kinds of plotting: it enables the observer's position to be fixed by two angles between three objects suitably placed, the centre of the instrument indicating the observer's position when set and applied to the plotting sheet.

Sun Signals for reflecting the rays of the sun to distance stations for the purpose of obtaining accurate angles and measurements. The most convenient form is Galton's Sun Signal, which is easy to operate, compact and portable.

In addition **pocket aneroid barometers** for topographical purposes, **prismatic compasses**, **patent logs**, **Lucas sounding machines**, both large and small, **James's submarine sentry**, **tacheometer staves**, etc., are also required. For chart room use **graduated brass scales**, **steel straight edges**, **beam compasses** of various lengths,

rectangular protractors, **circular brass protractors**, **mathematical drawing instruments**, **weights**, **drawing boards** and **paper** are required.

MARKS AND BEACONS

Every survey must have fixed objects which are first plotted on the sheets, technically known as "points." Natural marks of all kinds are utilized, but these must be supplemented by white-wash marks, cairns, flags, etc. On low coasts and islets flag staffs upwards of 100 ft. high made of several spars lashed together must sometimes be erected in order to get the necessary range of vision. A fixed beacon can be erected in shallow water by constructing a tripod of spars about 45 ft. long. The heads of two of them are lashed together and the heels kept open at a fixed distance by a plank nailed at about 5 ft. above the heels of the spars. These are taken out by three boats and the third tripod leg lashed in position on the boats, the heel in the opposite direction to the other two. The first two legs, weighted, are let go together; using the third leg as a prop, the tripod is hauled into position and secured by guys and by additional weights. A vertical pole with bamboo and flag, the heel being weighted, is lashed to the fork.

Floating Beacons.—These as a rule are specially constructed to carry a flag 12 to 16 ft. square on a bamboo from 30 to 35 ft. long. The beacon is secured to an anchor by means of chain or wire moorings and is visible under good conditions for a distance of about 10 miles. A beacon has been moored by sounding wire in depths of 3,000 fathoms with a weight of 100 lb.

Fixing.—In nautical surveying a thorough knowledge of the principles involved in a station-pointer fix is essential. The method of fixing by two angles between three fixed points is generally known as the "two-circle method," but there are really three circles involved. The "station-pointer" is the instrument used for

plotting fixes. Its construction depends upon the fact that angles subtended by the chord of a segment of a circle measured from any point in its circumference are equal. The lines joining three fixed points form the chords of segments of three circles, each of which passes through the observer's position and two of the fixed points. The more rectangular the angle at which the circles intersect each other, and the more sensitive they are, the better will be the fix; one condition is useless without the other. A circle is "sensitive" when the angle between the two objects responds readily to any small movement of the observer towards or away from the centre of the circle passing through the observer's position and the objects. This is most markedly the case when one object is very close to the observer and the other very distant, but not so when both objects are distant, but not so when both objects are distant. In the accompanying diagrams A, B, C are the objects, and X the observer. Fig. 1 shows the circle passing through C, B and X, cutting the circle ABX at a good angle, and therefore fixing X independently of the circle CAX, which is less sensitive, but being nearly tangential they give no cut with each other. The third cuts both at right angles; it is, however, far less sensitive, and for that reason if the right and left hand objects are both distant the fix must be bad. In such a case as this, because the angles CBX, BXA are both so sensitive, and the accuracy of the fix depends on the precision with which the angle CXA is measured, that angle should be observed direct, together with one of the other angles composing it. Fig. 3 represents a case where the points are badly disposed, approaching the condition known as "on the circle," passing through the three points. All three circles cut one another at such a fine angle as to give a very poor fix. The centre of the station-pointer could be moved considerably without materially affecting the coincidence of the legs with the three points. To avoid a bad fix the following rules are safe.

FIG. 1

Choose objects disposed as follows: (a) One outside object distant and the other two near, the angle between the two near objects being not less than 30° or more than 140° . The amount of the angle between the middle and distant object is immaterial. (b) The three objects nearly in a straight line, the angle between any two being not less than 30° . (c) The observer's position being inside the triangle formed by the objects. A fix on the line of two points in transit, with an angle to a third point, becomes more sensitive as the distance between the transit points increases relatively to the distance between the front transit point and the observer; the more nearly the angle to the third point approaches a right angle, and the nearer it is situated to the observer, the better the fix. If the third point is at a long distance, small errors either of observation or plotting will affect the result considerably.

FIG. 2

Tracing-paper answers exactly the same purpose as the station-pointer. The angles are laid off from a centre representing the position, and the lines brought to pass through the points as before. This has often to be used, as when points are close together on a small scale the central part of the station-pointer will often hide them and prevent the use of the instrument. The use of tracing-paper permits any number of angles to different points to be laid down on it, which under certain conditions of fixing is sometimes an advantage.

FIG. 3

Bases.—Marine surveys are founded upon triangulation and measured bases of some description, yet when plotted irregularly the system of triangles is not always apparent. The triangulation ranges from the rough triangle of a running survey to the carefully formed triangles of detailed surveys. The measured base for an extended survey is provisional only, the scale resting ultimately mainly upon the astronomical position observed as its extremes. In the case of a plan the base is absolute. The main triangulation establishes a series of points known as main stations, from which and to which angles are taken to fix other stations. A sufficiency of secondary stations enables the detail of the chart to be filled in between them. The points embracing the area to be worked on, having been plotted, are transferred to field boards, upon which the detail of the work in the field is plotted; when complete the work is traced and re-transferred to the plotting sheet, which is then inked in as the finished chart, and is graduated on the gnomonic projection on the astronomical positions of two points situated near opposite corners of the chart.

The kind of base ordinarily used is one measured by a steel tape of 100 or 500 ft. length on flat ground of convenient length, between two points visible from one another and so situated that a triangulation can be extended from them to embrace other points in the survey. The error of the steel tape is noted before leaving the ship, and again on returning, by comparing its length with a standard. The correction so found, also corrections for temperature, sag, etc., are applied to obtain the final result. A masthead angle base is at times useful for small plans, etc., when circumstances do not permit of a base being measured on shore. The height of the masthead to the water line being known the simple calculation necessary to obtain the distance is easily computed.

Astronomical Base.—The difference of latitude between two stations visible from each other and nearly in the same meridian, combined with their true bearings, gives an excellent base for an extended triangulation; the only drawback to it is the effect of local attraction of masses of land in the vicinity on the pendulum, or, in other words, on the mercury in the artificial horizon. The base stations should be as far apart as possible, in order to minimize the effect of any error in the astronomical observations. The observation spots would not necessarily be actually at the base stations, which would probably be situated on summits at some little distance in order to command distant views. In such cases each observation spot would be connected with its corresponding base station by a subsidiary triangulation, a short base being measured for the purpose. If possible, the observation spots should be east or west of the mountain station from which the true bearings are observed.

If the base stations A and B are so situated that by reason of distance or of high land intervening they are invisible from one another, but both visible from some main station C between them, when the main triangulation is completed, the ratio of the sides AC, BC can be determined. From this ratio and the observed angle ACB, the angles ABC, BAC can be found. The true bearing of the lines AC or BC being known, the true bearing of the base stations A and B can be deduced.

Extension of Base.—A base of any description is seldom long enough to plot from directly, and in order to diminish errors of plotting it is necessary to begin on the longest side possible so as to work inwards. A short base measured on flat ground will give a better result than a longer one measured over inequalities, provided that the triangulation is carefully extended by means of judiciously selected triangles, great care being taken to plumb the centre of each station. To facilitate the extension of the base in as few triangles as possible, the base should be placed so that there are two stations, one on each side of it, subtending angles at them of from 30° to 40° , the distances between which, on being calculated in the triangles of the quadrilateral so formed, will constitute the first extension of the base. Similarly, two other stations placed one on each side of the last two will form another quadrilateral, giving a yet longer side, and so on.

Main Triangulation.—The angles to be used in the main triangulation scheme must be very carefully observed and the theodolite placed exactly over the centre of the station. Main

angles are usually repeated several times by resetting the vernier at intervals equidistant along the arc, in order to eliminate instrumental errors as well as errors of observation. The selection of an object suitable for a zero is important. It should, if possible, be another main station at some distance, but not so far or so high as to be easily obscured, well defined, and likely to be permanent. Angles to secondary stations should be repeated. Rough sketches from all stations with angles are of great assistance in identifying objects from different points of view.

False Station.—When the theodolite cannot for any reason be placed over the centre of a station, if the distance be measured and the theodolite reading of it be noted, the observed angles may be reduced to what they would be at the centre of the station. False stations have frequently to be made in practice; a simple rule to meet all cases is of great assistance to avoid the possibility of error in applying the correction with its proper sign. It may very easily be found as follows.

Rule.—Put down the theodolite reading which it is required to correct (increased if necessary by 360°), and from it subtract the theodolite reading of the centre of the station. Call this remainder θ . With θ as a "course" and the number of feet from the theodolite to the station as a "distance," enter the traverse table and take out the greater increment if θ lies between 45° and 135° , or between 225° and 315° , and the lesser increment for other angles. The accompanying diagram (fig. 4) will assist the memory. Refer this increment to the "table of subtended angles by various lengths at different distances" (using the distance of the object observed) and find the corresponding correction in arc, which mark $+$ or $-$ according as θ is under or over 180° . Apply this correction to the observed theodolite angle. A "table of subtended angles" is unnecessary if the formula

FIG. 4

$$\text{Angle in seconds} = \frac{\text{Number of feet subtended} \times 34}{\text{Distance of object in sea miles}}$$

be used instead.

The difference of the reciprocal true bearings between two stations is called the "convergency." The formula for calculating it is: Conv. in minutes = dist. in sea miles \times sin. Merc. bearing \times tan. mid. lat. Whenever true bearings are used in triangulation, the effect of convergency must be considered and applied. In north latitudes the southerly bearing is the greater of the two, and in south latitudes the northerly bearing. The Mercatorial bearing between two stations is the mean of their reciprocal true bearings.

Triangulated Coast Survey.—After a preliminary run over the ground to note suitable positions for stations on prominent headlands, islands and summits not too far back from the coast, and, if no former survey exists, to make at the same time a rough plot of them by compass and patent log, a scheme must be formed for the main triangulation with the object of enclosing the whole survey in as few triangles as possible, regard being paid to the limit of vision of each station due to its height, to the existing meteorological conditions, to the limitations imposed by higher land intervening, and to its accessibility. The triangles decided upon should be well-conditioned, taking care not to introduce an angle of less than 30° to 35° , which is only permissible when the two longer sides of such a triangle are of nearly equal length, and when the determination of this length does not depend on the short side. In open country the selection of stations is a comparatively easy matter, but in country densely wooded the time occupied by a triangulation is largely governed by the judicious selection of stations quickly reached, sufficiently elevated to command distant views, and situated on summits capable of being readily cleared of trees in the required directions, an all-round view being, of course, desirable though not always attainable. The

positions of secondary stations will also generally be decided upon during the preliminary reconnaissance. The object of these stations is to break up the large primary triangles into triangles of smaller size, dividing up the distances between the primary stations into suitable lengths; they are selected with a view to greater accessibility than the latter, and should therefore usually be near the coast and at no great elevation. Upon angles from these will depend the position of the coastline marks, to be erected and fixed as the detailed survey of each section of the coast is taken in hand. The nature of the base to be used, and its position in order to fulfil the conditions specified under the head of *Bases* must be considered, the base when extended forming a side of one of the main triangles. It is immaterial at what part of the survey the base is situated, but if it is near one end, a satisfactory check on the accuracy of the triangulation is obtained by comparing the length of a side at the other extreme of the survey, derived by calculation through the whole system of triangles with its length deduced from a check base measured in its vicinity. It is generally a saving of time to measure the base at some anchorage or harbour that requires a large scale plan. The triangulation involved in extending the base to connect it with the main triangulation scheme can thus be utilized for both purposes, and while it is being calculated and plotted the survey of the plan can be proceeded with. The bearings are observed at both ends of the survey and at other selected stations and the results subsequently compared. Astronomical observations for latitude and longitude are obtained at observation spots near the extremes of the survey and are connected with the primary triangulation; they are usually disposed at intervals of from 100 to 150 m., and thus errors due to a triangulation carried out with theodolites of moderate diameter do not accumulate to any serious extent.

Calculating the Triangulation.—The triangles as observed being tabulated the angles of each triangle are corrected to bring their sum to exactly 180° . We must expect to find errors in the triangles, but under favourable conditions they will only amount to a few seconds. In distributing the errors we must consider the conditions under which the angles were observed; failing any particular reason to assign a larger error to one angle than to another, the error must be divided equally. The various quadrilaterals and polygons are then adjusted to make the whole triangulation as rigid as possible and bring the whole network into agreement. The length of base being determined, the sides of all the triangles involved are calculated by the ordinary rules of trigonometry. Starting from the true bearing observed at one end of the survey, the bearing of the side of each triangle that forms the immediate line of junction from one to the other is found by applying the angles necessary for the purpose in the respective triangles, not forgetting to apply the convergency between each pair of stations when reversing the bearings. The bearing of the final side is then compared with the bearing obtained by direct observation at that end of the survey. The difference is principally due to accumulated errors in the triangulation; half of the difference is then applied to the bearing of each side. Convert these true bearings into Mercatorial bearings by applying half the convergency between each pair of stations. With the lengths of the connecting sides found from the measured base and their Mercatorial bearing, the Mercatorial bearing of one observation spot from the other is found by middle latitude sailing. Taking the observed astronomical positions of the observation spots and first reducing their true difference longitude to departure, as measured on a spheroid from the formula

$$\text{Dep.} = \text{T.D. long.} \frac{\text{No. ft. in 1 m. of long.}}{\text{No. ft. in 1 m. of lat.}}$$

then with the d. lat. and dep. the Mercatorial true bearing and distance between the observation spots is calculated by middle latitude sailing, and compared with that by triangulation and measured base. To adjust any discrepancy, it is necessary to consider the probable error of the observation for latitude and meridian distance; within those limits the astronomical positions may safely be altered in order to harmonize the results; it is more important to bring the bearings into close agreement than the

distance. From the amended astronomical position the Mercatorial true bearings and distance between them are re-calculated. The difference between this Mercatorial bearing and that found from the triangulation and measured base must be applied to the bearing of each side to get the final corrected bearings, and to the logarithm of each side of the triangulation as originally calculated must be added or subtracted the difference between the logarithms of the distance of the amended positions of the observation spots and the same distance by triangulation.

Calculating Intermediate Astronomical Positions.—The latitude and longitude of any intermediate main station may now be calculated from the finally corrected Mercatorial true bearings and lengths of sides. The difference longitude so found is what it would be if measured on a true sphere, whereas we require it as measured on a spheroid, which is slightly less. The correction

$=d. \text{ long. } \frac{\cos^2 \text{ mid. lat.}}{150}$ must therefore be subtracted; or the true difference longitude may be found direct from the formula

$\text{Dep. } \frac{\text{No. ft. in 1 m. of lat.}}{\text{No. ft. in 1 m. of long.}}$. From the foregoing it is seen that

in a triangulation for hydrographical purposes both the bearings of the sides and their lengths ultimately depend almost entirely upon the astronomical observations at the extremes of the survey; the observed true bearings and measured base are consequently more in the nature of checks than anything else. It is obvious, therefore, that the nearer together the observation spots, the greater effect will a given error in the astronomical positions have upon the length and direction of the sides of the triangulation, and in such cases the bearings as actually observed must not be altered to any large extent when a trifling change in the astronomical positions might perhaps effect the required harmony. For the reasons given under *Astronomical Base*, high land near observation spots may cause very false results, which may often account for discrepancies when situated on opposite sides of a mountainous country.

Plotting.—Great care is requisite in projecting on paper the points of a survey. The paper should be allowed to stretch and shrink as it pleases until it comes to a stand, being exposed to the air for four or five hours daily, and finally well flattened out by being placed on a table with drawing boards placed over it heavily weighted. If the triangulation and co-ordinates have been calculated beforehand throughout, it is more advantageous to plot by co-ordinates or distances rather than by chords. The main stations are thus got down in less time and with less trouble, but these are only a small proportion of the points to be plotted, and if chords or distances are used long lines must be ruled between the stations as zeros for plotting other points by chords. In ruling these lines care must be taken to draw them exactly through the centre of the pricks denoting the stations, but, however, carefully drawn, there is liability to slight error in any line projected to a point lying beyond the distance of the stations between which the zero line is drawn. In plotting by distances, therefore, all points that will subsequently have to be plotted by chords should lie well within the area covered by the main triangulation. Three distances must be measured to obtain an intersection of the arcs cutting each other at a sufficiently broad angle; the plotting of the main stations once begun must be completed before distortion of the paper can occur from change in the humidity of the atmosphere. Plotting, whether by distance or by chords, must be begun on as long a side as possible, so as to plot inwards, or with decreasing distances. In plotting by chords it is important to remember in the selection of lines of reference (or zero lines), that that should be preferred which makes the smallest angle with the line to be projected from it, and of the angular points those nearest to the object to be projected from them.

Irregular Methods of Plotting.—In surveys for the ordinary purposes of navigation, it may happen that a regular system of triangulation cannot be carried out; the judicious use of the ship in such cases is often essential, and with proper care excellent results may be obtained. A few examples will best illustrate some

of the methods used, but circumstances vary in every survey. Fixing a position by means of the "back-angle" is one of the most ordinary expedients. Angles having been observed at A, to the station B, and certain other fixed points of the survey, C and D for instance; if A is shot up from B, at which station angles to the same fixed points have been observed, then it is not necessary to visit those points to fix A. For instance, in the triangle ABC, two of the angles have been observed, and therefore the third angle at C is known (the three angles of a triangle being equal to 180°), and it is called the "calculated or back-angle from C." A necessary condition is that the receiving angle at A, between any two lines (direct or calculated), must give a good cut; also the points from which the "back-angles" are calculated should not be situated at too great distances from A, relatively to the distance between A and B. A station may be plotted by laying down the line to it from one station, and then placing on tracing-paper a number of the angles taken at it, including the angle to the station from which it has been observed. If the points to which angles are taken are well situated, a good position is then obtained. Sometimes the main stations must be carried on with a point plotted by only two angles. An effort must be made to check this subsequently by getting an "angle back" from stations dependent upon it to some old well-fixed point; failing this, two stations being plotted with two angles, pricking one and laying down the line to the other will afford a check. A well-defined mountain peak, far inland and never visited, when once it is well fixed is often invaluable in carrying on an irregular triangulation, as it may remain visible when all other original points of the survey have disappeared, and "back-angles" from it may be continually obtained, or it may be used for plotting on true bearing lines of it. In plotting the true bearing of such a peak, the convergency must be found and applied to get the reversed bearing, which is then laid down from a meridian drawn through it; of the reversed bearing of any other line already drawn through the peak being known, it may simply be laid down with that as a zero.

FIG. 5.

A rough position of the spot from which the true bearing was taken must be assumed in order to calculate the convergency. Fig. 5 will illustrate the foregoing remarks. A and B are astronomical observation spots at the extremes of a survey, from both of which the high inaccessible peak C is visible. D, E, F are intermediate stations; A and D, D and E, E and F, F and B being respectively visible from each other. G is visible from A and D, and C is visible from all stations. The latitudes of A and B and meridian distance between them being determined, and the true bearing of C being observed from both observation spots, angles are observed at all the stations. Calculating the spheroidal correction from the formula, correction = d.

$\text{long. } \frac{\cos^2 \text{ mid. lat.}}{150}$ and adding it to the true (or chronometric)

d. long. between A and B to obtain the spherical d. long.; with this spherical d. long. and the d. lat., the Mercatorial true bearing and distance is found by middle latitude sailing (which is an equally correct but shorter method than by spherical trigonometry, and may be safely used when dealing with the distances usual between observation spots in nautical surveys). The convergency is also calculated, and the true bearing of A from B and B from A are thus determined. In the plane triangle ABC the angle A is the difference between the calculated bearing of B and the observed bearing of C from A. The distance AB having been calculated, the side AC is found. Laying down AC on the paper on the required scale, D is plotted on its direct shot from A, and on the angle back from C, calculated in the triangle ACD. G is plotted on the direct shots from A and D, and on the angle back from C, calculated either in the triangle ACG or GCD.

The perfect intersection of the three lines at G assures these four points being correct. E, F and B are plotted in a similar manner. The points depend on calculated angles, and except for the first four points we have no check, either on the accuracy of the angles observed in the field or on the plotting. Another well-defined object in such a position, for instance as Z, visible from three or more stations, would afford the necessary check, if lines laid off to it from as many stations as possible gave a good intersection. If no such point, however, exists a certain degree of check on the angles observed is derived by applying the sum of all the calculated angles at C to the true bearing of A from C (found by reversing observed bearing of C from A with convergency applied), which will give the bearing of B from C. Reverse this bearing with convergency applied, and compare it with the observed bearing of C from B. If the discrepancy is but small, it will be a strong presumption in favour of the substantial accuracy of the work. If the calculated true bearing of B from A be now laid down, it is very unlikely that the line will pass through B, but this is due to the discrepancy which must always be expected between astronomical positions and triangulation. If some of the stations between A and B require to be placed somewhat closely to one another, it may be desirable to obtain fresh true bearings of C instead of carrying on the original bearing by means of the calculated angle. In all cases of irregular plotting the ship is very useful, especially if she is moored taut without the swivel, and angles are observed from the bow. Floating beacons also assist an irregular triangulation.

Sketch Surveys.—Surveys of various degrees of accuracy are included among sketch surveys. The roughest description is the running survey, when the work is done by the ship steaming along the coast, fixing points, and sketching in the coast-line by bearings and angles, relying for her position upon her courses and distances as registered by patent log, necessarily regardless of the effect of wind and current and errors of steering. At the other extreme comes the modified running survey, which in point of practical accuracy falls little short of that attained by irregular triangulation. Some of these modifications will be briefly noticed. A running survey of a coast-line between two harbours, that have been surveyed independently and astronomically fixed, may often be carried out by fixing the ship on the points already laid down on the harbour surveys and shooting up prominent intermediate natural objects, assisted by theodolite angles. Theodolite lines to the ship and floating beacons suitably placed, materially increase the value of any such work. A sketch survey of a coast upon which it is impossible to land may be carried out by dropping beacons at intervals of about 8 m., well out from the land and placed abreast prominent natural objects called the "breastmarks," which must be capable of recognition from the beacons anchored off the next "breastmark" on either side. The distance between the beacons is found by running a patent log both ways, noting the time occupied by each run; if the current has remained constant, a tolerably good result can be obtained. At the first beacon, angles are observed between the second beacon and the two "breastmarks," and "intermediate" mark, and any other natural object which will serve as "points." At the second beacon, angles are observed between the first beacon and the same objects as before. Plotting on the line of the two beacons as a base, all the points observed can be pricked in on two shots. At a position about midway between the beacons, simultaneous angles are observed to all the points and laid off on tracing-paper, which will afford the necessary check, and the foundation is thus laid for filling in the detail of coast-line, topography, and soundings off this particular stretch of coast. Each section of coast is complete in itself on its own base; the weak point lies in the junction of the different sections, as the patent log bases will not agree precisely, and the scales of adjacent sections are liable to be slightly different. This is obviated, as far as possible, by fixing on the points of one section and shooting up those of another, which will check any great irregularity of scale creeping in. The bearing is preserved by getting occasional true bearing lines at the beacons of the most distant point visible. In all cases of using angles from the ship under weigh, several assistants are necessary, so that the principal

angles may be taken simultaneously, the remainder being connected immediately afterwards with zeros involving the smallest possible error due to the ship not being absolutely stationary, these zeros being included amongst the primary angles. When close to a beacon, if its bearing is noted and the distance in feet obtained from its elevation, the angles are readily reduced to the beacon itself. Astronomical positions by twilight stars keep a check upon the work.

Sketch Surveys by Compass Bearings and Vertical Angles.—In the case of an island culminating in a high, well-defined summit visible from all directions, a useful and accurate method is to steam round it at a sufficient distance to obtain a true horizon, stopping to make as many stations as may be desirable, and fixing by compass bearing of the summit and its vertical angle. The height is roughly obtained by shooting in the summit, from two positions on a patent log whilst approaching it. With this approximate height and Lecky's vertical danger angle tables, each station may be plotted on its bearing of the summit. From these stations the island is shot in by angles between its tangents and the summit, and angles to any other natural features, plotting the work as we go on any convenient scale which must be considered only as provisional. On completing the circuit of the island, the true scale is found by measuring the total distance in inches on the plotting sheet from the first to the last station, and dividing it by the distance in miles between them as shown by patent log. The final height of the summit bears to the rough height used in plotting the direct proportion of the provisional scale to the true scale. This method may be utilized for the sketch survey of a coast where there are well-defined peaks of sufficient height at convenient intervals, and would be superior to an ordinary running survey. From positions of the ship fixed by bearings and elevation of one peak, another farther along the coast is shot in and its height determined; this second peak is then used in its turn to fix a third, and so on. Lecky's tables will show what effect an error of say 1' in altitude will produce for any given height and distance, and the limits of distance must depend upon this consideration.

Surveys of Banks out of Sight of Land.—On striking shoal soundings unexpectedly, the ship may either be anchored at once and the shoal sounded by boats starring round her, using compass and masthead angle; or if the shoal is of large extent and may be prudently crossed in the ship, it is a good plan to get two beacons laid down on a bearing from one another and patent log distance of 4 or 5 m. With another beacon (or mark-boat, carrying a large black flag on a bamboo 30 ft. high) fixed on this base, forming an equilateral triangle, and the ship anchored as a fourth point, soundings may be carried out by the boats fixing by station-pointer. The ship's position is determined by observations of twilight stars.

Coastlining.—In a detailed survey the coast is sketched in by walking along it, fixing and plotting at intervals. Fixed marks along the shore afford a check on the minor coast-line fixes. When impracticable to fix in the ordinary way subtense methods are used. Greater accuracy is obtained if the work is plotted on the field board at once; this is not always possible but the angles being registered and sketches made of the intervening coast the work may be plotted afterwards. It is with the high water line that the coast-liner is chiefly concerned, delineating its character according to the accepted symbols. The sounder is responsible for the position of the dry line at low water. Heights of cliffs, rocks, islets, etc., must be inserted either from measurement or from the formula,

$$\text{Height in feet} = \frac{\text{Angle of elevation in seconds} \times \text{distance in miles}}{34}$$

and details of topography near the coast, including roads, houses and enclosures must be shown. Rocks above water or on which the sea breaks should be fixed. Coast-line may be sketched from a boat off shore by fixing and shooting up natural objects from selected positions.

Soundings.—The most important feature of a chart is the sounding, and the more complete this is the better is the survey.

Small scale surveys are apt to be misleading; such a survey may appear closely sounded but in reality it sometimes fails to disclose indications of shoal water. Sounding may be commenced as soon as sufficient points are plotted; but off an intricate coast it is better to get the coast-line in first. Lines of soundings are run by the boats perpendicular to the coast, at a distance apart governed by the scale; five lines to the inch is about as close as can be run without overcrowding. The distance apart will vary with the depth of water and the nature of the coast; for instance a rocky coast with shallow water off it will need closer examination than a steep coast. The prolongation of a point under water will require special care to ensure the fathom lines being correct. When soundings begin to decrease to seaward intermediate lines or lines crossing those previously run should be obtained. If possible lines of soundings should be run on transits; these may generally be picked up by fixing when on the required line, noting the angle on the protractor between the line and some fixed mark on the field board, then placing the angle on the sextant and noting what objects intersect at that angle. On large scale surveys it may be necessary to place transit marks in the required positions. The boat is fixed by two angles, with an occasional third angle as a check; the distance between the fixes is dependent upon the scale of the chart and the rapidity with which the depth alters; the 3, 6 and 10 fathom lines should always be fixed, allowing roughly for the tidal reduction. The nature of the bottom must be taken every few casts and recorded. It is best to plot each fix on the sounding board at once, joining the fixes by straight lines and numbering them for identification. The tidal reduction being obtained, the reduced soundings corrected for any lead line error are written in the field-book in red underneath each sounding as originally noted; they are then placed in their proper position on the board between the fixes. Suspicious ground should be closely examined; a small buoy anchored on the shoal is useful to guide the boat while trying for the least depth. Sweeping for a reported pinnacle rock should be resorted to when sounding fails to discover it. Local information from fishermen and others is often of value. Up to depths of about 15 fathoms the hand lead-line is used from the boats, but beyond that depth the Lucas machine for wire effects a great saving of time and labour. The deeper soundings of a survey are usually obtained from the ship, but steamboats with wire sounding machines often assist very materially. By the aid of a steam winch, a 100-lb. lead is hove forward to the end of the lower boom rigged out, from which it is dropped by reversing the winch, soundings of 50 fathoms may be picked up from the sounding platform aft, whilst going at a speed of 5 to 6 knots. In deeper water it is quicker to stop the ship and sound from aft with the wire sounding machine. In running lines of soundings on and off shore, it is essential to be able to fix as far from the land as possible. Angles will be taken from aloft for this purpose, and floating beacons dropped in selected positions will be of assistance. A single fixed point on the land used in conjunction with two beacons suitably placed will give an admirable fix.

Echo Sounding.—This method of obtaining the depth is likely to prove of increasing value as time goes on and its efficiency becomes known. The principle is that an electric impulse is transmitted from the bottom of a ship, strikes the bed of the ocean and is reflected as an echo which is received by a hydrophone. The sound waves are sent out at fixed intervals and the echo is heard in telephone receivers connected with the hydrophone. The velocity of sound in water being known the depth can be calculated provided the time interval is accurately measured. A hand wheel, working a depth scale and connected with the telephonic gear is manipulated until echoes are heard in the receiver; the depth can then be read off the circular scale.

The Admiralty echo sounding apparatus shallow water type is designed to register depths of from 3 to 120 fathoms; for greater depths a modified form of echo gear is utilized. The saving of time is particularly noticeable where great depths are being obtained, the echo gear giving a result in a few seconds, whereas with a wire sounding machine the operation is a lengthy proceeding often occupying more than an hour. The disadvantage of echo

sounding is that it is impossible to determine the nature of the bottom by this means and where a survey is in progress this must be obtained with the lead.

Vigias.¹—A certain percentage of *vigias* which are reported and placed on the charts eventually turn out to have no existence, but before it is possible to expunge them the area has to be examined. Submarine banks rising from great depths necessarily stand on bases many square miles in area. Of recent years our knowledge of the angle of slope that may be expected to occur at different depths has been much extended. From depths upwards of 2,000 fathoms the slope is so gradual that a bank could hardly approach the surface in less than 7 m. from such a sounding; therefore anywhere within an area of at least 150 sq.m. all round a bank rising from these depths, a sounding must show some decided indications of a rise in the bottom. Under such circumstances, soundings at intervals of 7 m., and run in parallel lines 7 m. apart, enclosing areas of only 50 sq.m. between any four adjacent soundings, should clear up the ground and lead to the discovery of any shoal. As the depth decreases the angle of slope rapidly increases, and a shoal might occur within three-quarters of a mile or even half a mile of such a sounding as 500 fathoms. An appreciation of these facts will indicate the distance apart at which it is proper to obtain soundings. Contour lines will show in which direction to prosecute the search. When once a decided indication is found, it is not difficult to follow it up by paying attention to the contour lines as developed by successive soundings. Discoloured water, ripples, fish jumping or birds hovering about may assist in locating a shoal, but the submarine sentry towed at a depth of 40 fathoms is here most valuable, and may save hours of hunting. Reports being more liable to errors of longitude than of latitude, a greater margin is necessary in that direction. Long parallel lines east and west are preferable, but the necessity of turning the ship more or less head to wind at every sounding makes it desirable to run the lines with the wind abeam, which tends to disturb the dead reckoning least. The current should be allowed for in shaping the course to preserve the parallelism of the lines, but the less frequently the course is altered the better. A good position should be obtained at morning and evening twilight by pairs of stars on opposite bearings, the lines of position of one pair cutting those of another pair nearly at right angles. The dead reckoning should be checked by lines of position from observations of the sun about every two hours throughout the day, preferably whilst a sounding is being obtained and the ship stationary.

Tides.—The datum for reduction of soundings is mean low-water springs, the level of which is referred to a permanent bench mark in order that future surveys may be reduced to the same datum level. Whilst sounding is going on the height of the water above this level is observed by a tide gauge. The time of high-water at full and change, called the "establishment," and the heights to which spring and neap tides respectively rise above the datum are also required. It is seldom that a sufficiently long series of observations can be obtained for their discussion by harmonic analysis, and therefore the graphical method is preferred. A good portable automatic tide gauge suitable for all requirements is much to be desired.

Tidal streams and surface currents are observed from the ship or boats at anchor by means of a current log. An alternative method is to follow a drifting buoy fixing the position at intervals. Tidal streams often run for some hours after high or low water by the shore; it is important to determine whether the change of stream occurs at a regular time of the tide.

Undercurrents are also of importance. A deep-sea current meter devised (1876) by Lieutenant Pillsbury, U.S.N., has been used with success on many occasions, notably in the investigation of the Gulf Stream. More recent developments of deep-sea current meters are the Ekman, Jacobsen, Sverdrup, Woolaston and Caruthers instruments. The instrument is lowered to the required depth and brought into action by a messenger, travelling down the supporting line and operating a lever which sets the instrument

¹Spanish word meaning "look-out," used of marks on the chart signifying obstruction to navigation.

free, or some similar contrivance. On the completion of the necessary interval the meter is locked whilst still below the surface, hauled up and examined. The time during which the instrument has been working at the required depth is known and the direction and strength of the current can be determined from the mechanical arrangements.

Topography.—Generally speaking the topographical features should be delineated as far back as the skyline viewed from seaward, in order to assist the navigator to recognize the land. Summits of hills, conspicuous spurs, cliffs, etc., are fixed and their heights determined by theodolite elevations or depressions to and from positions where the height above the water is known. The shape is delineated by contour lines sketched by eye, assisted by an aneroid barometer. In wooded country much of the topography may have to be determined from the ship; sketches from different positions at anchor with the necessary angles to fix the features give a fair idea of the general lie of the country.

Latitudes.—Circum-meridian altitudes of stars observed by sextant in the artificial horizon is one of the methods adopted for observations for latitudes. Arranged in pairs of nearly the same altitude north and south of zenith, the mean of each pair give a result from which instrumental and personal errors and errors due to atmospheric conditions are eliminated. The mean of several such pairs should have a probable error of not more than $\pm 1''$. The observations of each star should be confined to within 5 or 6 minutes on either side of the meridian. Two stars selected to "pair" should pass the meridian within an hour of each other, and should not differ in altitude more than 2° or 3° . Artificial horizon error is eliminated by always keeping the same end of the roof towards the observer; when observing a single object, as the sun, the roof must be reversed when half way through the observations. The observations are reduced to the meridian by Raper's method. When pairs of stars are not observed, circum-meridian altitudes of the sun may be resorted to, but being observed on one side of the zenith only, none of the errors to which all observations are liable can be eliminated.

Chronometer Errors.—Equal altitudes of sun or stars by sextant and artificial horizon are employed to obtain chronometer errors. Six sets of eleven observations, A.M. and P.M., observing both limbs of the sun, should give a result which, under favourable conditions of latitude and declination, may be expected to vary less than two-tenths of a second from the normal personal equation of the observer. Stars give equally good results. In high latitudes sextant observations diminish in value owing to the slower movement in altitude. In the case of the sun all the chronometers are compared with the "standard" at apparent noon; the comparisons with the chronometer used for the observations on each occasion of landing and returning to the ship are worked up to noon. In the case of stars, the chronometer comparisons on leaving and again on returning are worked up to an intermediate time. A convenient system, which retains the advantage of the equal altitude method, whilst avoiding the necessity of waiting some hours for the P.M. observation, is to observe two stars at equal altitudes on opposite sides of the meridian, and, combining the observations, treat them as relating to an imaginary star having the mean right ascension and mean declination of the two stars selected, which should have nearly the same declination and should differ from 4^h to 8^h in R.A.

Meridian Distances.—The error of chronometer on mean time of place being obtained, the local time is transferred from one observation spot to another by the ship carrying usually eight box chronometers. The best results are found by using travelling rates, which are deduced from the difference of the errors found on leaving an observation spot and returning to it; from this difference is eliminated that portion which may have accumulated during an interval between two determinations of error at the other, or any intermediate, observation spot. A travelling rate may also be obtained from observations at two places, the meridian distance between which is known; this rate may then be used for the meridian distance between places observed during the passage. Failing travelling rates, the mean of the harbour rates at either end must be used. The same observer, using the same instrument,

must be employed throughout the observations of a meridian distance.

If the telegraph is available, it should be used. The error on local time at each end of the wire is obtained, and a number of telegraphic signals are exchanged between the observers, an equal number being transmitted and received at either end. The local time of sending a signal from one place being known and the local time of its reception being noted, the difference is the meridian distance. The retardation due to the time occupied by the current in travelling along the wire is eliminated by sending signals in both directions. The relative personal equation of the observers at either end, both in their observations for time, and also in receiving and transmitting signals, is eliminated by changing ends and repeating the operations. If this is impracticable, the personal equations should be determined and applied to the results. Chronometers keeping solar time at one end of the wire, and sidereal time at the other end, materially increase the accuracy with which signals can be exchanged, for the same reason that comparisons between sidereal clocks at an observatory are made through the medium of a solar clock. Time by means of the sextant can be so readily obtained, and within such small limits of error, by skilled observers, that in hydrographic surveys it is often employed; but if transit instruments are available, and sufficient time can be devoted to erecting them properly, the value of the work is greatly enhanced.

True Bearings are obtained on shore by observing with theodolite the horizontal angle between the object selected as the zero and the sun, taking the latter in each quadrant as defined by the cross-wires of the telescope. The altitude may be read on the vertical arc of the theodolite; except in high latitudes, where a second observer with sextant and artificial horizon are necessary, unless the precise errors of the chronometers are known, when the time can be obtained by carrying a pocket chronometer to the station. The sun should be near the prime vertical and at a low altitude; the theodolite must be very carefully levelled, especially in the position with the telescope pointing towards the sun. To eliminate instrumental errors the observations should be repeated with vernier set at intervals equidistant along the arc, and A.M. and P.M. observations should be taken at about equal altitudes.

At sea true bearings are obtained by measuring with a sextant the angle between the sun and some distant well-defined object making an angle of from 100° to 120° and observing the altitude of the sun at the same time, together with that of the terrestrial object. The sun's altitude should be low to get the best results, and both limbs should be observed. The sun's true bearing is calculated from its altitude, the latitude and its declination; the horizontal angle is applied to obtain the true bearing of the zero. On shore the theodolite gives the horizontal angle direct, but with sextant observations it must be deduced from the angular distance and the elevation.

CHARTER, a written instrument, contract, or convention by which grants of property or of rights and privileges are confirmed and held. The use of the word for any written document is obsolete in England, but is preserved in France, e.g., the *École des Chartes* at Paris. In feudal times charters of privileges were granted, not only by the Crown, but by mesne lords both lay and ecclesiastical, as well to communities, such as boroughs, gilds and religious foundations, as to individuals. In modern usage grants by charter have become all but obsolete, though in England this form is still used in the incorporation by the Crown of certain public bodies (*see* CHARTERED COMPANIES).

The grant of the Great Charter by King John in 1215 (*see* MAGNA CARTA), which guaranteed the preservation of English liberties, led to a special association of the word with constitutional privileges, and so in modern times it has been applied to constitutions granted by sovereigns to their subjects, in contradistinction to those based on "the will of the people." Such was

the Charter (*Charte*) granted by Louis XVIII. to France in 1814. In Portugal the constitution granted by Dom Pedro in 1826 was called by the French party the "Charter," while that devised by the Cortes in 1821 was known as the "Constitution." Magna Carta also suggested to the English radicals in 1838 the name "People's Charter," which they gave to their published programme of reforms (*see* CHARTISM). This association of the idea of liberty with the word charter led to its figurative use in the sense of freedom or licence. The common colloquialism "to charter," in the sense of to take, or hire, is derived from the special use of "to charter" as to hire (a ship) by charter-party.

CHARTERED ACCOUNTANT: *see* ACCOUNTANCY AND ACCOUNTANTS.

CHARTERED COMPANIES. A chartered company is a corporation enjoying certain rights and privileges, and bound by certain obligations under a special charter granted to it by the sovereign authority of the State, such charter defining and limiting those rights, privileges and obligations, and the localities in which they are to be exercised. Such companies existed in early times, but have undergone changes and modifications in accordance with the developments which have taken place in the economic history of the States where they have existed. In Great Britain the first charters for foreign trade were granted, not to English companies but to branches of the Hanseatic League (*q.v.*), and it was not till 1598 that England was finally relieved from the presence of a foreign chartered company. In that year Queen Elizabeth closed the steel-yard where Teutons had been established for 700 years.

Of all early English chartered companies, the "Merchant Adventurers" conducted its operations the most widely. Itself a development of very early trading guilds, at the height of its prosperity it employed as many as 50,000 persons in the Netherlands. In the reign of Elizabeth British trade with the Netherlands, reached, in one year, 12,000,000 ducats, and in that of James I. the company's yearly commerce with Germany and the Netherlands was as much as £1,000,000. Hamburg afterwards was its principal depot, and it became known as the "Hamburg company." Here it maintained itself until as late as 1808, when the company was at last dissolved. In the "Merchant Adventurers" enterprises is to be seen the germ of the trading companies which had so remarkable a development in the 16th and 17th centuries. These old regulated trade guilds passed gradually into joint-stock associations, which were capable of far greater extension in both the number of members and the amount of stock, each member being only accountable for the amount of his own stock, and being able to transfer it at will to any other person.

The discovery of the New World, and the opening out of fresh trading routes to the Indies, gave an extraordinary impulse to shipping, commerce and industrial enterprise throughout western Europe. The English, French and Dutch Governments were ready to assist trade by the granting of charters to trading associations. The Baltic trade had already been the sphere of activities of an English company, since Henry IV. founded one by charter in 1404; and Elizabeth revived this "Eastland company" in 1579. To the "Russia company," which received its first charter in 1553, Great Britain owed its first intercourse with Russia and a direct trade with the Levant and Persia. Later, the Turkey company was founded, which in 1592, after amalgamation with the Venice company, took the name of the Levant company. Like the Muscovy company it was still trading in the 18th century. Both the Russia and Turkey companies had an important effect upon British relations with those empires. They maintained British influence in those countries, and even paid the expenses of the embassies which were sent out by the English Government to their courts.

The chartered companies which were formed during this period for trade with the Indies and the New World have had a more wide-reaching influence in history. The East India company (*q.v.*) is dealt with elsewhere. Charters were given to companies trading to Guiana and the Canaries, but none of these enjoyed a very long or prosperous existence, principally owing to the difficulties caused by foreign competition. It is when we turn to North America that the importance of the chartered company, as

a colonizing rather than a trading agency, is seen in its full development. The "Hudson's Bay company," which still exists as a commercial concern, is dealt with under its own heading, but many of the 13 British North American colonies were in their inception chartered companies very much in the modern acceptance of the term. The history of these companies will be found under the heading of the different colonies of which they were the origin. It is necessary, however, to bear in mind that two classes of charters are to be found in force among the early American colonies: (1) Those granted to private individuals or to trading associations, which were often useful when the colony was first founded, but which were later withdrawn when the country had become settled and was looking forward to commercial expansion. The colonies were then brought under the direct control of the Crown, and their trade subject only to regulation by the Government. Thus the Virginia company lost their charter in 1624. The substitution of royal and later of parliamentary control for that of the company was an important factor in the growth of the Navigation Acts. (2) The second class of charters were those granted to the settlers themselves as a guarantee of their system of government. This, for example, was the effect of the charter granted to Massachusetts. In the later 17th century, however, the cancellation or amendment of the charters, and the growth of legislative assemblies tended to produce a uniformity of colonial practice, irrespective of the original character of the colony.

Chartered companies continued to be formed for the development of new trade, *e.g.*, the Royal African company in 1662 and the South Sea company in 1711.

In France and Holland, no less than in England, the institution of chartered companies became a settled principle of the Governments of those countries during the whole of the period in question. In France from 1599 to 1789, more than 70 of such companies came into existence, but after 1770, when the great *Compagnie des Indes orientales* went into liquidation, they were almost abandoned, and finally perished in the general sweeping away of privileges which followed on the outbreak of the Revolution. The monopoly rights granted to such companies were in accordance with the views generally accepted at the time, although there were many critics even in the 17th century. There were serious difficulties in the way of private trade owing to the large capital required to maintain factories and the necessity for their supervision. It was only the need for capital which induced statesmen like Colbert to countenance them, and Montesquieu took the same view (*Esprit des lois*, t. xx.c. 10). John de Witt's view was that such companies were not useful for colonization properly so called, because they wanted quick returns to pay their dividends. So, even in France and Holland, opinion was by no means settled as to their utility. In England historic protests were made against such monopolies, but the chartered companies were less exclusive in England than in either France or Holland. French commercial companies were more privileged, exclusive and artificial than those in Holland and England. Those of Holland may be said to have been national enterprises. French companies were more fettered than their rivals by the royal power and had less initiative of their own, and therefore had less chance of surviving.

During the last 20 years of the 19th century there was a great revival of the system of chartered companies in Great Britain. It was a feature of the general growth of interest in colonial expansion and commercial development which had made itself felt almost universally among European nations. But the modern companies were not like those of the 16th and 17th centuries; they were not monopolists, and were more definitely subject to the control of the Home Government. The charters, in fact, prohibited any monopoly of trade, and prescribed a State control which is their distinguishing feature. It is to be exercised in almost all directions in which the companies may come into contact with matters political; it is inevitable in all disputes of the companies with foreign Powers and is extended over all decrees of the company regarding the administration of its territories, the treatment of natives and mining regulations. In all

cases of dispute between the companies and the natives the secretary of State is *ex officio* the judge, and to the secretary of State (in the case of the British South Africa company) the accounts of administration had to be submitted for approbation. The British character of the company is insisted upon in each case in the charter which calls it into life. The Crown always retains complete control over the company by reserving to itself the power of revoking the charter in case of the neglect of the stipulations. Special clauses were inserted in the charters of the British East Africa and South Africa companies enabling the Government to forfeit their charters if they did not promote the objects alleged as reasons for demanding a charter.

The chartered company of these days is therefore very strongly fixed within limits imposed by law on its political action. As a whole, however, very remarkable results have been achieved. This may be attributed in no small degree to the personality of the men who have had the supreme direction at home and abroad, and who have, by their social position and personal qualities, acquired the confidence of the public. With the exception of the Royal Niger company, it would be incorrect to say that they have been financially successful, but in the domain of Government generally it may be said that they have added vast territories to the British empire (in Africa about 1,700,000 sq.m.), and in these territories they have acted as a civilizing force. They have made roads, opened facilities for trade, enforced peace and laid, at all events, the foundation of settled administration; while anti-slavery and anti-alcohol campaigns have been carried on, the latter certainly being against the immediate pecuniary interests of the companies themselves. The occupation of Uganda certainly, and of the Nigerian territory and Rhodesia probably, will prove to have been rather for the benefit of posterity than of the companies which effected it. In the two cases where the companies have been bought out by the State, they have had no compensation for much that they have expended.

One common characteristic is to be noted in the histories of the old chartered companies and the new. In both periods the company has been used by the English Government as a useful instrument of colonial expansion, but in both periods only for temporary uses. When the colony is settled, or Government established, the State takes the lead. This is well illustrated by the history of the slow decline of the independence of the East India company in the 18th century and of the British South Africa company in the 20th. Both these companies are distinguished for their length of days, but both had to submit to the gradual penetration of State control.

See also BORNEO, NIGERIA, RHODESIA, etc. For the share of the chartered company in the development of the modern trading company, see COMPANY.

CHARTERHOUSE, a corruption of the French *maison chartreuse*, a religious house of the Carthusians (*q.v.*). The name is found in various places in England (e.g., Charterhouse-on-Mendip, Charterhouse Hinton) where the Carthusians were established, but is most familiarly applied to the Charterhouse, London. Near the old city wall, west of the modern thoroughfare of Aldersgate, a Carthusian monastery was founded in 1371 by Sir Walter de Manny. After its dissolution in 1535, the property was occupied

for a time by Queen Elizabeth (in 1558) and by James I. In May 1611 the Charterhouse came into the hands of Thomas Sutton (1532-1611) of Snaith, Lincolnshire. He acquired a fortune by the discovery of coal on two estates which he had leased near Newcastle-on-Tyne, and afterwards, removing to London, he carried on a commercial career. In 1611, the year of his death, he endowed a hospital on the site of the Charterhouse, calling it the hospital of King James and in his will he bequeathed money to maintain a chapel, hospital (almshouse) and school. The will was hotly contested but upheld in court, and the foundation was finally constituted to afford a home for 80 male pensioners and to educate 40 boys. The school developed beyond the original intentions of its founder, and now ranks as a public school. In 1872 it was removed to new buildings near Godalming in Surrey. The pensioners still occupy the picturesque buildings of mellowed red brick, which include a panelled chapel, in which is the founder's tomb, the fine dining-hall—rebuilt by the monks about 1520—the old library and the great staircase.

CHARTER-PARTY: see AFFREIGHTMENT.

CHARTERS TOWERS: see TOWNSVILLE.

CHARTIER, ALAIN (c. 1392-c. 1430), French poet and political writer, was born at Bayeux about 1392. His eldest brother, Guillaume, became bishop of Paris; and Thomas became notary to the king. Jean Chartier, a monk of St. Denis, whose history of Charles VII. is printed in vol. iii. of *Les Grands Chroniques de Saint-Denis* (1477), was not, as is sometimes stated, also a brother of the poet. Alain studied, as his elder brother had done, at the University of Paris. His earliest poem is the *Livre des quatre dames*, written after the battle of Agincourt. This was followed by the *Débat du réveille-matin*, *La Belle Dame sans merci* and others. He was attached to the dauphin, afterwards Charles VII., acting in the triple capacity of clerk, notary and financial secretary. In 1422 he wrote the famous *Quadriologue-invectif*. The interlocutors in this dialogue are France herself and the three orders of the State. Chartier lays bare the abuses of the feudal army and the sufferings of the peasants. He rendered an immense service to his country by maintaining that the cause of France, though desperate to all appearance, was not yet lost if the contending factions could lay aside their differences in the face of the common enemy. In 1424 Chartier was sent on an embassy to Germany, and three years later he accompanied to Scotland the mission sent to negotiate the marriage of Margaret of Scotland, then not four years old, with the dauphin, afterwards Louis XI. In 1429 he wrote the *Livre d'espérance*, which contains a fierce attack on the nobility and clergy. He was the author of a diatribe on the courtiers of Charles VII., entitled *Le Curial*, translated into English (*Here followeth the copy of a lettre whyche maistre A. Charetier wrote to his brother*) by Caxton about 1484. The story of the famous kiss bestowed by Margaret of Scotland on *la précieuse bouche de laquelle sont issus et sortis tant de bons mots et vertueuses paroles* is mythical, for Margaret did not come to France till 1436, after the poet's death. Jean de Masles, who annotated a portion of his verse, has recorded how the pages and young gentlemen of that epoch were required daily to learn by heart passages of his *Bréviaire des nobles*. John Lydgate studied him affectionately. *La Belle Dame sans merci* was translated into English by Sir Richard Ros about 1640, with an introduction of his own; and Clément Marot and Octavien de Saint-Gelais, writing 50 years after his death, find many fair words for the old poet, their master and predecessor.

See Mancel, *Alain Chartier, étude bibliographique et littéraire*, 8vo (1849); D. Delaunay's *Étude sur Alain Chartier* (1876), with considerable extracts from his writings, and G. Joret-Desclosières, *Alain Chartier* (4th ed., 1899). His works were edited by A. Duchesne (Paris, 1617).

CHARTISM, the name of a revolutionary democratic agitation in Great Britain which came into prominence in 1838 and disappeared after 1850.

The "People's Charter" was the name given to a bill containing the famous six points—equal electoral areas, universal suffrage, payment of members, no property qualifications, vote by ballot, and annual parliaments—all but the last of which have since been secured. These points, which from 1768 had been, partially at

least, the common property of all radical agitation, were first collected into one petition on Feb. 18 1837, by the London Workingmen's Association, founded by William Lovett, as a result of the great disappointment of the Reform Bill of 1832, which enfranchised only the middle class. These six points were drafted into a bill known as the Charter by Lovett, with possibly some assistance from Francis Place, which was published on May 8 1838; and the formal constitution of the Chartist movement is commonly dated from a great meeting held on Aug. 8 on Newhall Hill at which the Charter was approved.

The ultimate aims of the movement were economic—"social equality" or, in the phrase of G. J. Harney's *London Democrat*, (April 27 1839) "that all shall have a good house to live in with a garden back or front, just as the occupier likes; good clothing to keep him warm and to make him look respectable, and plenty of good food and drink to make him look and *feel* happy." The Chartists were not unanimous about the means of securing this social equality, but a provisional agreement on universal suffrage as the necessary first step provided the basis of the movement. The London Workingmen's Association, which launched the campaign by sending out "missionaries" all over Great Britain, consisted of skilled workers mostly above the poverty line: not so the supporters to whom they appealed. The factory workers, colliers and handloom workers of the North and Midlands, who became the chief adherents of Chartism, were passing through a period of extreme misery and degradation, which was not at this time mitigated by any effectively administered Factory Act (except one which limited, in some cases, the working hours of certain children to 12). Two Tory factory reformers, Richard Oastler and the Rev. J. R. Stephens, were, moreover, conducting, in an exceedingly violent manner, a campaign against the provisions of the Poor Law of 1834, which aimed at making poor relief more unpleasant than the most unpleasant means of gaining a livelihood outside. Oastler and Stephens, whose campaign in several areas succeeded in postponing its application, threw their weight into the Chartist movement, and over the whole of the Northern area torchlight meetings were held at night on the moors, in which armed insurrection was freely advocated. Scotland, and the west of England, which was evangelized by Henry Vincent, the most eloquent Chartist orator, were the moderate areas: the Welsh miners were the most revolutionary. Feargus O'Connor (*q.v.*), an Irish squire who had formerly (1832-35) been one of O'Connell's "tail" in Parliament, became rapidly the most popular leader, and rarely made a speech without alluding to physical force.

The new Chartist plan of campaign was, however, provided by a banker, Thos. Attwood, M.P. for Birmingham, who trusted that a Charter parliament would adopt his views on currency. He proposed the election, by the disfranchised, of an anti-Parliament to be called the Convention which would sit as a rival to the House of Commons and present a petition, signed by the mass of the working class, for the enactment of the Charter as the law of the land. If the Commons refused, the Convention would then call a general strike (the "Sacred Month"). This exhilarating programme was enthusiastically taken up; the petition was signed by 1,280,000 people and the members of the Convention, elected by public meetings, held their first sitting in London on Feb. 4 1839. The Convention was at the beginning controlled by the "moral force men" headed by Lovett, but it was not able to prevent frequent violent conflicts with the police (in which the Chartists were not uncommonly victorious) and the moderates entirely lost control when on July 12 the Commons, after long delays, rejected the petition. Post-dated orders for the General Strike were forthwith issued, amid great excitement. Only a few days had passed, however, when the Convention realized that it had behind it no organization and no preparations, and in consequence somewhat ignominiously cancelled the orders on July 22.

What the "moral force men" would not do, others were prepared to attempt. During the Convention a secret military organization had been formed, directed by a committee of five: its plans were completed at a private conference held in the autumn at Heckmondwike. The signal for the insurrection was to be given

by the capture of Newport (Mon.) and the release of Vincent from Monmouth Castle. The other centres of revolt appear to have been in Lancashire and Yorkshire. The attack on Newport was led by the ex-mayor and J.P., John Frost, on the morning of Nov. 4. It was to have been in three columns, but owing to mismanagement the columns failed to unite at Risca and Frost attacked alone with about 3,000 men armed with rifles and mandrills (collier's picks). Warning had been given and the Chartists walked into a trap in the square outside the Westgate hotel. They were defeated after a very brief struggle, leaving a considerable number (the figures are disputed) of killed and wounded. The leaders, Frost, Jones and Williams, were sentenced to death, afterwards mitigated to transportation. The police also rounded up nearly every other Chartist leader of importance, and secured sentences of one or two years' imprisonment.

On the release of the leaders in 1840 and 1841 renewed quarrels broke out between the "physical force men" led by O'Connor and his assistant on the *Northern Star*, G. J. Harney, and the "moral force men" led by Lovett and Bronterre O'Brien. The latter considered that the working class had not sufficient strength to achieve reform alone and should now invite the aid of sympathetic middle-class groupings: O'Connor and his allies declared that the middle-class reformers, responsible for the deception of 1832, were also the worst oppressors of the operatives in the factories and mines. O'Connor, with the assistance of his journal the *Star*, which secured a hitherto unparalleled circulation, carried the day and drove the other section out of the movement. His popularity became enormous, due to his hard work, his hatred of the middle class and his remarkable invective, of which the following is a specimen: "You—I was just coming to you when I was describing the materials of which our spurious aristocracy is composed. You, gentlemen, belong to the big-bellied, little-brained, numskull aristocracy. How dare you hiss me, you contemptible set of platterfaced, amphibious politicians?" A national organization, technically illegal, called the National Charter Association, was founded, which gave some coherence to the movement. It secured the allegiance of a number of trade union branches and promoted a second petition which received the startling number of 3,315,752 signatures. The year 1842, when this was presented, marks the high water-mark of Chartism. After its rejection on May 2, the Chartist executive turned an existing small strike at Ashton into a general strike for the Charter (Aug. 12). They brought out Lancashire, Cheshire, the Potteries and several other industrial districts; the strikers marching from town to town knocking the plugs out of the boilers where resistance was offered (hence the name Plug Riots). Owing to inadequate communications, the strike spread slowly, but trades as far north as Aberdeen had decided to come out, when, his nerve failing, O'Connor suddenly declared the strike was a plot of the Anti-Corn Law League. This action broke up the strike which ended almost at once in defeat. Thereafter Chartism entered into a period of decline, in which interest was chiefly directed to a financially unsound scheme for settling Chartists on the land as smallholders, by means of a National Land Company directed by O'Connor. One settlement only (O'Connorville, 1847, Herringsgate, Bucks) was opened. Enthusiasm was revived in 1847 by the election of O'Connor as M.P. for Nottingham, and in 1848 by the sensational series of revolutions on the continent. Fired by the hope of similar victories, O'Connor promoted a petition, which he said had 6,000,000 signatures, and arranged for the calling of a "National Assembly." The petition was to be presented by a procession of Chartists marching from Kennington Common to the House of Commons on April 10 1848. Believing this to be the day fixed for the revolution, the Government garrisoned London so heavily that the procession was abandoned. The petition, further, was announced by the Government to contain under 2,000,000 signatures, and it was also discovered that the Land Company was bankrupt. Under the influence of this series of fiascos, O'Connor became distracted in his mind: his successor, Ernest Jones, endeavoured in vain to revive the legal movement which by about 1854 may be regarded as extinct. The illegal revolutionary organization prepared an insurrection for Whit, Monday 1848, later adjourned to Aug. 15, but as it was carefully

watched and, indeed, partly directed by police informers, its effort was suppressed without difficulty.

The disappearance of Chartism was due not so much to the folly of its leaders as to the increasing comfort of the working class in the period of prosperity following on the Corn Law Repeal (1846), and the enforcement of the factory reforms secured by Lord Shaftesbury (*q.v.*). Working-class interest henceforward was diverted to the co-operative movement and the new craft trade unions, of which the most famous, the Amalgamated Society of Engineers, was founded in 1851.

BIBLIOGRAPHY.—There are two *Histories of the Chartist Movement*, both unfinished, by Mark Hovell (1917) and Julius West (1920). See also M. Beer, *History of British Socialism* 2 vols. (1919, 1920). Lovett, *Life and Struggles of William Lovett* (republished 1920); *Trial of John Frost under a special Commission of Oyer and Terminer* (1840); Francis Place's mss. (Brit. Mus., Add mss. 27,819-21), and the file of the *Northern Star*. (R. W. P.)

CHARTRES, a city of north-western France, capital of the department of Eure-et-Loir, 55 m. south-west of Paris on the railway to Le Mans. Pop. (1926) 20,687. Chartres is on the left bank of the Eure, on a hill crowned by its famous cathedral, the spires of which are a landmark on the plain of Beauce, "the granary of France." The Eure, which divides into three branches, is crossed by several bridges, some ancient, and is fringed by remains of fortifications, notably the Porte Guillaume (14th century) flanked by towers. The steep, narrow streets of the old town contrast with the boulevards which encircle it and divide it from the suburbs. The cathedral of Notre-Dame (*see* ARCHITECTURE: *Romanesque*, and *Gothic Architecture*; and CATHEDRAL), was founded by Bishop Fulbert (11th century) on the site of a church which had been destroyed by fire. In 1194 another fire made new building necessary and the present church was finished by 1240; there have been minor additions and alterations since that time. A fire in 1836 destroyed the upper woodwork. The statuary of the portals, the stained glass of the 13th century, and the choir-screen of the Renaissance are all unique. The south spire, the Clocher Vieux (351 ft. high), dates from the 12th century; the Clocher Neuf (377 ft.) was not completed till the 16th century. The cathedral is 440 ft. long, its choir measures 150 ft. across, and the vaulting is 121 ft. high. The abbey church of St. Pierre, chiefly 13th century, contains fine stained glass and twelve representations of the apostles in enamel (1547) by Léonard Limosin. St. Martin-au-Val is a 12th century church. The hôtel de ville (17th century) contains a museum and library, an older hôtel de ville is of the 13th century, and there are mediaeval and Renaissance houses.

Chartres was one of the principal towns of the Carnutes, and by the Romans was called *Autricum*, from the river *Autura* (Eure), and afterwards *civitas Carnutum*. It was burnt by the Normans in 858, and unsuccessfully besieged by them in 911. It was in English hands 1417-32. It was attacked unsuccessfully by the Protestants in 1568, and was taken in 1591 by Henry IV., who was crowned there three years afterwards. It was seized by the Germans on Oct. 21, 1870, and used as a centre of operations. During the middle ages it gave its name to a countship held by the counts of Blois and Champagne and afterwards by the house of Châtillon, a member of which in 1286 sold it to the crown. It was raised to the rank of a duchy in 1528 by Francis I.

The town is the seat of a bishop, a prefecture, a court of assizes, and has tribunals of first instance and of commerce and a chamber of commerce. It is a market-town for Beauce. Game-pies of Chartres are well known, and industries include flour-milling, timber-sawing, brewing, distilling, iron-founding, leather manufacture, dyeing, and the manufacture of stained glass, billiard requisites, hosiery, machinery, etc.

CHARTREUSE. A celebrated liqueur, green and yellow, made at La Grande Chartreuse, the old Carthusian monastery

near Grenoble. The Carthusian order of monks was founded by Saint Bruno of Cologne in 1084. In 1607 the Maréchal d'Estrées gave to the Carthusian Fathers the recipe of the elixir. It was supposed to be concocted from a distillation of herbs, culled on the slopes of the Dauphiné valley, and, the finest brandy. In 1757 Brother Gêrôme Maubec, "a very clever apothecary," perfected the formula, the secret of which, however, was never divulged nor discovered by analysis. In the Revolution of 1793 the Carthusians were despoiled of their property but they retained the secrecy of their formula. In 1816 they were allowed to return to their beloved monastery. In 1880 the Carthusian fathers were obliged to protect their liqueur by means of trade-marks. In 1901, having declined to accept indulgence from the Decree for the expulsion of the Religious Orders from France, they locked themselves in their monastery; but, in consequence of the law against Associations, they were expelled. Their distillery at Fourvoire was sold by auction, including their trade-mark. They emigrated to Farneta, near Lucca, in Italy, and transferred their distillery to Tarragona in Spain.

Their new position involved them in a number of lawsuits in France and elsewhere, the object being to show that they were still the owners in foreign countries of the trade-marks of which they had been deprived in France, and that they still retained the secret formula of their liqueur with the right to use it anywhere. The liqueur that they now make is sold under the name of Liqueur des Pères Chartreux. It is supposed to be identical with the old liqueur but connoisseurs profess to be able to detect a difference due, probably, to the herbs being gathered in an alien soil. A movement to secure the return of the Carthusians to their old monastery is developing; should it succeed the original Chartreuse would be revived. Meanwhile the old stocks are diminishing year by year. The name of the printer, Alier, on the label is the only evidence of authenticity. (J. V. M.)

CHARTREUSE, LA GRANDE, the mother house of the order of Carthusian monks (*see* CARTHUSIANS). It is situated in the French department of the Isère, about 12½ m. N. of Grenoble, at a height of 3,205 ft. above the sea, in the heart of a group of limestone mountains, and not far from the source of the Guiers Mort. The original settlement here was founded by St. Bruno about 1084, and derived its name from the small village to the south-east, formerly known as Cartusia, and now as St. Pierre de Chartreuse. The first convent on the present site was built between 1132 and 1137, but the actual buildings date only from about 1676, the older ones often having been burnt. One of the most famous of the early Carthusian monks was St. Hugh of Lincoln, who lived here from 1160 to 1181, when he went to England to found the first Carthusian house at Witham in Somerset; in 1186 he became bishop of Lincoln, and before his death in 1200 had built the angel choir and other portions of the cathedral here.

The monks were expelled in 1793, but were allowed to return in 1816, when they had to pay rent for the use of the buildings and the forests around. They were again expelled in 1904, and are dispersed in various houses in England, at Pinerolo (Italy) and at Tarragona (Spain). (*See* above.) The high roofs of dark slate, the cross-surmounted turrets and the lofty clock-tower are the chief features of the buildings of the convent, which are not very striking. Women were formerly lodged in the old infirmary, close to the main gate, which is now a hotel. Within the conventual buildings are four halls formerly used for the reception of the priors of various branch houses in France, Italy, Burgundy and Germany. The very plain and unadorned chapel dates from the 15th century, but the cloisters, around which cluster the 36 small houses for the fully professed monks, are of later date. The library contained before the Revolution a very fine collection of books and mss., most of them now in the town library at Grenoble.

CHARWOMAN. A word of interesting origin, meaning one who is hired to do occasional household work. "Char" or "chare," which forms the first part of the word, is common, in many forms, to Teutonic languages, meaning a "turn," and, in this original sense, is seen in "ajar," properly "on char," of a door "on the turn" in the act of closing. It is thus applied to a "turn of work," an odd

job, and is so used, in the form "chore," in the United States, and in dialects of the south-west of England.

CHASE, SALMON PORTLAND (1808-1873), American statesman and jurist, was born in Cornish, N.H., on Jan. 13, 1808. His father died in 1817, and the son passed several years (1820-24) in Ohio with his uncle, Bishop Philander Chase (1775-1852), the foremost pioneer of the Protestant Episcopal Church in the West. He graduated at Dartmouth college in 1826, and after studying law under William Wirt, attorney-general of the United States, in Washington, D.C., was admitted to the bar in 1829, and removed to Cincinnati, O., in 1830. Here he soon gained a position of prominence at the bar.

At a time when public opinion in Cincinnati was largely dominated by Southern business connections, Chase, influenced probably by James G. Birney, associated himself after about 1836 with the anti-slavery movement, and became recognized as the leader of the political reformers as opposed to the Garrisonian abolitionists. To the cause he freely gave his services as a lawyer, and was particularly conspicuous as counsel for fugitive slaves seized in Ohio for rendition to slavery under the Fugitive Slave law of 1793—indeed, he came to be known as the "attorney-general of fugitive slaves." His argument (1847) in the famous Van Zandt case before the United States Supreme Court attracted particular attention, though in this as in other cases of the kind the judgment was against him. In brief he contended that slavery was "local, not national," that it could exist only by virtue of positive State law, that the Federal Government was not empowered by the Constitution to create slavery anywhere, and that "when a slave leaves the jurisdiction of a State he ceases to be a slave, because he continues to be a man and leaves behind him the law which made him a slave."

In 1841 he abandoned the Whig Party, with which he had previously been affiliated, and for seven years was the undisputed leader of the Liberty Party in Ohio; he was remarkably skilful in drafting platforms and addresses, and it was he who prepared the national Liberty platform of 1843 and the Liberty address of 1845. Realizing in time that a third-party movement could not succeed, he took the lead during the campaign of 1848 in combining the Liberty Party with the Barnburners or Van Buren Democrats of New York to form the Free-Soilers. He drafted the famous Free-Soil platform, and it was largely through his influence that Van Buren was nominated for the presidency. His object, however, was not to establish a permanent new party organization, but to bring pressure to bear upon Northern Democrats to force them to adopt a policy opposed to the further extension of slavery.

In 1849 he was elected to the United States Senate as the result of a coalition between the Democrats and a small group of Free-Soilers in the State legislature; and for some years thereafter, except in 1852, when he rejoined the Free-Soilers, he classed himself as an Independent Democrat, though he was out of harmony with the leaders of the Democratic Party. During his service in the Senate (1849-55) he was pre-eminently the champion of anti-slavery in that body, and no one spoke more ably than he did against the Compromise Measures of 1850 and the Kansas-Nebraska bill of 1854. The Kansas-Nebraska legislation, and the subsequent troubles in Kansas, having convinced him of the futility of trying to influence the Democrats, he assumed the leadership in the North-west of the movement to form a new party to oppose the extension of slavery. The "Appeal of the Independent Democrats in Congress to the People of the United States," written by Chase and Giddings, and published in the *New York Times* of Jan. 24, 1854, may be regarded as the earliest draft of the Republican Party creed. He was the first Republican governor of Ohio, serving from 1855 to 1859.

Although, with the exception of Seward, he was the most prominent Republican in the country, and had done more against slavery than any other Republican, he failed to secure the nomination for the presidency in 1860, partly because his views on the question of protection were not orthodox from a Republican point of view, and partly because the old line Whig element could not forgive his coalition with the Democrats in the senatorial campaign of 1849; his uncompromising and conspicuous anti-slavery

record, too, was against him from the point of view of "availability." As secretary of the Treasury in President Lincoln's cabinet in 1861-64, during the first three years of the Civil War, he rendered services of the greatest value. That period of crisis witnessed two great changes in American financial policy, the establishment of a national banking system and the issue of a legal tender paper currency. The former was Chase's own particular measure. He suggested the idea, worked out all of the important principles and many of the details, and induced Congress to accept them. The success of that system alone warrants his being placed in the first rank of American financiers. It not only secured an immediate market for Government bonds, but it also provided a stable uniform national currency.

Perhaps Chase's chief defect as a statesman was an insatiable desire for supreme office. It was partly this ambition, and also temperamental differences from the president, which led him to retire from the cabinet in June 1864. A few months later (Dec. 6, 1864) he was appointed chief justice of the United States Supreme Court to succeed Judge Taney, a position which he held until his death. Toward the end of his life he gradually drifted back toward his old Democratic position, and made an unsuccessful effort to secure the nomination of the Democratic Party for the presidency in 1872. He died in New York city on May 7, 1873. Chase was one of the ablest political leaders of the Civil War period, and deserves to be placed in the front rank of American statesmen.

The standard biography is A. B. Hart's *Salmon Portland Chase in the "American Statesmen Series"* (1899). Less philosophical, but containing a greater wealth of detail, is J. W. Shuckers' *Life and Public Services of Salmon Portland Chase* (1874). R. B. Warden's *Account of the Private Life and Public Services of Salmon Portland Chase* (Cincinnati, 1874) deals more fully with Chase's private life. See also Floyd Pershing Gates, *Salmon P. Chase and the Independent Democrats* (1918); and Arthur M. Schlesinger, *Salmon Portland Chase, Undergraduate and Pedagogue* (1919).

CHASE, SAMUEL (1741-1811), American jurist, was born in Somerset county (Md.), April 17, 1741. He was admitted to the bar at Annapolis in 1761, and for more than 20 years was a member of the Maryland legislature. He took an active part in the resistance to the Stamp Act, and from 1774 to 1778 and 1784 to 1785 was a member of the Continental Congress. He did much to persuade Maryland to advocate a formal separation of the 13 colonies from Great Britain, and signed the Declaration of Independence on Aug. 2, 1776. In 1791 he became chief judge of the Maryland general court, but resigned in 1796 to become associate justice of the U.S. Supreme Court. Because of his activities on behalf of the Federalist party, the House of Representatives adopted a resolution of impeachment in March, 1804, and on Dec. 7, 1804, the House managers, chief among whom were John Randolph, Joseph H. Nicholson (1770-1817), and Caesar A. Rodney (1772-1824), laid their articles of impeachment before the Senate. The trial, which lasted from Jan. 2 to March 1, 1805, ensued on an indictment of eight articles, dealing with his conduct in the Fries and Callender trials, with his treatment of a Delaware grand jury, and (in article viii.) with his making "highly indecent, extrajudicial" reflections upon the national administration. On only three articles was there a majority against Judge Chase, the largest, on article viii., being four short of the necessary two-thirds to convict.

"The case," says Henry Adams, "proved impeachment to be an impracticable thing for partisan purposes, and it decided the permanence of those lines of constitutional development which were a reflection of the common law." Judge Chase resumed his seat on the bench, and occupied it until his death, June 19, 1811.

See *The Trial of Samuel Chase* (2 vols., Washington, 1805), reported by Samuel H. Smith and Thomas Lloyd; an article in *The American Law Review*, vol. xxxiii. (St. Louis, 1899); and Henry Adams's *History of the United States*, vol. ii. (1889). See also J. H. Hazelton, *The Declaration of Independence* (1906); and *The Maryland Signers of the Declaration of Independence* (Baltimore, 1912).

CHASE, WILLIAM MERRITT (1849-1916), American painter, was born at Franklin, Ind., on Nov. 1, 1849. He was a pupil of B. F. Hays in Indianapolis, of J. O. Eaton in New York and of A. Wagner and Piloty in Munich. In New York he established a school of his own, after having taught with success for

some years at the Art Students' League. A worker in all mediums—oils, water-colour, pastel and etching—painting with distinction the figure, landscape and still life, he is perhaps best known by his portraits, his sitters numbering some of the most important men and women of his time.

Chase won many honours at home and abroad, became a member of the National Academy of Design, New York, and for ten years was president of the Society of American Artists. In 1912 he was awarded the Proctor Prize by the National Academy of Design for his "Portrait of Mrs. H." At the Panama Pacific Exposition (1915) a special room was assigned to his works. Among his most important canvases are "Ready for the Ride" (Union League Club, N.Y.), "The Apprentice," "Court Jester," and portraits of the painters, Whistler and Duveneck; of General Webb and of Peter Cooper.

See J. Walker McSpadden, *Famous Painters of America* (1916).

CHASE. (1) The pursuit of wild animals for food or sport (Fr. *chasse*, Lat. *capere*, to take), and so the pursuit of anything. (See HUNTING.) The word was also applied to park land reserved for the breeding and hunting of wild animals; cf. various place-names in England, as Cannock Chase. It is also a term for a stroke in tennis (q.v.). (2) An enclosure (Fr. *châsse*, Lat. *capsa*, a box), such as the muzzle-end of a gun in front of the trunnions; or, in typography (q.v.) the frame enclosing the page of type. (See PRINTING.)

CHASE NATIONAL BANK, THE, of the city of New York was founded on Sept. 12, 1877. Its first published balance sheet (Dec. 27, 1877), showed total resources of \$1,042,009.25. On October 3, 1928, the total resources were \$1,156,340,254.36—over a thousand times greater. Of these total resources, \$821,832,766.47 were the result of natural growth and \$334,507,487.89 were acquired by consolidation with other smaller institutions:

| | |
|--|------------------|
| Nov. 22, 1921 Metropolitan Bank | \$ 75,856,249.21 |
| Jan. 12, 1925 American Foreign Banking Corp. | 11,528,383.05 |
| Apr. 10, 1926 Mechanics and Metals National Bank | 234,834,368.80 |
| Dec. 28, 1927 Mutual Bank | 12,288,486.83 |

As of October 3, 1928, the capital of the Chase Bank was \$60,000,000, surplus \$60,000,000, undivided profits \$18,807,343.06. Until 1911, the Chase was primarily a "bankers' bank," holding the reserve balances of other banks throughout the country. Since that date, its commercial and industrial deposits have become relatively far more important, although it has maintained and increased its activities as a correspondent for out-of-town banks.

The American Express Company with its world-wide banking facilities was acquired through stock ownership by the Chase Securities Corporation, July 1, 1929. The National Park Bank and its affiliates were merged on August 24, 1929. These acquisitions brought the capital of the bank to \$105,000,000 with a surplus of like amount. (J. McH.)

CHASING, the art of producing figures and ornamental patterns, either raised or indented, on metallic surfaces by means of steel tools or punches. (See SILVERSMITHS' AND GOLDSMITHS' WORK.) The chaser first outlines the pattern on the surface he is to ornament, after which, if the work requires bold or high embossments, this is blocked out by a process called "snarling." The snarling iron is a long iron tool turned up at the end, and made so that when securely fastened in a vice the upturned end can reach and press against any portion of the interior of the vase or object to be chased. The part to be raised being held firmly against the upturned point of the snarling iron, the workman gives the shoulder or opposite end a sharp blow which raises the surface of the metal held against the tool. When the blocking out from the interior is finished, the object to be chased is filled with molten pitch, which is allowed to harden. It is then fastened to a sandbag, and with hammer and a multitude of small punches of different outline the details of the pattern (lined, smooth or "mat") are worked out. Embossing and stamping from steel dies and rolled ornaments have taken the place of chased ornamentations in the cheaper kinds of plated works. (See EMBOSsing.)

CHASLES, MICHEL (1793-1880), French mathematician, was born on Nov. 15, 1793, at Epervon. He was educated at Paris, and engaged in business, which he later gave up for the

study of mathematics. Chasles was made professor of geodesy and mechanics at the Polytechnic school and later professor of higher geometry at the Sorbonne. He and Steiner independently elaborated modern projective geometry, but the interchange of scientific ideas was so poor that the former did not know of the work of the latter. Chasles used his "method of characteristics" and his "principle of correspondence" to solve many problems; the solutions were published in a series of papers in *Comptes Rendus*. The problem of the attraction of an ellipsoid on an external point was solved by him in 1846. Many of his original memoirs were later published in the *Journal de l'École Polytechnique*. Chasles wrote two text-books, *Higher Geometry* (1852) and *Conic Sections* (1865). His *Aperçu historique sur l'origine et le développement des méthodes en géométrie* (1837) is a standard work, the subject being continued in *Rapport sur le progrès de la géométrie* (1870). Chasles died in Paris on Dec. 18, 1880.

CHASLES, PHILARÈTE (1798-1873), French critic and man of letters, was born at Mainvilliers (Eure et Loir). His father, P. J. M. Chasles (1754-1826), was a member of the Convention, and brought up his son according to the principles of Rousseau's *Émile*. Philarète, after a régime of outdoor life, followed by some years of classical study, was apprenticed to a printer. He contributed to the *Revue des deux mondes*, until he had a violent quarrel, terminating in a lawsuit, with François Buloz, who won his case. He became librarian of the Bibliothèque Mazarine, and from 1841 was professor of comparative literature at the Collège de France. During his active life he produced some 50 volumes of literary history and criticism and of social history.

Among his best critical works is *Dix-huitième Siècle en Angleterre* . . . (1846), one of a series of 20 vols. of *Études de littérature comparée* (1846-75), which he called later *Trente ans de critique*. An account of his strenuous boyhood is given in his *Maison de mon père*. His *Mémoires* (1876-77) did not fulfil the expectations based on his brilliant talk.

CHASSÉ, a gliding step in dancing, so called since one foot is brought up behind, or chases, the other. The *chassé croisé* is a double variety of the step.

CHASSELOUP-LAUBAT, FRANÇOIS, MARQUIS DE (1754-1833), French general and military engineer, was born at St. Sernin (Lower Charente), and entered the French engineers in 1774. In 1791 he was promoted captain, and his ability was recognized in the campaigns of 1792. After serving as chief engineer at the siege of Mainz (1796), he was sent to Italy, where he conducted the first siege of Mantua, and afterwards to the new Rhine frontier of France. He was chief of engineers in the army of Italy in 1799, and Napoleon's engineer general in 1800; and he was afterwards employed in reconstructing the defences of the famous Quadrilateral in northern Italy (1801-05). His *chef-d'œuvre* was the great fortress of Alessandria on the Tanaro. Chasseloup served in Napoleon's campaign of 1806-07, directing the sieges of Colberg, Danzig and Stralsund; and again in 1809, in Italy. Soon after his last campaign, in Russia (1812), he retired from active service, and was made a peer of France and a knight of St. Louis by Louis XVIII. He voted in the chamber of peers against the condemnation of Marshal Ney. In politics he belonged to the constitutional party.

As an engineer Chasseloup was an adherent, though of advanced views, of the old bastioned system. His front was applied to Alessandria, as has been stated, and contains many elaborations of the bastion trace, with, in particular, masked flanks in the tenaille, which served as extra flanks of the bastions. The bastion itself was carefully and minutely retrenched. The ordinary ravelin he replaced by a heavy casemated caponier after the example of Montalembert, and, like Bousmard's, his own ravelin was a large and powerful work pushed out beyond the glacis.

Chasseloup's only published works were, *Correspondance d'un général français avec un général autrichien*. (1801; republ. 1803 or 1809 as *Correspondance de deux généraux* . . .) and *Extraits de Mémoires sur quelques parties de l'artillerie et de fortifications* (Milan, 1805; republ. 1811 as *Essais sur quelques parties* . . .). The most important of his papers are in ms. in the Dépôt of Fortifications, Paris.

CHASSEPOT, officially "fusil modèle 1866," a military breech-loading rifle, famous as the arm of the French forces in

the Franco-German War of 1870-71. It was called after its inventor, Antoine Alphonse Chassepot (1833-1905), who had previously constructed a series of experimental forms of breech-loader, and it became the French service weapon in 1866. In the following year it made its first appearance on the battlefield at Mentana, where it inflicted severe losses upon Garibaldi's troops. In the war of 1870 it proved very greatly superior to the German needle-gun. The breech was closed by a bolt very similar to those of more modern rifles, and amongst the technical features of interest were the method of obturation and the retention of the paper cartridge. It was sighted to 1,312 yd. (1,200 metres).

CHASSÉRIAU, THÉODORE (1819-1856), French painter, was born in the Antilles on Sept. 20, 1819, and died in Paris on Oct. 8, 1856. He studied under Ingres at Paris and at Rome, subsequently falling under the influence of Paul Delaroche. In his short life he produced little. There are decorative paintings by him in the church of St. Méry and the Salle des Comptes in the Palais d'Orsay, and some characteristic lithographs, imaginative in character and original in execution, which link him with the artists of the '70s and '80s rather than with his contemporaries or predecessors.

CHASSEURS, light infantry or cavalry regiments in the French army (from Fr. *chasser*, to hunt). The first light infantry (*chasseurs à pied*) units were raised in 1743, and by 1794 their number had increased to 21 battalions. The name then disappeared until 1840, but by 1870 they had again increased to their original figure, and by the outbreak of the World War to 30 battalions, of which 12 were known as *Chasseurs Alpins*, and were specially equipped and trained for mountain warfare. Under the existing French army organization these 30 battalions of *chasseurs* are formed as independent units for administrative purposes, but are grouped into demi-brigades of three battalions for war. They are distinguished from line infantry by their dark blue uniform.

The light cavalry (*chasseurs à cheval*) regiments, which were first instituted in 1779, and had a distinguished record of service down to the close of the World War, are now represented only by the five regiments of *Chasseurs d'Afrique*, which were originally recruited for service in Algeria, but performed notable service in the European campaigns of the Second Empire. The peace and war organization of these *Chasseurs d'Afrique* regiments corresponds in general to that of a line cavalry unit. The corps of *chasseurs forestiers* is a semi-military body of game-keepers and forest guards, intended to act as guides and intelligence agents in time of war.

CHASSIS. Properly, a window-frame. The word is French, meaning a frame, from which is derived "sash." It is in general use for that part of a motor-vehicle consisting of the wheels, frame and machinery, on which the body or carriage part rests. The word has passed into aeronautics, and is also used for the movable traversing frame of a gun.

CHASTELARD, PIERRE DE BOCZOZEL DE (1540-1563), French poet, was born in Dauphiné, a scion of the house of Bayard. His name is inseparably connected with Mary, Queen of Scots. From the service of the Constable Montmorency, Chastelard, then a page, passed to the household of Marshal Damville, whom he accompanied on his journey to Scotland in escort of Mary (1561). He returned to Paris in the marshal's train, but left for Scotland again shortly afterwards, bearing letters of recommendation to Mary from his old protector, Montmorency, and the *Regrets* addressed to the ex-queen of France by Pierre Ronard, his master in the art of song. He undertook to transmit to the poet the service of plate with which Mary rewarded him. But he had fallen in love with the queen, who is said to have encouraged his passion. The young man hid himself under her bed, where he was discovered by her maids of honour. Mary pardoned the offence, but Chastelard was so rash as again to violate her privacy. He was discovered a second time, seized, sentenced and hanged the next morning. He met his fate valiantly and consistently, reading, on his way to the scaffold, his master's noble *Hymne de la mort*, and turning at the instant of doom towards the palace of Holywood, to address to his unseen mistress the famous farewell—"Adieu, toi si belle et si cruelle, qui me tues et que je ne puis

cesser d'aimer." This at least is the version of the *Mémoires* of Brantôme.

CHASTELLAIN, GEORGES (c. 1415-1475), Burgundian poet and chronicler, was a native of Alost, in Flanders. He saw active service in the Anglo-French Wars and elsewhere. In 1434 he received a gift from Philip the Good, duke of Burgundy, for his military service. After the peace of Arras (1435) he abandoned soldiering for diplomacy. The next ten years were spent in France, where he was connected with Georges de la Trémoille, and afterwards entered the household of Pierre de Brézé, at that time seneschal of Poitou, by whom he was employed on missions to the duke of Burgundy, in an attempt to establish better relations between Charles VII. and the duke. On the further breach between the two princes, Chastellain left the French service to enter Philip's household, and in 1457 he became a member of the ducal council. He was continually employed on diplomatic errands until 1455, when he was made Burgundian historiographer. He worked at his *Chronique*, with occasional interruptions in his retreat to fulfil missions in France, or to visit the Burgundian court. He was assisted, from about 1463 onwards, by his disciple and continuator, Jean Molinet, whose rhetorical and redundant style may be fairly traced in some passages of the *Chronique*. Chastellain died at Valenciennes on Feb. 13 (according to the treasury accounts), or on March 20 (according to his epitaph), 1475. Only about one-third of the whole *Chronique*, which extended from 1419 to 1474, is extant.

Among his contemporaries Chastellain acquired a reputation by his poems and occasional pieces. He was no mere annalist, but proposed to fuse and shape his vast material to his own conclusions, in accordance with his political experience. The most interesting feature of his work is the skill with which he pictures the leading figures of his time.

The known extant fragments of Chastellain's *Chroniques* with his other works were edited by Kervyn de Lettenhove for the Brussels Academy in 1863-66 (Brussels) as *Oeuvres de Georges Chastellain*. This edition includes three volumes of minor pieces of considerable interest, especially *Le Temple de Boccace*, dedicated to Margaret of Anjou, and the *Dépréciation* for Pierre Brézé, imprisoned by Louis XI. The attribution to Chastellain is in some cases erroneous, notably in the case of the *Livre des faits de Jacques de Lalaing*, which is probably the work of Lefèbvre de Saint-Remi, herald of the Golden Fleece. In the allegorical *Oultré d'amour* it has been thought a real romance between Brézé and a lady of the royal house is concealed.

See A. Molinier, *Les Sources de l'histoire de France*; notices by Kervyn de Lettenhove prefixed to the *Oeuvres* and in the *Biographie nationale de Belgique*; and an article by Vallet de Viriville in the *Journal des savants* (1867).

CHASUBLE, a liturgical vestment of the Catholic Church, being the outermost garment worn by bishops and priests when celebrating the Mass. The word is derived, through the French, from the Latin *casula*, a little house or hut. Since the chasuble (or *planeta*, as it is also called in the Roman Missal) is only used at the Mass, or rarely for functions intimately connected with the sacrament of the altar, it may be regarded as the Mass vestment *par excellence*. According to the prevailing model in the Roman Catholic Church it is a scapular-like cloak, with a hole in the middle for the head, falling down over breast and back, and leaving the arms uncovered at the sides. Its shape and size, however, differ considerably in various countries (see fig.), while some churches—e.g., those of certain monastic orders—have retained or reverted to the earlier "Gothic" forms to be described later. According to the decisions of the Congregation of Rites, chasubles must not be of linen, cotton or woollen stuffs, but of silk; though a mixture of wool (or linen and cotton) and silk is allowed if the silk completely cover the other material on the outer side.

The chasuble, like the kindred vestments in the Eastern Churches, is derived from the Roman *paenula* or *planeta*, a cloak worn by all classes and both sexes in the Graeco-Roman world (see VESTMENTS).

At the Reformation the chasuble was rejected with the other vestments by the more extreme Protestants. Its use, however,

survived in the Lutheran churches; and though in those of Germany it is no longer worn, it still forms part of the liturgical costume of the Scandinavian Evangelical churches. In the Church of England, though it was prescribed alternatively with the cope in the first prayer-book of Edward VI., it was ultimately discarded with the other "Mass vestments." (See VESTMENTS.)

Form.—The chasuble was originally a tent-like robe which fell in loose folds below the knee of the wearer. Its inconvenience, however, was obvious, and a process of cutting away at the sides began, which continued until the tent-shaped chasuble of the 12th century had developed in the 16th into the present scapular-like vestment. This process was, moreover, hastened by the substitution of costly and elaborately embroidered materials for the simple stuffs of which the vestment had originally been composed: for, as it became heavier and stiffer, it had to be made smaller.

Decoration.—Chasubles were until the 10th century generally quite plain, and even at the close of this century, when the custom of decorating the chasuble with orphreys (*q.v.*) had become common, there was no definite rule as to their disposition. From this time onward, the embroidery became ever more and more elaborate, and the orphreys were broadened to allow of their being decorated with figures. About the middle of the 13th century, the cross with horizontal arms begins to appear on the back of the vestment, and by the 15th this had become the most usual form. Sometimes the back of the chasuble has no cross, but only a vertical orphrey, and in this case the front, besides the vertical stripe, has a horizontal orphrey just below the neck opening. This latter is the type used in the local Roman Church, which has been adopted in certain dioceses in South Germany and Switzerland, and of late years in the Roman Catholic churches in England, *e.g.*, Westminster cathedral.

The earlier decoration of the forked cross, *i.e.*, a vertical orphrey with two arms turned upwards over the shoulders, was commonly retained in England and has thus been largely adopted by the "Anglo-Catholic" clergy in modern times. Father Braun gives proof that this decoration was not even originally conceived as a cross at all, citing early instances of its having been worn by laymen and even by non-Christians. It was not until the 13th century that the symbolical meaning of the cross began to be elaborated, and this was accentuated from the 14th century onward by the custom of adding to it the figure of the crucified Christ and other symbols of the Passion. This, however, did not represent any definite rule; and the orphreys of chasubles were decorated with a great variety of pictorial subjects. The local Roman Church, true to its ancient traditions, adhered to the simpler forms. The modern Roman chasuble, besides the conventional arabesque pattern, is decorated, according to rule, with the arms of the archbishop and his see.

The Eastern Church.—The original equivalent of the chasuble is the phelonion, from the Lat. *paenula*. It is a vestment of the type of the Western bell chasuble; but, instead of being cut away at the sides, it is either gathered up or cut short in front. In the Armenian, Syrian, Chaldaean and Coptic rites it is cope-shaped. The phelonion is not in the East so specifically a eucharistic vestment as in the West, but is worn at other solemn functions besides the liturgy, *e.g.*, marriages, processions. The Greek and Greek Melchite metropolitans now wear the *sakkos* instead of the phelonion; and in the Russian, Ruthenian, Bulgarian and Italo-Greek churches this vestment has superseded the phelonion in the case of all bishops (see DALMATIAN and VESTMENTS).

See J. BRAUN, S. J., *Die liturgische Gewandung* (1907), pp. 149–247, Dom H. Leclercq, in Cabrol, *Dict. d'Archéol. Chrét. et de Liturgie*, and the bibliography to the article VESTMENTS.

COMPARATIVE SIZES AND SHAPES OF CHASUBLES AS NOW IN USE IN VARIOUS COUNTRIES (A & B) GERMAN, (C) ROMAN, (D) SPANISH

CHATALJA LINES, a fortified position 25m. W. of and covering Constantinople, extending from the Black sea at Karaburnu to the Sea of Marmara at Buyuk Chekmedje. They form a very strong position, covered in part by lakes and marshes, and commanding all the country to the west. They were first constructed during the Russo-Turkish war of 1877–78, but were not at that time the scene of fighting. During the Balkan war of 1912, however, they afforded a secure refuge to the Turkish armies defeated in the open field by the Bulgarians, and when the latter attacked them in mid-November of that year, with insufficient artillery preparation, they were repulsed with heavy loss. In the World War the lines were once more reconditioned in expectation of an Allied attack on Constantinople.

CHÂTEAU, the French word for castle (*q.v.*). The development of the castle in the 15th and 16th centuries into houses arranged rather for residence than defence led to a corresponding widening of the meaning of the term *château*, which came to be applied to any seigniorial residence and so generally to all country houses of any pretensions (*cf.* the Germ. *Schloss*). The French distinguish the fortified from the residential type by describing the former as the *château fort*, the latter as the *château de plaisance*. The development of the one into the other is admirably illustrated by the *châteaux* scattered along the Loire. Of these, Langeais, still in perfect preservation, is a fine type of the *château fort*, with its 10th century keep and 13th century walls. Amboise (1490), Blois (1500–40), Chambord (begun 1526), Chenonceaux (1515–60), Azay-le-Rideau (1521), may be taken as typical examples of the *château de plaisance* of the transition period, all retaining some of the architectural characteristics of the mediæval castle. In English the word *château* is often used to translate foreign words, *e.g.*, *Schloss*, meaning country house or mansion.

See RENAISSANCE ARCHITECTURE. For the Loire *châteaux* see Theodore Andrea Cook, *Old Touraine* (1892).

(T. F. H.)

CHATEAUBRIAND, FRANÇOIS RENÉ, VICOMTE DE (1768–1848), French author, youngest son of René Auguste de Chateaubriand, comte de Combourg, was born at St. Malo on Sept. 4, 1768. He was a brilliant representative of the reaction against the ideas of the French Revolution, and the most conspicuous figure in French literature during the First Empire. His naturally poetical temperament was fostered in childhood by picturesque influences, the mysterious reserve of his morose father, the ardent piety of his mother, the traditions of his ancient family, the legends and antiquated customs of the sequestered Breton district, above all, the vagueness and solemnity of the neighbouring ocean. His closest friend was his sister Lucille,¹ a passionate-hearted girl, divided between her devotion to him and to religion. François received his education at Dol and Rennes. From Rennes he proceeded to the College of Dinan, to prepare for the priesthood, but decided, after a year's holiday at the family *château* of Combourg (1786) to enter the army. In 1788 he received the tonsure in order to enter the order of the Knights of Malta. In Paris (1787–89) he met La Harpe, Évariste Parny, "Pindare" Lebrun, Nicolas Chamfort, Pierre Louis Ginguené, and others, of whom he has left portraits in his memoirs. In 1791 he departed for America to take part in a romantic scheme for the discovery of the North-West Passage. The passage was not found or even attempted, but the adventurer returned from his seven months' stay in America enriched with new ideas and new imagery. In 1792 he married Mlle. Céleste Buisson de Lavigne, a girl of 17, who brought him a small fortune. He then joined the *émigrés*, and after many vicissitudes reached London, where he lived in great poverty.

From his English exile (1794–99) dates the *Natchez* (first printed in his *Oeuvres complètes*, 1826–31), a prose epic portraying the life of the Red Indians. Two brilliant episodes originally designed for this work, *Atala* and *René*, are famous. Chateaubriand's first publication, however, was the *Essai historique, politique et moral sur les révolutions* . . . (London, 1797), which the author subsequently retracted, but did not suppress. In this volume he appears as a mediator between royalist and revolution-

¹Her *Oeuvres* were edited in 1879, with a memoir, by Anatole France.

ary ideas, a free-thinker in religion, and a disciple of Rousseau. A great change in his views was, however, at hand, induced, if we accept his own statement, by a letter from his sister Julie (Mme. de Farcy), telling him of the grief his views had caused his mother, who had died soon after her release from the Conciergerie in the same year. His brother had perished on the scaffold in April 1794, and both his sisters, Lucile and Julie, and his wife had been imprisoned at Rennes. Mme. de Farcy did not long survive her imprisonment.

On Chateaubriand's return to France in 1800 the *Génie du christianisme* was already in an advanced state. Chateaubriand's favourite resort in Paris was the salon of Pauline de Beaumont, who was to fill a great place in his life, and gave him some help in the preparation of his book. *Atala, ou les amours de deux sauvages dans le désert*, used as an episode in the *Génie du christianisme*, appeared separately in 1801 and immediately made his reputation. Alike in its merits and defects the piece is a more emphatic and highly coloured *Paul et Virginie*. The *Génie du christianisme, ou beautés de la religion chrétienne*, appeared in 1802, upon the eve of Napoleon's re-establishment of the Catholic religion in France. No coincidence could have been more opportune, and Chateaubriand esteemed himself the counterpart of Napoleon in the intellectual order. The work is not to be judged by its apologetics, but as a masterpiece of literary art. Its influence in French literature was immense. The *Éloa* of Alfred de Vigny, the *Harmonies* of Lamartine and even the *Légende des siècles* of Victor Hugo may be said to have been inspired by the *Génie du christianisme*. At the moment of publication it admirably subverted the statecraft of Napoleon, and Talleyrand in 1803 appointed the writer *attaché* to the French legation at Rome, whither he was followed by Mme. de Beaumont, who died there.

When his insubordinate and intriguing spirit compelled his recall he was transferred as envoy to the canton of the Valais. The murder of the duke of Enghien (March 21, 1804) took place before he took up this appointment. Chateaubriand immediately resigned his post. In 1807 he offended Napoleon by an article in the *Mercure de France* (July 4), containing allusions to Nero which were rightly taken to refer to the emperor. The *Mercure*, of which he had become proprietor, was temporarily suppressed, and was in the next year amalgamated with the *Décade*. In 1806, he had made a pilgrimage to Jerusalem, undertaken in quest of new imagery. He returned by way of Tunis, Carthage, Cadiz and Granada. At Granada he met Mme. de Mouchy, and the place and the meeting apparently suggested the romantic tale of *Le Dernier Abencérage*, which, for political reasons, remained unprinted until the publication of the *Oeuvres complètes* (1826-31). The journey also produced *L'Itinéraire de Paris à Jérusalem* . . . (3 vols., 1811), and inspired his prose epic, *Les Martyrs, ou le triomphe de la religion chrétienne* (2 vols., 1809). *René* had appeared in 1802 as an episode of the *Génie du christianisme*, and a separate unauthorized edition appeared at Leipzig. The tale forms a connecting link in European literature between *Werther* and *Childe Harold*; it paints the misery of a morbid and dissatisfied soul. Chateaubriand betrayed amazing egotism in describing his sister Lucile in the *Amélie* of the story, and much is obviously descriptive of his own early surroundings. With *Les Natchez* his career as an imaginative writer is closed. In 1831 he published his *Études ou discours historiques* . . . (4 vols.) dealing with the fall of the Roman empire.

Chateaubriand's vanity and ambition made him dangerous and untrustworthy as a political associate. He was forbidden to deliver the address he had prepared (1811) for his reception to the Academy on M. J. Chénier on account of the bitter allusions to Napoleon contained in it. From this date until 1814 Chateaubriand lived in seclusion at the Vallée-aux-loups, an estate he had bought in 1807 at Aulnay. His pamphlet *De Bonaparte, des Bourbons, et de la nécessité de se rallier à nos princes légitimes*, appeared on March 31, 1814, the day of the entrance of the allies into Paris. Louis XVIII. declared that it had been worth a hundred thousand men to him. Chateaubriand, as minister of the interior, accompanied him to Ghent during the Hundred Days, and for a time associated himself with the excesses of the royalist

reaction. But he rapidly drifted into liberalism and opposition, and was disgraced in Sept. 1816 for his pamphlet *De la monarchie selon la charte*. He had to sell his library and his house of the Vallée-aux-loups.

After the fall of his opponent, the duc Decazes, Chateaubriand obtained the Berlin embassy (1821), from which he was transferred to London (1822), and he also acted as French plenipotentiary at the Congress of Verona (1822). He here made himself mainly responsible for the iniquitous invasion of Spain. He was foreign minister for a brief period, and then, after another interlude of effective pamphleteering in opposition, accepted the embassy to Rome in 1827, under the Martignac administration, but resigned it at Prince Polignac's accession to office.

During the first half of Louis Philippe's reign he wrote a *Mémoire sur la captivité de madame la duchesse de Berry* (1833) and other legitimist pamphlets; but as the prospect of his again performing a conspicuous part diminished, he relapsed into an attitude of complete discouragement. His *Congrès de Vérone* (1838), *Vie de Rancé* (1844), and his translation of Milton, *Le Paradis perdu de Milton* (1836), belong to the writings of these later days. He died on July 4, 1848, affectionately tended by his old friend Madame Récamier, herself deprived of sight. For the last 15 years of his life he had been engaged on his *Mémoires*, and his chief distraction had been his daily visit to Madame Récamier, at whose house he met the European celebrities. He was buried in the Grand Bé, an islet in the bay of St. Malo. Shortly after his death appeared his celebrated *Mémoires d'outre-tombe* (12 vols., 1849-50). These memoirs undoubtedly reveal his vanity, his egotism, the frequent hollowness of his professed convictions, and his incapacity for sincere attachment, except, perhaps, in the case of Madame Récamier. Though the book must be read with the greatest caution where others are concerned, it is perhaps now the most read of all his works.

Chateaubriand is chiefly significant as marking the transition from the old classical to the modern romantic school. The fertility of ideas, vehemence of expression and luxury of natural description, which he shares with the romanticists, are controlled by a discipline learnt in the school of their predecessors. His palette, always brilliant, is never gaudy; he is not merely a painter but an artist. He is a master of epigrammatic and incisive sayings. Perhaps, however, the most truly characteristic feature of his genius is the peculiar magical touch which Matthew Arnold indicated as a note of Celtic extraction, which supplies an element of sincerity to Chateaubriand's declamation. Egotism was his master-passion. He is a signal instance of the compatibility of genuine poetic emotion, of sympathy with the grander aspects both of man and nature, and of munificence in pecuniary matters, with absorption in self and general sterility of heart.

BIBLIOGRAPHY.—The *Oeuvres complètes* of Chateaubriand were printed in 28 vols., 1826-31; in 20 vols., 1829-31; and in many later editions, notably in 1858-61, in 20 vols., with an introductory study by Sainte-Beuve. The principal authority for Chateaubriand's biography is the *Mémoires d'outre-tombe* (1849-50), of which there is an English translation, *The Memoirs of . . . Chateaubriand* (6 vols., 1902), by A. Teixeira de Mattos, based on the edition (4 vols., 1899-1901) of Edmond Biré. This work should be supplemented by the *Souvenirs et correspondances tirés des papiers de Mme. Recamier* (2 vols., 1859, ed. Mme. Ch. Lenormant). See also Comte de Marcelus, *Chateaubriand et son temps* (1859); the same editor's *Souvenirs diplomatiques; correspondance intime de Chateaubriand* (1858); C. A. Sainte-Beuve, *Chateaubriand et son groupe littéraire sous l'empire* (2 vols., 1861, new and revised ed., 3 vols., 1872); other articles by Sainte-Beuve, who was in this case a somewhat prejudiced critic, in the *Portraits contemporains*, vols. i. and ii.; *Causeries du lundi*, vols. i., ii. and x.; *Nouveaux Lundis*, vol. iii.; *Premiers Lundis*, vol. iii.; A. Vinet, *Études sur la litt. française au XIX^e siècle* (1849); M. de Lesclapart, *Chateaubriand* (1892) in the *Grands écrivains français*; Émile Faguet, *Études littéraires sur le XIX^e siècle* (1887); and *Essai d'une bio-bibliographie de Chateaubriand et de sa famille* (Vannes, 1896), by René Kerviler. Joseph Bédier, in *Études critiques* (1903), deals with the American writings, and there is an admirable criticism of the *Génie du christianisme* in F. Brunetière's *Hist. de la litt. française* vol. iv. (1917). Some correspondence with Sainte-Beuve was edited by Louis Thomas in 1904, and some letters to Mme. de Staël appeared in the *Revue des deux mondes* (Oct. 1903).

CHÂTEAUBRIANT, a town of western France, capital of an arrondissement in the department of Loire-Inférieure, on the

left bank of the Chère, 40m. N.N.E. of Nantes by rail. Pop. (1926) 6,985. It takes its name from a castle founded in the 11th century by Brient, count of Penthievre, remains of which still exist though it was shattered in 1488. The new castle, begun in 1524 by Jean de Laval, and famous in history as the residence of Françoise de Foix, mistress of Francis I., has a beautiful colonnade running at right angles to the main building. It was presented to the department by the duc d'Aumale in 1852. The interesting Romanesque church is dedicated to St. Jean de Béré. Châteaubriant is the seat of a subprefect and has a tribunal of first instance. It is an important centre on the Ouest-État railway, and has lime-kilns and agricultural trade.

CHÂTEAU-D'OEX, resort, Switzerland, 20½ m. from Montreux, in the Sarine valley, 3,182 feet above sea-level, below the north-west end of the Bernese Oberland. Pop. 3,464. The castle has been replaced by a church and the village has many attractive chalets scattered on the hillside, which are enriched with pine woods. The village is much frequented both in summer and in winter, and summer and winter sports are well developed.

CHÂTEAUDUN, a town of north central France, capital of an arrondissement in the department of Eure-et-Loir, 28 m. S.S.W. of Chartres. Pop. (1926) 5,819. It stands on high ground near the left bank of the Loir. The streets radiate from a central square, the town being replanned after fires in 1723 and 1870.

Châteaudun (*Castrodunum*), which dates from the Gallo-Roman period, was in the middle ages the capital of the countship of Dunois. The château was built in great part by Count Jean and his descendants. Founded in the 10th and rebuilt in the 12th and 15th centuries, it consists of a principal wing adjoined by a chapel. To the left of the courtyard rises a 12th century lofty keep. The church of La Madeleine dates from the 12th century; the buildings of the abbey to which it belonged are occupied by the subprefecture, the law court and the hospital. St. Valérien, St. Jean and the ruined chapel of Notre-Dame du Champdé are mediaeval in date. There is a tribunal of first instance. Flour-milling, tanning and leather-dressing, and the manufacture of silver jewellery and machinery are carried on. Trade is in cattle, grain, wool and hemp.

CHÂTEAU-GONTIER, a town of western France in the arrondissement of Laval in the department of Mayenne on the Mayenne, 18 m. S. by E. of Laval. Pop. (1926) 5,951. Château-Gontier owes its origin and its name to a castle erected in the first half of the 11th century by Gunther, the steward of Fulk Nerra of Anjou, on the site of a farm belonging to the monks of St. Aubin d'Angers. On the extinction of the family, the lordship was assigned by Louis XI. to Philippe de Comines. The church of St. Jean, a relic of the castle, dates from the 11th-12th centuries. The town suffered severely during the wars of the League. In 1793 it was occupied by the Vendéans. It manufactures serge and flannel and is an agricultural market.

CHÂTEAU-RENAULT, FRANÇOIS LOUIS DE ROUSSELET, MARQUIS DE (1637-1716), French admiral, entered the army in 1658, but in 1661 was transferred to the navy. His early services were mostly performed in cruises against the Barbary pirates (1672). When war broke out between England and France after the Revolution of 1688, he was in command at Brest, and was chosen to carry the troops and stores sent by the French king to the aid of James II. in Ireland. Although he was watched by Admiral Herbert (Lord Torrington, *q.v.*), with whom he fought an indecisive action in Bantry bay, he executed his mission with success. Château-Renault commanded a squadron under Tourville at the battle of Beachy Head in 1690. He was with Tourville in the attack on the Smyrna convoy in 1693.

On the death of Tourville in 1701 he was named to the vacant post of vice-admiral of France. On the outbreak of the War of the Spanish Succession he was charged with the protection of the Spanish ships which were to bring the treasure from America. His fleet of 15 French and three Spanish warships, having under their care 12 galleons, had anchored on Sept. 22 in Vigo bay. Official obstacles were placed in the way of landing the treasure.

At last the order came, and the bullion was landed under the care of the Galician militia which was ordered to escort it to Lugo. The bulk of the merchandise was on board the galleons when the allied fleet appeared outside of the bay on Oct. 22, 1702. Sir George Rooke and his colleagues resolved to attack. The fleet was carrying a body of troops which had been sent out to make a landing at Cadiz, and had been beaten off. The fortifications of Vigo were weak on the sea side, and on the land side there were none. The fleet of 24 sail was steered at the boom which Château-Renault had erected and broke through it, while the troops turned the forts and scattered the Galician militia. In the bay the action was utterly disastrous to the French and Spaniards. The booty was far less than the allies hoped, but the damage to the French and Spanish Governments was great.

The king considered Château-Renault free from blame, and must indeed have known that the admiral had been trusted with too many secrets to make it safe to inflict a public rebuke. The Spanish Government declined to give him the rank of grandee which was to have been the reward for bringing the bullion safely home. But in 1703 he was made a marshal of France, and shortly afterwards lieutenant-general of Brittany. In 1708 on the death of his nephew he inherited the marquisate, and on Nov. 15, 1716, he died in Paris.

A life of Château-Renault was published in 1903 by J. J. R. Calmon-Maison. There is a French as well as an English account of the part played by him at Bantry bay and Beachy Head, and the controversy still continues. For the French history of the navy under Louis XIV. see Léon Guérin, *Les Marins illustres* (1861), and *Histoire maritime de la France*, vols. iii, iv. (1863).

CHÂTEAUROUX, MARIE ANNE DE MAILLY-NESLE, DUCHESSE DE (1717-1744), mistress of Louis XV. of France, was the fourth daughter of Louis, marquis de Nesle. In 1740, upon the death of her husband, the marquis de la Tournelle, she supplanted her sister, Madame de Mailly, as titular mistress in 1742. Directed by the duc de Richelieu, she tried to arouse the king, dragging him off to the armies, and negotiated the alliance with Frederick II. of Prussia in 1744. Her political rôle, however, has been exaggerated.

See Ed. and J. de Goncourt, *La Duchesse de Châteauroux et ses soeurs* (new ed. 1889); *Histoire de Madame de Châteauroux tirée des mémoires de la Duchesse de Brancas* (1919).

CHÂTEAUROUX, a town of central France, capital of the department of Indre, situated on the left bank of the Indre, 88 m. S. of Orleans on the main line of the Orleans railway. Pop. (1926) 22,226. The old town, close to the river, forms a nucleus round which a newer and more extensive quarter, bordered by boulevards, has grown up; the suburbs of St. Christophe and Déols (*q.v.*) lie on the right bank of the river. Châteauroux owes its name and origin to the castle founded about the middle of the 10th century by Raoul, prince of Déols, which later passed to Henry II. of England, falling eventually to the Condé family (1612). The present Château-Raoul dates from the 14th and 15th centuries and forms part of a charming river-side landscape. The old Église des Cordeliers (13th century) contains a museum and a library with the oldest extant ms. of the "Chanson de Roland." The modern church of St. André is very tastefully planned in the Gothic style. Châteauroux is the seat of a prefect and of a court of assizes. It has tribunals of first instance and of commerce and a board of trade-arbitrators and a chamber of commerce. The manufacture of textiles and machinery are actively carried on and there is a state tobacco factory.

CHÂTEAU-THIERRY, a town of northern France, in the department of Aisne, 59 m. E.N.E. of Paris on the Eastern railway to Nancy. Pop. (1926) 7,246. Château-Thierry is built on rising ground on the right bank of the Marne, over which a fine stone bridge leads to the suburb of Marne. On the top of a hill are the ruins of a castle, said to have been built by Charles Martel for the Frankish king, Thierry IV., whence the name of the town. The chief relic is a gateway flanked by massive round towers, known as the Porte Saint-Pierre. A belfry of the 15th century and the church of St. Crépin (Crispin) of the same period are of some interest.

Château-Thierry was formerly the capital of the district of Brie Pouilleuse, and received the title of duchy from Charles IX. in 1566. It was captured by the English in 1421, by Charles V. in 1544, and sacked by the Spanish in 1591. During the wars of the Fronde it was pillaged in 1652; and in the campaign of 1814 it suffered severely, under Blücher, the Russo-Prussian forces being beaten by Napoleon in the neighbourhood. It was the farthest point reached by the Germans in their offensive of May 27, 1918. The 2nd and 3rd Divs. of the American Expeditionary Force were sent to the Marne in the Château-Thierry region to assist the hard-pressed French forces. At Château-Thierry itself a U.S. machine-gun battalion took part in the successful defence of the river-crossing, while to the west of the town the 2nd Div., under General Bundy, fought the fiercely contested engagement of Belleau Wood. (See GERMAN OFFENSIVE; MARNE, SECOND BATTLE OF THE.)

La Fontaine was born in the town in 1621. His house is still preserved in the street that bears his name.

The distinctive industry is the manufacture of mathematical and musical instruments. There is trade in the white wine of the neighbourhood, and in agricultural products. Gypsum, millstone and paving-stone are quarried in the vicinity.

CHÂTELAIN, in France originally merely the equivalent of the English castellan, *i.e.*, the commander of a castle. With the growth of the feudal system, however, the title gained in France a special significance which it never acquired in England, as implying the jurisdiction of which the castle became the centre. The *châtelain* was originally, in Carolingian times, an official of the count; with the development of feudalism the office became a fief, and so ultimately hereditary. In this as in other respects the *châtelain* was the equivalent of the viscount (*q.v.*); sometimes the two titles were combined, but more usually in those provinces where there were *châtelains* there were no viscounts, and vice versa. The title *châtelain* continued also to be applied to the inferior officer, or *conciergerie châtelain*, who was merely a castellan in the English sense. The power and status of *châtelains* necessarily varied greatly at different periods and places; occasionally they were great nobles with an extensive jurisdiction, as in the Low Countries (see BURGRAVE). The *châtellenie* (*castellania*), or jurisdiction of the *châtelain*, as a territorial division for certain judicial and administrative purposes, survived the disappearance of the title and office of the *châtelain* in France, and continued till the Revolution.

See Achille Luchaire, *Manuel des institutions françaises* (1892); Du Cange, *Glossarium*, s. "Castellanus."

CHATELAINE, the mistress of a castle. From the custom of a chatelaine of carrying the keys of the castle suspended from her girdle, the word was applied in the late 19th century to the collection of short chains, worn by ladies to which keys, penknife, needlecase, scissors, etc., were attached.

CHÂTELET, the word, sometimes also written *castillet*, used in France for a building designed for the defence of an outwork or gate, sometimes of great strength or size, but distinguished from the *château*, or castle proper, in being purely defensive and not residential (from Med. Lat. *castella*). In Paris, before the Revolution, this word was applied both to a particular building and to the jurisdiction of which it was the seat. This building, the original Châtelet, had been first a castle defending the approach to the Cité. Tradition traced its existence back to Roman times, and in the 18th century one of the rooms in the great tower was still called the *chambre de César*. The jurisdiction was that of the provostship (*prévôté*) and viscountship of Paris, which was certainly of feudal origin, probably going back to the counts of Paris.

It was not till the time of St. Louis that, with the appointment of Étienne Boileau, the provostship of Paris became a *prévôté en arde*, *i.e.*, a public office no longer put up to sale. When the *baillis* (see BAILIFF AND BAILIE) were created, the provost of Paris naturally discharged the duties and functions of a *bailli*, in which capacity he heard appeals from the seigniorial and inferior judges of the city and its neighbourhood, keeping, however, his title of provost. When under Henry II. certain *bailliages* became

presidial jurisdictions (*présidiaux*) *i.e.* received to a certain extent the right of judging without appeal, the Châtelet, the court of the provost of Paris, was made a presidial court, but without losing its former name. Finally, various tribunals peculiar to the city of Paris, *i.e.*, courts exercising jurisdictions outside the common law or corresponding to certain *cours d'exception* which existed in the provinces, were united with the Châtelet, of which they became divisions (*chambres*). Thus the lieutenant-general of the police made it the seat of his jurisdiction, and the provost of the Île de France, who had the same criminal jurisdiction as the provosts of the marshals of France in other provinces, sat there also. As to the *personnel* of the Châtelet, it was originally the same as in the *bailliages*, except that after the 14th century it had some special officials, the auditors and the examiners of inquests. Like the *baillis*, the provost had lieutenants who were deputies for him, and in addition gradually acquired a considerable body of *ex officio* councillors. This last staff, however, was not yet in existence at the end of the 14th century, for it is not mentioned in the *Registre criminel du Châtelet* (1389-92), published by the Société des Bibliophiles Français. In 1674 the whole *personnel* was doubled at the time when the new Châtelet was established side by side with the old, the two being soon after amalgamated. On the eve of the Revolution it comprised, beside the provost whose office had become practically honorary, the *lieutenant civil* who presided over the *chambre de prévôté au parc civil* or court of first instance; the *lieutenant criminel*, who presided over the criminal court; two *lieutenants particuliers*, who presided in turn over the *chambre du présidial* or court of appeal from the inferior jurisdictions; a *juge auditeur*; 64 councillors (*conseillers*); the *procureur du roi*, four *avocats du roi*, and eight *substituts*, *i.e.* deputies of the *procureur* (see PROCUR-

THE CHÂTELET, PARIS, ORIGINALLY A FORTRESS, LATER A PRISON AND COURTHOUSE, AS IT LOOKED BEFORE ITS DESTRUCTION IN 1802

RATOR), beside a host of minor officials. Under the Revolution the Constituent Assembly empowered the Châtelet to try cases of *lèse-nation*, and it was also before this court that was opened the inquiry following on the events of Aug. 5 and 6, 1789. It was suppressed by the law of Aug. 16, 1790, together with the other tribunals of the *ancien régime*. (J. P. E.)

CHÂTELLERAULT, a town of western France, capital of an arrondissement in the department of Vienne, 19 m. N.N.E. of Poitiers on the Orleans railway. Pop. (1926) 13,258. It is situated on the right bank of the Vienne and is connected with the suburb of Châteauneuf by a stone bridge of the 16th and 17th centuries. Châtellerault (or Châtelherault: *Castellum Airdaldi*) derives its name from a fortress built in the 10th century by

Airaud, viscount of its territory. In 1515 it was made a duchy in favour of François de Bourbon, but was soon reunited to the crown. In 1548 it was bestowed on James Hamilton, 2nd earl of Arran (*see* HAMILTON). The manufacture of cutlery dates from the 14th century and is carried on in villages along the banks of the Clain. The most important industrial establishment is the national small-arms factory, established in 1819.

CHATHAM, EARL OF, WILLIAM PITT (1708-1778), was born at Golden square, Westminster, on Nov. 15, 1708. His father was Robert, son of the famous governor Pitt of Madras, who sold to the Regent Orleans his great diamond still to be seen in the Louvre; his mother Harriet Villiers, daughter of Viscountess Grandison, a notable character in her day. He was the fourth child of a family of six, of whom his elder brother Thomas inherited the governor's Cornish property, Beconnoc, and the youngest, his favourite sister Ann, attained some note in the world that Horace Walpole adorned. At the age of ten or 11 he was sent to Eton and in Jan. 1727 to Trinity college, Oxford. He showed no remarkable genius at either place, but obtained a sound classical education and came to know many of those with whom he was afterwards associated: Lyttelton, the Grenvilles, two Foxes, Hanbury Williams, Pratt and Henry Fielding at Eton, while Henley, the Wesleys, Samuel Johnson and Murray were his contemporaries at Oxford. But after a year he had to leave Oxford owing to the persistent gout which had already got hold of him and he spent some months studying law at the university of Utrecht. By this time, when he was barely 20 most of his natural protectors were dead, including his father, his uncle, the soldier-statesman Lord Stanhope, who used to delight in his nephew's martial spirit and call him the "young marshal," and the grim old governor who loved the boy and said of him "he is a hopeful lad and doubt not he will answer yours and all his friends expectations." But he had good friends in the Grenvilles, who procured him a cornetcy in their uncle Lord Cobham's regiment of Horse, which later became the 1st Dragoon Guards. In spite of a small income of little more than £200 and though he took his military training more seriously than most, he made many friends in the political world and found time and money to make another, his last, journey abroad, in the course of which he had a passing love affair and at Lyons saw the confluence of the Rhone and Saône which, 20 years later, gave him a hint for one of his most famous speeches.

A Commoner.—In 1735 his real career began when he obtained a seat in the House of Commons for Old Sarum, one of his brother's pocket-boroughs. Naturally he joined the opposition to Walpole, to which all his young friends belonged, under the leadership of Carteret, Chesterfield, Wyndham and Pulteney, with the prince of Wales as their patron and Bolingbroke their mentor. Pitt's maiden speech was delivered in the following year on an address moved by the opposition to congratulate the king on the prince's marriage. Except for some back-handed compliments to the king and covert allusions to the notorious dissensions in the royal family, the speech as reported hardly seems to account for its results. "We must muzzle this terrible cornet of horse," exclaimed Walpole and forthwith deprived him of his commission. At any rate this deprivation did Pitt no harm, for he obtained a better post in the prince's household: and his fame was made. Walpole too lived to regret it, for no speeches made from the opposition benches during the last years of his administration on the commercial disputes with Spain and on the conduct of the war, into which Walpole was finally goaded, were so pointed, so bitter and so damaging as Pitt's. Pitt, indeed, with that engaging frankness characteristic of his public utterances, subsequently admitted that on the main object of Walpole's policy, an accommodation with Spain on the vexed question of the right of search, he was wrong and Walpole right. But this his first duel with a great parliamentary leader is chiefly remarkable for the revelation of his power of giving expression to the opinions of important sections of the community, such as the commercial men and even the colonists beyond the sea, hardly represented in the close oligarchy of parliament. In one of his speeches, for example, he called on the House to remember "the two millions of people

in your American colonies," so apt to be forgotten, and to condemn Walpole's policy because "the complaints of your despairing merchants,—the voice of England has condemned it." Thus early he showed the source of his strength and of his influence as the Great Commoner by seeking for the national will and the national policy, not within the walls of a corrupt and unrepresentative House of Commons, but in the hearts of the people of England itself.

On Walpole's fall in 1742 the new ministry was constituted, largely owing to Walpole's influence behind the curtain, chiefly of men not prepared to carry the vendetta against him to extremes. It included his old colleagues Newcastle and Hardwicke; Carteret was appeased by the post of Secretary of State; Pulteney was silenced by a peerage; and Cobham's Boy Patriots, of whom Pitt was now the leading figure, were excluded. Pitt indeed secured a committee to enquire into Walpole's conduct during his ministry, but got little satisfaction from its half-hearted proceedings. For the next two years he devoted himself to compassing Carteret's downfall.

Growing Influence.—Carteret, that downright and arresting figure of the 18th century with his genius for foreign affairs, had one principle in common with Pitt, a determination to overthrow the exorbitant power of the Bourbons in Europe, which both regarded as the standing menace to England. But they differed essentially in their methods. In the confusing war of the Austrian Succession (1741-48) Carteret could only see a purely continental issue and though, like Pitt, he was anxious to secure Frederick's support, he was mainly concerned in forming a great coalition of German states under the leadership of England and Hanover to support Maria Theresa in her struggle with France; in this aim he found support from George II., who was always preoccupied with the safety of his German electorate. Pitt on the other hand thought we were wasting our efforts in forming German alliances, always onerous and expensive, and made the most of the popular prejudice against the king's German dominions, maintaining that our true policy was to devote ourselves entirely to the duel with France in our proper sphere at sea and in attacks on France's colonial possessions, which threatened English enterprise and expansion both in America and in India. Hence he attacked Carteret even more bitterly than he had Walpole in a series of philippics in which full rein was given to his unrivalled power of invective. "A desperate rhodomontading minister," "An infamous minister, who seems to have renounced the name of an Englishman," "A Hanover troop minister, a flagitious taskmaster, whose only party are the 16,000 Hanoverians, the placemen by whose means he has conquered the cabinet,"—such are some of the gems of invective which abound in Pitt's attacks on Carteret's policy of continental alliances and Hanoverian subsidies. Even more in keeping with Pitt's lifelong views was his denunciation of Carteret's secret methods and his refusal to "gain the confidence of the people" for his measures. This secrecy, more than anything else, proved Carteret's undoing, for he was as secret with his colleagues as with parliament and people; in 1744, finding that the cabinet refused any longer to honour his blank cheques, he resigned.

The way now seemed open to Pitt; for the Pelhams, now in the ascendant, felt they could no longer dispense with so formidable an orator. But unfortunately Pitt had grievously wounded the king's tenderest feelings by his attacks on Hanover, "a despicable electorate," as he called it, and by derogatory remarks about the battle of Dettingen; the king absolutely refused to have him in his closet. It required a further exhibition of Pitt's power over the House and in the country and of his patriotic spirit during the '45, when he was consulted by all and looked up to as almost the only effective and vigorous statesman; it required too the resignation of the Pelham ministry in 1746 before the king recalled them a few days later on their own terms, which included a post for Pitt, first as Vice-Treasurer for Ireland, and shortly afterwards as Paymaster.

A Disinterested Paymaster.—The duties of Paymaster then, as now, were not onerous, but the pickings were not to be despised. It was the custom for the Paymaster to put out at interest on his own account the large lump sums paid over to him at the

beginning of a year for subsequent disbursement; as he had not to hand over any surplus balances he might have accumulated till the end of his term of office, the profits from this source were very large. It was also customary for the Paymaster to accept a commission of $\frac{1}{4}\%$ on every subsidy to a foreign prince, of which there were many at that time. Pitt resolutely set his face against these practices and after holding the office for nine years left it a poor man but with a resounding reputation for disinterestedness among his countrymen. He also introduced some useful reforms for the benefit of the recipients of pay and pensions.

Domestic Life.—He had leisure during the next seven years, two of them in war-time and the remainder uneasy years of preparation for the Seven Years' War, to give a general support to the Pelham administration. He could also afford to indulge in his passion for landscape gardening, both on his friends' estates and in the grounds of South Lodge, Enfield, that he purchased for himself, to seek at various spas mitigation for his almost incessant attacks of gout, and to allow himself the grandiose scale of expenditure that he affected especially in generosity to his friends. For, in addition to his salary of about £4,000, in 1744 he had received a legacy of £10,000 from the old duchess of Marlborough "upon account of his merit in the noble defence he has made of the laws of England, and to prevent the ruin of his country." But though he had many warm friends bound to him, says a contemporary, by his "private good qualities, friendship beyond professions, industry and ability to oblige," yet he was essentially a solitary man, especially after a rift in the affection of himself and his favourite sister Ann. Fortunately in the autumn of 1754 he suddenly woke up to his love for Hester, the one sister of his five Grenville friends; and at one of their places, Wotton, with its "deep shades of oak, softening lawns and tranquil waters, like a lively smile lightening up a thoughtful countenance," discovered his love to her and received the admission of hers. On Nov. 16 following they were quietly married in London; and so began one of the happiest unions that it has ever befallen the fate of a great statesman to find, blessed as it was with a perfect understanding between the two and soon with the added joys of happy parenthood. Pitt was especially fortunate in finding a home where he could be certain of abiding trust and sympathy at this time, for he was on the eve of his most arduous struggle as a prelude to those wonderful five years when he bore the whole weight of a decisive war upon his shoulders.

The Great Commoner.—Until Pelham's death during the year 1754, though not always entirely approving of the ministry's policy, he had supported it in war and peace, without surrendering his right of protest against measures which ran counter to his fundamental principles. He strove vainly to give the last period of the war a colonial and maritime bias, away from the futile campaigns on the continent; and during the years of peace set his face against Pelham's too drastic economies on the navy, which he always regarded as our chief weapon of offence and defence; he also protested against Newcastle's expensive and pusillanimous policy of seeking protection by subsidy treaties with a crowd of German princelings. But on Pelham's death he was driven to more forcible measures. Newcastle, on whom Pelham's mantle fell, though unrivalled as a parliamentary manager, was no statesman and had the weak man's jealousy of eminence in that line. Pitt was incontestably the greatest leader in the House of Commons, but for that very reason Newcastle feared to put the leadership in his hands. His only possible rival was Henry Fox, but Newcastle forced Pitt and Fox into temporary alliance against him by placing over them Robinson, a worthy nonentity. The two great orators baited poor Robinson beyond endurance and forced him to resign whereupon Newcastle was reduced to taking Fox, as the less eminent of the two, to fill his place. Pitt naturally felt himself betrayed by Fox's desertion and transferred his attacks to him, being inspired in one debate to compare the junction of the feeble Newcastle and the vehement Fox with his recollection of "the conflux at Lyons of the Rhone and the Saône: this a feeble, languid stream, and, though languid, of no depth—the other a boisterous and overbearing torrent—but they meet at last; and long may they continue united,

to the comfort of each other, and to the glory, honour and happiness of this nation." This jibe cost Pitt the Pay Office.

But it would not do. The war began with the defeat of Braddock on the Monongahela and the loss of Minorca, while the old German muddle seemed likely to be repeated with the proposals to hire troops from Hesse, Brunswick and Saxony and a treaty with Russia for an invasion of Germany in defence of Hanover and a few months later another with Prussia to prevent any foreign power entering on German soil. The popular demand for Pitt became irresistible and Pitt was ready to respond to the demand. "I know," he said, "that I can save this country and that no one else can." In Nov. 1756 he formed a ministry without Newcastle and with Devonshire as its nominal head: but even a Pitt with the whole country at his back could not stand against Newcastle's parliamentary legions, so in June 1757 the ministry was reconstituted on the understanding that Newcastle should wield all the patronage and Pitt bend his whole mind to the war. Never was division of labour more effectual.

America and India.—Pitt was determined that this should be a national war. He got rid of German mercenaries who had been sent over to resist invasion and revived the ancient militia, which he made a serviceable defence force; he saw to it that England "should put herself on board her fleet," by finding her the necessary ships and men; he united all parties not only in the House but throughout the country by appeals "captivating of the people" and above all gave them confidence by enunciating a courageous and intelligible war policy. America and India he fastened upon as the main objects of our strategy, so to the first he sent out his main expeditions and gave his chief thoughts to elaborating the campaigns for the conquest of Canada; and to the East India Company and their "heaven-born general" Clive he lent invaluable support in their struggle against the French East India Company. But not content with these main fields of operation he saw that a colonial empire could best be won by also distracting France in other parts of the world. He attacked her on her own coasts, in Africa, in the West Indies and above all kept her main armies and resources engaged in the duel with our ally Frederick by subsidizing him and sending a British force to guard his flank. He was of course accused of inconsistency in thus supporting a German war, but the essential difference between his policy and that of Carteret and Newcastle was that Germany was no longer the main object but subsidiary in the sense that he could boast that he had won America in Germany.

Not the least of his services was the new spirit he infused into his chosen generals, Wolfe, Amherst, Forbes; his admirals, Boscawen, Hawke, Saunders, Pocock, Watson; the American levies and assemblies who fought and paid for the common cause as they had never been willing to do before; and even the Highland levies, rebels ten years before, whom he had the courage to seek out "in their mountains of the north." Against such a minister directing so determined a national effort the Bourbon powers, even when they were united in 1761, were helpless. At the treaty of Paris in 1763, which consolidated the victories, England found herself supreme in North America and in India, had her Mediterranean base, Minorca, restored and gained territory both in Africa and the West Indies; but above all she had learned that she could fight best when she relied on herself.

Before the end of the war, however, Pitt had been forced to resign. George III., on his accession in 1760, at once showed his determination to bring the war to an end as speedily as possible in order to gain control of the government machinery monopolized by Newcastle and the Whigs, and to become himself head of the administration as the Patriot King. In his first speech to the Council he gave Pitt a taste of what was coming by describing the war as "bloody and expensive" and practically ignoring Frederick, the faithful ally to whom Pitt was committed. The introduction of Bute into the cabinet and its refusal in Oct. 1761 to forestall Spain's entry into hostilities by an immediate declaration of war, as Pitt advocated, led to his resignation and even to the momentary eclipse of his popularity by his acceptance of a pension and of a peerage for his wife.

But though the king had brought the war to an end in 1763,

by the Treaty of Paris, which Pitt had attacked in the House as an inadequate recognition of England's worldwide successes in the war, and by the resignation of Newcastle had obtained control of the government machinery of patronage and bribery, yet he was not happy in his ministers. Bute resigned after the Treaty of Paris, his successor George Grenville still thought he could lecture and dictate to the king as in the old halcyon days of Whig supremacy. Indeed the king soon came to the conclusion that the superficial resemblance between Pitt's principle of "measures not men" and his own desire for non-party government with individual ministers subservient to himself indicated Pitt as the most satisfactory refuge from his difficulties. Pitt had indeed opposed the measures promoted by the king against Wilkes and the use of general warrants as an infringement of the liberty of the subject and was known to disapprove of the Stamp Act passed by Grenville with the king's full approval; but he would have accepted office in 1765 had it not been for difficulties with his own followers. Thereupon the king was driven to accept the old Whig party under Rockingham.

The Earl of Chatham.—In the following year, however, when the Stamp Act had been repealed, and the Rockingham ministry found its position untenable owing to the intrigues of George III.'s creature Northampton, Pitt consented to form a ministry drawn from all sections of the House. The only chance for the success of such an experiment would have been complete control by Pitt himself: unfortunately his strength was waning and he chose the comparative ease of the House of Lords, being created earl of Chatham, and of the almost sinecure post of Lord Privy Seal. Even so he might have guided his heterogeneous team on the right lines had he been able to remain at his post. But a few months after assuming office his great mind temporarily gave way and he remained in retirement for close on two years, almost dead to the world and refusing even at the king's reiterated requests to see him or take any part in government. At the end of 1768 he roused himself, on some slights to his own personal followers, to resign the Privy Seal, but did not appear in the House of Lords till 1770, when for the first time he gave his peers a taste of that wonderful eloquence that had held the lower house spell-bound for so many years and had helped to earn for him the title of the Great Commoner. His principal subject of attack was on the conduct of the House of Commons in giving up its own privileges at the bidding of the king in the Wilkes case and in declaring that Luttrell, the candidate with a minority of votes, had been elected for Middlesex over Wilkes who headed the poll. He pressed for a dissolution to get rid of a corrupt and subservient House of Commons; he supported the City in its protests on behalf of civil liberty; and he once more dealt with the invasion of civil liberties through general warrants. In 1770 Chatham proposed to "infuse new health into the constitution" and neutralize its "rotten parts," the boroughs, by permitting "every county to elect one member more in addition to their present representation. The knights of the shire approach nearest to the constitutional representation of the country": and in the following year declared himself a convert to triennial parliaments, as a method of bringing parliament more into touch with the people. On foreign policy he sounded the alarm against the Bourbons as exemplified by Spain's high-handed seizure of the Falkland islands. But all his eloquence was to no purpose. He could not, nor was he perhaps, with his dictatorial disposition the man to unite the opposition, and, as his speeches were unreported to the nation, where lay his strength, they made little immediate impression on his apathetic colleagues.

America.—But the chief care of his last years was America. Though the Stamp Act had been repealed, largely as a result of a speech from Pitt, yet his own chancellor of the exchequer, Townshend, during Chatham's illness, had imposed other trifling duties, which brought in little revenue to England but irritated the Americans just as much as if they had been a serious financial burden. Attempts to enforce the obnoxious taxes led to violence in America, and repressive measures were adopted by the English government; by 1775 it had come to war.

Chatham from the outset laid down the principle that while the

imperial parliament might legitimately impose duties for the regulation of imperial trade, any tax levied solely on the Americans should only be voted by the Americans themselves. But Chatham's pleas against the government policy went far beyond legal distinctions. He loved the Americans for their British independence of spirit and he knew from his own experience in the war that they only needed appeals to their sense of justice and to their patriotism to become a "willing, giving people." "I rejoice that America has resisted," he told the House of Commons at the time of the Stamp Act: at this graver crisis, he told the Peers that "it is not repealing this act of parliament, it is not repealing a piece of parchment, that can restore America to our bosom; you must repeal her fears and her resentments; and you may then hope for her love and gratitude."

But he broke away from the Whigs when they were prepared to recognize the independence of America, even when she had cast in her lot with England's secular enemy, France; and he made his dying speech in the House of Lords in protest against any such diminution of an empire based on freedom, which he had done more than any living man to exalt. A few days later, after his collapse in the House of Lords, he died at his beloved country house at Hayes in Kent on May 11, 1778.

Broken by illness as he was during the last 15 years of his life and often almost despairing of his country, at least he was supremely happy in his private life, whether at Hayes in Kent, the house that he bought in 1756, sold ten years later, and bought again in 1767, or at Burton Pynsent in Somersetshire, left to him with an estate worth some £3,000 a year by Sir William Pynsent, a man who admired his services to the country but whom he had never seen. Here he was never too busy to train his five children to his own standard of love and service to England, finding in "the young statesman" William a readiness to follow in his own footsteps,—or to enter into their childish games or more dignified amusements such as private theatricals on classical subjects.

As an orator he was perhaps the greatest that England has produced, as one may guess even from the indistinct fragments that have come down to us by surreptitious reporting. Even in reading them one can understand something of what Charles Butler meant when he said that "every hearer was impressed with the conviction that there was something in him even finer than his words, that the man was infinitely greater than the orator"; while Grattan said of him: "He lightened upon the subject and reached the point by the flashings of his mind, which, like those of the eye, were felt but could not be followed." As a statesman his greatness was not only in the executive ability and clear vision of objectives which he manifested in his glorious five years as Secretary of State; but even more in the lessons he taught his countrymen, unheeding though they were at the time, of the spirit in which this empire of theirs was to be governed if it was to survive.

CHATHAM, a port and municipal and parliamentary borough of Kent, England, on the right bank of the Medway, 34 m. E.S.E. of London by the Southern railway. Pop. (1931) 42,996. Though a distinct borough it is continuous on the west with Rochester, and forms with it and New Brompton, on the east, one large town. The site on Chatham hill controlling the river entrance yielded human remains in the tumuli, pottery and coins.

Chatham (*Ceteham*, *Chetham*) belonged at the time of the Domesday Survey to Odo, bishop of Bayeux. During the middle ages it formed a suburb of Rochester, but Henry VIII. began to establish dockyards, and Elizabeth built a dockyard and estab-

lished an arsenal here. The dockyard was altered and improved by Charles I. and Charles II., and became the chief naval station of England. In 1708 an act was passed for extending the fortifications of Chatham. Henceforward the dockyard became the centre of attraction around which the town grew.

The Dockyard.—This covers an area of 516 ac. and has a river frontage of over 3 miles. It was brought into its present state by the extensive works begun about 1867. Before that time there was no basin or wet-dock, though the river Medway to some extent answered the same purpose, but a portion of the adjoining salt-marshes was then taken in, and three basins have been constructed, communicating with each other by means of large locks, so that ships can pass from the bend of the Medway at Gillingham to that at Upnor. Subsequent improvements included dredging operations in the Medway to improve the approach, and the provision of extra dry-dock accommodation under the Naval Works Acts. There are in all nine dry docks, one of which now takes first-class cruisers. The yard is equipped for building light class cruisers and refitting ships of all classes and for building submarines.

St. Mary's church was opened in 1903, but occupies a site in use since Saxon times. Stephen Borough (d. 1584), discoverer of the northern passage to Archangel in Russia (1553), is commemorated there. St. Bartholomew's chapel, originally attached to the hospital for lepers founded by Gundulph, bishop of Rochester, in 1070, is in part Norman. The funds for the maintenance of the hospital were appropriated to the hospital of St. Bartholomew, erected in 1863 within the boundaries of Rochester. The almshouse established in 1592 by Sir John Hawkins for seamen and shipwrights is still extant; the building was re-erected in the 19th century, while the fund called the Chatham Chest, originated by Hawkins and Drake in 1588, was incorporated with Greenwich hospital in 1802. The Naval hospital was opened in 1907 and replaces the old Melville hospital which was situated in Old Brompton. The Naval barracks were opened in 1897 on a site previously used as a convict prison. There are numerous brickyards, lime-kilns and flour-mills in the district neighbouring to Chatham, and the town carries on a large retail trade, in great measure owing to the presence of the garrison. Chatham was constituted a parliamentary borough by the Reform bill of 1832. Since 1918 the municipal boroughs of Chatham, Gillingham and Rochester combine to return two members. The town was incorporated in 1890. The borough includes the suburb (an ecclesiastical parish) of Luton, in which are the water-works of Chatham and district. Area of present borough of Chatham, 4,356 acres.

CHATHAM or MIRAMICHI, an incorporated town and port of entry in Northumberland county, New Brunswick, Canada, on the Miramichi river, 24m. from its mouth and on the Canadian National railway. Pop. (1931) 4,017. The town contains a Roman Catholic pro-cathedral, many saw-mills, pulp-mills, and establishments for curing and exporting fish. The lumber trade, fisheries and the manufacture of pulp are the chief industries.

CHATHAM, a city and port of entry of Ontario, Canada, and the capital of Kent county, 64m. S.W. of London and 11m. N. of Lake Erie, on the Thames river and the Canadian National, Canadian Pacific and Lake Erie and Huron railways. Pop. (1931) 14,569. It has steamboat connection with Detroit and the cities on Lakes Huron and Erie. It is situated in a rich agricultural and fruit-growing district, and carries on a large export trade. It contains a large wagon factory, planing and flour mills, manufactories of fanning mills, binder-twine, woven-wire goods, engines and windmills.

CHATHAM ISLANDS, a small group of islands in the Pacific ocean forming part of New Zealand, 536 m. due E. of Lyttleton, in South island, in about 44° S., 177° W. It consists of three islands, a large one called Whairikauri, or Chatham island, a small one, Rangihau, or Pitt island, and a third, Rangatira, or South-East island. There are also several rocky islets. Whairikauri, of which the highest point reaches about 1,000 ft., is remarkable for the number of small lakes it contains. Its form is irregular, being about 38 m. in length and 25 m. in extreme breadth,

with an area of 321 sq. miles. The geological structure (mainly volcanic rocks with schists and Tertiary limestone) indicate that the islands were once part of New Zealand. In general, the soil is extremely fertile, and where it is naturally drained a rich vegetation of fern and flax occurs. On the south-western side is Petre bay, on which, at the mouth of the river Mantagu, is Waitangi, the main settlement.

The islands were discovered in 1791 by Lieutenant W. R. Broughton (1762-1821) who gave them the name of Chatham from his boat. He called the natives Morioris or Maiorioris. In 1831 they were conquered by 800 Maoris who were landed from a European vessel. The natives were almost exterminated, and disease killed most of the remainder. Their language was akin to that of the Maoris of New Zealand, though they differed from them physically. Cattle and sheep are bred, and a small trade is carried on with whalers, which visit these seas. The chief export is wool, grown upon runs farmed both by Europeans and Morioris. There is naturally an import trade of European commodities. The population (1926) of the whole group was only 562 (268 Europeans and 294 Maoris and Morioris).

There are no indigenous mammals; the reptiles belong to New Zealand species. The birds—the largest factor in the fauna—have become very greatly reduced through the introduction of cats, dogs and pigs, as well as by constant destruction. The larger bell-bird is now scarce, the fruit-pigeon and the two endemic rails are extinct. The fossil avian forms are very important, especially from the point of view of the geographical distribution of species and the survival of the older forms in these remote corners. There have been discovered the remains of a species of swan belonging to the South American genus *Chenopsis*, and of the tuatara (*Hatteria*) lizard, the unique species of an ancient family now surviving only in New Zealand. One of the finest of the endemic flowering plants of the group is the boraginaceous "Chatham Island lily" (*Myositidium nobile*), and a gigantic forget-me-not, growing near the high-water mark on the shores. Dracophyllums, leucopogons, and arborescent ragworts are characteristic forms in the vegetation.

CHÂTILLON-SUR-SEINE, a town of eastern France, in the department of Côte-d'Or, on the Eastern and P.L.M. railways, 67 m. N.N.W. of Dijon. Pop. (1926), 4,279. It is situated on the upper Seine, which is here joined by the Douix; the source of which is much visited. Châtillon, an old feudal town, anciently consisted of two parts, Chaumont, belonging to the duchy of Burgundy, and Bourg, ruled by the bishop of Langres; they did not coalesce till the end of the 16th century. It was taken by the English in 1360 and by Louis XI. in 1475, during his struggle with Charles the Bold. Châtillon was one of the first cities to adhere to the League, but suffered severely from the oppression of its garrisons and governors. It is associated with the abortive conference of 1814 between the representatives of Napoleon and the Allies. The ruined 13th century castle of the dukes of Burgundy lies above the town. Near by stands the church of St. Vorle, begun in the 10th century, but with many additions; it contains a sculptured Holy Sepulchre of the 16th century and a number of frescoes. Marshal Marmont, duke of Ragusa was born at Châtillon in 1774, and built a château here. Its industries include iron-founding and the manufacture of agricultural machinery.

CHATSWORTH, a parish of Derbyshire, England, containing a famous seat belonging to the duke of Devonshire. Chatsworth House is situated close to the left bank of the river Derwent, 2½m. E.N.E. of Bakewell. It is Ionic in style, built foursquare, and enclosing a large open courtyard, with a fountain in the centre. In front, a beautiful stretch of lawn slopes gradually down to the riverside. The celebrated gardens are adorned with sculptures by Gabriel Cibber; the fountains are said to be surpassed only by those at Versailles. The great conservatory, unrivalled in Europe, which covered nearly an acre, was demolished in 1920. The house contains a famous library and a fine collection of pictures by Reynolds, Holbein, Dürer, Murillo, Jan van Eyck, Dolci, Veronese, Titian, Michelangelo, Leonardo da Vinci, Raffaele, Correggio; and sculptures by Canova, Thorwaldsen, Chantrey and R. J. Wyatt. Chatsworth Park is upwards of 11mi

in circuit. Beyond the river, and immediately opposite the house, stands the model village of Edensor, erected by order of the 6th duke. The parish church contains an old brass in memory of John Beaton, confidential servant to Mary, queen of Scots. In the churchyard are the graves of Lord Frederick Cavendish, murdered in 1882 in Phoenix Park, Dublin, and of Sir Joseph Paxton, the designer of the great conservatory.

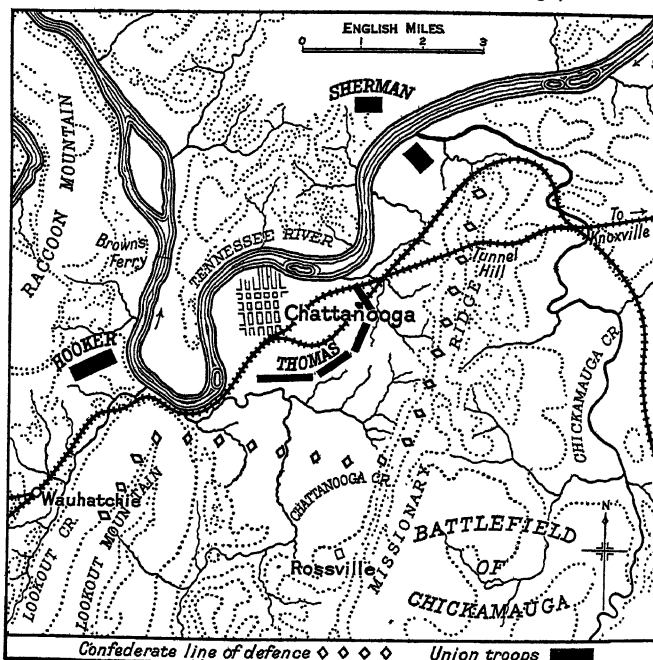

Chatsworth (*Chetsworde*, *Chetelsworde*, "the court of Chetel") took its name from Chetel, one of its Saxon owners. It was entrusted by the Conqueror to the custody of William Peverell. Chatsworth afterwards belonged for many generations to the family of Leech, and was purchased in the reign of Elizabeth by Sir William Cavendish, husband of the famous Bess of Hardwick. In 1557 he began to build Chatsworth House, and it was completed after his death by his widow, then countess of Shrewsbury. Here Mary, queen of Scots, spent several years of her imprisonment under the care of the earl of Shrewsbury. During the Civil War, Chatsworth was occupied as a fortress by both parties. It was pulled down, and the present house begun by William, 1st duke of Devonshire in 1688.

CHATTANOOGA, a city of Tennessee, U.S.A., on the Tennessee river, at the southern boundary of the State; a port of entry and the county seat of Hamilton county. It is at the intersection of Federal highways 11, 41 and 72; has a municipal airport, Marr Field; and is served by the Central of Georgia, the Nashville, Chattanooga and St. Louis, the Tennessee, Alabama and Georgia and the Southern railways, by river steamers and barges and by bus lines operating over a territory with a radius of 100 miles. The area is 16sq.m. The population in 1920 was 57,895 (32.6% negroes), and was 119,798 in 1930 Federal census. Within the metropolitan area of 25sq.m. a local census in 1927 counted 148,000. The city is picturesquely situated on Moccasin Bend, a sharp turn of the Tennessee, with Signal mountain to the north-west, Missionary ridge on the east, and to the south Lookout mountain (2,126ft.), which commands magnificent views in five States. Hydro-electric development on the Tennessee has provided practically unlimited power since 1913, and Chattanooga has become one of the most important manufacturing centres of the South, with 400 factories in or just outside the city, making over 1,300 articles. The annual output is valued at about \$160,000,000. Among the leading products are malleable iron and steel castings, clay and cast-iron pipes, fire hydrants, boilers, shovels, electrical insulator machinery, refrigerators, tapestry brick, paper, hosiery, oil-well and saw-mill and logging machinery, cedar chests, patent medicines, cement, gas ranges, smoothing irons, hay presses, pea-hulling machinery and portable asphalt-paving plants. In 1926 the city used 211,000,000 kw. hours of electric current. It consumes 1,200 tons of pig-iron per day. There is a large wholesale and retail business, and three insurance companies have their home offices here. Bank debts to individual accounts in 1926 amounted to \$581,737,000 and the assessed valuation of property was \$106,804,540. The educational institutions include the University of Chattanooga (Methodist Episcopal, established in 1866) and the Chattanooga college of Law. In the fine auditorium built as a memorial to the men who served in the World War, a season of grand opera is held every February, and weekly organ recitals are given on Sunday afternoons.

In 1817 missionaries came to the Cherokee Indians on the Chickamauga, 6m. E. of Chattanooga. In 1834 a Cherokee chief, John Ross, built a house (still standing) within the present limits of the city, and the place was long called Ross's Landing. It was incorporated as Chattanooga in 1851, and received a city charter in 1866. Since 1911 it has had a commission form of government. In 1860 the population was 2,545; in 1880, 12,892; in 1900, 30,154. The iron industry was well established even before the development of hydro-electric power, because of the proximity of coal-fields and iron mines. The city and its environs were the scene of important engagements in the Civil War, notably the battles of Chickamauga, on Sept. 18-20, 1863; and of Missionary Ridge and Lookout mountain ("the battle above the clouds"), on Nov. 24-25, 1863. The national cemetery in the city contains 14,248 graves (5,059 marked "unknown"),

and there is also a Confederate cemetery. Chickamauga battlefield, ten miles S. of Chattanooga, in Georgia, has been a national military park since 1895. In both the Spanish-American and the World War it was used for the mobilization and training of troops. Its 5,563 acres are dotted with over 2,000 monuments, and many others are scattered over Missionary Ridge, Lookout mountain and other historic spots. Ft. Oglethorpe, just north of the battlefield, is a regimental cavalry post.

Military.—From the end of September to November 24 the Army of the Cumberland was invested in Chattanooga by the Confederates, whose position lay along Missionary Ridge from its north end near the river towards Rossville, whence their entrenchments extended westwards to Lookout Mountain, which dominates the whole ground, the Tennessee running directly beneath it. Thus Rosecrans was confined to a semi-circle of low ground around Chattanooga itself, and his supplies had to make a long and difficult *détour* from Bridgeport, the main road being under fire from the Confederate position on Lookout and in the Wauhatchie valley adjacent. Bragg indeed expected that Rosecrans would be starved into retreat. But the Federals once more, and this time on a far larger scale, concentrated in the face of the enemy. The XI. and XII. corps from Virginia, under Hooker, were transferred by rail to reinforce Rosecrans; other troops were called up from the Mississippi, and on Oct. 16 the Federal government reconstituted the western armies under the supreme command of General Grant. The XV. corps of the Army of the Tennessee, under Sherman, was on the march from the Mississippi. Hooker's troops had already arrived when Grant reached Chattanooga on Oct. 23. The Army of the Cumberland was now under Thomas, Rosecrans having been recalled. The first action was fought at Brown's Ferry in the Wauhatchie valley, where Hooker executed with complete precision a plan for the revictualing of Chattanooga, established

PLAN OF THE BATTLE OF CHATTANOOGA, NOV. 23-25, 1863
In this battle of the American Civil War the armies of Hooker, Thomas and Sherman, under the supreme command of Gen. Grant, in successive assaults against the fortified heights of Lookout mountain and Missionary ridge won a decisive victory for the Union cause

himself near Wauhatchie on the 28th, and repulsed a determined attack on the same night. But Sherman was still far distant, and the Federal forces at Knoxville, against which a large detachment of Bragg's army under Longstreet was now sent, were in grave danger. Grant waited for Sherman's four divisions, but prepared everything for battle in the meantime. His plan was that Thomas, in the Chattanooga lines, should contain the Confederate centre on Missionary Ridge, while Hooker on the right, at Wauhatchie, was to attack Lookout Mountain, and Sherman, farther up the river, was to carry out the decisive attack against Bragg's extreme

right wing at the end of Missionary Ridge. The last marches of the XV. corps were delayed by stormy weather, Bragg reinforced Longstreet, and telegraphic communication between Grant and the Federals at Knoxville had already ceased. But Grant would not move forward without Sherman, and the battle of Chattanooga was fought more than two months after Chickamauga. On Nov. 23 a forward move of Thomas's army, intended as a demonstration, developed into a serious and successful action, whereby the first line of the Confederate centre was driven in for some distance. Bragg was now much weakened by successive detachments having been sent to Knoxville, and on the 24th the real battle began. Sherman's corps was gradually brought over the river near the mouth of Chickamauga Creek and formed up on the east side.

The attack began at 1 P.M. and was locally a complete success. The heights attacked were in Sherman's hands, and fortified against counter-attack, before nightfall. Hooker in the meanwhile had fought the "Battle above the Clouds" on the steep face of Lookout Mountain, and though opposed by an equal force of Confederates, had completely driven the enemy from the mountain. The 24th then had been a day of success for the Federals, and the decisive attack of the three armies in concert was to take place on the 25th. But the maps deceived Grant and Sherman as they had previously deceived Rosecrans. Sherman had captured, not the north point of Missionary Ridge, but a detached hill, and a new and more serious action had to be fought for the possession of Tunnel Hill, where Bragg's right now lay strongly entrenched. The Confederates used every effort to hold the position and all Sherman's efforts were made in vain. Hooker, who was moving on Rossville, had not progressed far, and Bragg was still free to reinforce his right. Grant therefore directed Thomas to move forward on the centre to relieve the pressure on Sherman. The Army of the Cumberland was, after all, to strike the decisive blow. About 3.30 P.M. the centre advanced on the Confederate's trenches at the foot of Missionary Ridge. These were carried at the first rush, and the troops were ordered to lie down and await orders. Then occurred one of the most dramatic episodes of the war. Suddenly, and without orders either from Grant or the officers at the front, the whole line of the Army of the Cumberland rose and rushed up the ridge. Two successive lines of entrenchments were carried at once. In a short time the crest was stormed, and after a last attempt at resistance the enemy's centre fled in the wildest confusion. The pursuit was pressed home by the divisional generals, notably by Sheridan. Hooker now advanced in earnest on Rossville, and by nightfall the whole Confederate army, except the troops on Tunnel Hill, was retreating in disorder. These too were withdrawn in the night, and the victory of the Federals was complete. Bragg lost 8,684 men killed, wounded and prisoners out of perhaps 34,000 men engaged; Grant, with 60,000 men, lost about 6,000.

CHATTEL, a term used in English law as equivalent to "personal property," that is, property which, on the death of the owner, devolves on his executor or administrator to be distributed (unless disposed of by will) among the next of kin according to the Statutes of Distributions. Chattels are divided into *chattels real* and *chattels personal*. Chattels real are those interests in land for which no "real action" (see ACTION) lies; estates which are less than freehold (estates for years, at will, or by sufferance) are chattels real. Chattels personal are such things as belong immediately to the person of the owner, and for which, if they are injuriously withheld from him, he has no remedy other than by a personal action. Chattels personal are divided into *choses in possession* and *choses in action* (see CHOSE).

CHATTEL MORTGAGE, a transaction by which an owner of personal property transfers the property to a creditor for the purpose of securing payment of the debt. The chattel mortgage differs from a pledge in that the latter requires transfer of possession and control of the goods to the creditor, whereas in the typical chattel mortgage full possession and use of the goods remain in the mortgagor. And precisely here lie both the great economic advantage and the social danger of the device. For, having possession, use and control, the mortgagor retains the economic use of goods which he is vastly better able to utilize than is his lender;

indeed, out of such use he may realize the wherewithal to pay off the very debt secured by the mortgage. So in the case of a chattel mortgage on crops to be sown or grown, the advances of the country banker are intended to finance the growing of those crops, and will normally be repaid out of its sale. And so with live stock mortgages and mortgages on the equipment of a factory, of a small plant, etc. On the other hand, the continued and unrestricted possession of the goods by the mortgagor is likely to mislead his other creditors, present or prospective, into the belief that his assets are greater than they are; and in the event of trouble, the mortgagee's prior claim, if sustained, may come in to cut them off from any possibility of realizing their debts. Out of this double need has arisen legislation in all American States except Pennsylvania (which does not recognize the chattel mortgage) limiting the validity of the transaction unless the mortgagee takes possession, or unless the mortgage instrument is filed for public information in some prescribed public office. But the details of the legislation are amazingly diverse. In some States the filing is required to be in the county where the mortgagor resides; in others, in that where the goods are located, in still others, in both. In some States possession or filing must occur at once, to be effective; in others, within a fixed period, such as ten days; in still others it is effective as soon as it occurs, whenever that may be. Everywhere, persons purchasing the goods from the mortgagor in possession take free of the mortgage if it has not been filed, and if they are ignorant of it. Everywhere, some of the mortgagor's creditors can disregard the mortgage, if it remains unfiled; but the precise classes of creditors protected vary widely. It may be safely stated, however, that a mortgagee who does not comply with the statute nowhere acquires a satisfactory security.

The requirements of form are equally diverse. The form of apparently outright bill of sale (*q.v.*) is permissible, but not widely used, to evidence chattel mortgages in the United States. In States where no form is required, save a paper signed by the mortgagor, the object is to allow business to be done simply and quickly. But some States attempt to avoid fraudulent practices of mortgagees by requiring the mortgagor to receive, and give a receipt for, a copy of the mortgage; the purpose is to make fraudulent alteration easy to detect. Others fear dishonest practices of mortgagors, and require witnesses or formal acknowledgment to make the document valid. Here the attempt is, in part, to prevent the mortgagor from later denying that he gave the mortgage. Others require, in addition, affidavits by the mortgagor, or by the mortgagee, or by both, that the debt secured is in truth owed, and the transaction *bona fide*. This last requirement arises out of the apparently not uncommon practice of debtors—especially merchants—when approaching insolvency, of creating fictitious debts to their friends, and attempting to divert their assets by colourable mortgages to secure such debts. And because of a similar fear of creditors being misled, a mortgage on a merchant's floating stock in trade has been hedged about by the courts with so many restrictions as to make it worthless as a continuing security to-day. That chattel mortgages are regarded—at least where merchants are the mortgagors—as signs of serious financial difficulty, sufficient to cause suspension of credit, is partly due to this fact, partly to their evil odour because of much attempted fraudulent use, and partly to the fact that in open-credit selling the sellers properly insist on the stock of goods continuing unencumbered: they have supplied the goods; they do not want those same goods to be diverted to paying debts to others.

Almost everywhere a chattel mortgage is good between mortgagor and mortgagee, despite non-compliance with such formalities or with the filing provisions of the local statute. The mortgagee can take possession and foreclose on default in payment of the debt, or in any other of the terms of the transaction—common requirements being that the mortgagor shall keep the goods on the premises, shall not attempt to sell them, nor suffer attachment of the goods by other creditors, and so on. The risk of loss by fire or theft lies, always, on the mortgagor; and often, too, he is required by the mortgage to keep the goods insured for the mortgagee's benefit.

Chattel mortgages are in wide use. Crop mortgages are a major

basis for financing current farm operations throughout the country. The same is true of live stock raising; save that here the mortgages are commonly taken in the first instance by specialized mortgage companies rather than by banks or local merchants. The wide-spread instalment selling business makes considerable use of the device, though more of the conditional sale (see *HIRE-PURCHASE AGREEMENT*). In the shape of mortgages on articles of personal use such as automobiles, and on household furniture, chattel mortgages underlie many of the small consumption loans of needy borrowers—often with serious abuses. And they are becoming increasingly important in corporate mortgage-bond issues, since a mortgage on plant is obviously seriously impaired unless it can be made to cover the plant's equipment as well. In this last field serious discrepancy is beginning to be felt between the real estate portion of the security, as to which recording, once effected, is good forever, and the chattel portion, as to which periodical re-filing is necessary. Finally, the chattel mortgage, in the peculiar form of the trust receipt (*q.v.*), is used in the financing of imports, and of the sale of automobiles. In this form—an exception carved by the courts out of general statutes—it is good as against the mortgagor's creditors irrespective of filing or possession; but not as against purchasers without notice.

In the United States the chattel mortgage takes the place of the bill of sale, the latter term being there applied to a signed document describing goods and evidencing their sale, which a seller gives to a buyer who for some reason requires evidence of his ownership. Of late years the prevalence of automobile thefts has led generally to legislation requiring a bill of sale to be made out in the case of sales of second hand cars, and filed with the licensing authorities of the State. (K. N. L.)

CHATTERER, the general name applied to the members of two families of birds. The true chatterers are the Ampelidae, the best-known species of which are the waxwing (*q.v.*) and the American cedar-bird. The South American chatterers are the Cotingidae, woodland birds, feeding mainly on fruit; the best known are the cocks-of-the-rock, umbrella and bell-birds (*qq.v.*).

CHATTERIS, urban district and market town in the Isle of Ely, Cambridgeshire, England, 25½ m. N. by W. of Cambridge by the L.N.E.R. Pop. (1931) 5,153. The church of St. Peter is principally Decorated; and there are fragments of a Benedictine convent founded in the 10th century and rebuilt after fire in the early 14th. To the north runs the great Forty-foot Drain, also called Vermuyden's, after the Dutch engineer, whose name is associated with the fen drainage works of the mid 17th century.

CHATTERJI, BANKIM CHANDRA (BANKIMACHANDRA CHATTĀRADH-YĀYA) (1838-1894), Indian novelist, was born in the district of the Twenty-four Parganas in Bengal on June 27, 1838, and was by caste a Brahman. He was educated at the Hugli college, at the Presidency college in Calcutta, and at Calcutta university, where he was the first to take the degree of B.A. (1858). He entered the Indian civil service, and served as deputy magistrate in various districts of Bengal, his official services being recognized, on his retirement in 1891, by the title of rai bahadur and the C.I.E. He died on April 8, 1894.

Bankim Chandra was beyond question the greatest novelist of India during the 19th century, whether judged by the amount and quality of his writings, or by the influence which they have continued to exercise. He created in India a school of fiction on the European model. His novels include *Durges-Nandini*, *Kapala-Kundala*, *Mrinalini*, and *Bisha-Brikha*. His outstanding work however is the *Ananda Math*, a story of the Sannyasi rebellion of 1772. The rebels gained a crushing victory over the British and Mohammedan forces. This success was, however, not followed up as a mysterious "physician," speaking as a divinely-inspired prophet, advised Satyananda to abandon further resistance; as, for the time, British rule was the only alternative to Mohammedan oppression. This book contains the famous song *Bande Mataram*.

Although the *Bande Mataram* was not used during Chatterji's

life time as a party war-cry, it became, during the agitation which followed the partition of Bengal, the recognized patriotic song of the revolutionary party. The words *Bande Mataram*, "Hail to thee; Mother" are usually held to be an invocation to Kali, the goddess of death and destruction. The Sanyassi rebels are represented as having erected, in addition to the dark image of Kali "The Mother who has been," a white marble statue of the "Mother that shall be": the poet sings the praise of the "Mother"

as Lachmi bowered in the flower
that in the water grows,

but he also praises her as "Durga, bearing ten weapons." Other passages, too, are susceptible of revolutionary interpretation. Whatever Chatterji's original intention (it is sometimes held that it is merely an invocation of the Motherland) the story of the Sanyassis, the ingenious language and its stirring air, the *Mallarkawali-Tal*, all have a strong appeal to the Hindu mind and the *Bande Mataram* has become a powerful influence in political agitation and the accepted hymn of the extremist party.

In his earlier years Bankim Chandra served his apprenticeship in literature under Iswar Chandra Vidyasagar, the chief poet and satirist of Bengal during the earlier half of the 19th century. Bankim Chandra's friend and colleague, Dina Bandhu Mitra, was virtually the founder of the modern Bengali drama. Among the younger men who venerated Bankim Chandra, and benefited by his example and advice, may be mentioned two distinguished poets, Nalein Chandra Sen and Rabindranath Tagore.

CHATTERTON, THOMAS (1752-1770), English poet, was born at Bristol on Nov. 20, 1752, three months after the death of his father, who had been master of the Pile street free school, at Bristol. In 1760 Chatterton was sent to the Colston free school where he stayed for eight years. But this Bristol blue-coat school had little share in the education of its marvellous pupil. The office of sexton at the church St. Mary Redcliffe had been held for nearly two centuries by the Chatterton family, and under the guidance of his uncle, the child found his favourite haunt in the beautiful old church, deriving a fresh interest, when he was able to read, in certain quaint old chests, where parchment deeds, old as the Wars of the Roses, lay unheeded and forgotten. In 1763 a beautiful cross of curious workmanship, which had adorned the churchyard of St. Mary Redcliffe for upwards of three centuries, was destroyed by a churchwarden, and the boy sent to the local journal on Jan. 7, 1764, a clever satire on the parish vandal. His delight was to lock himself in a little attic, where, with books, cherished parchments, saved from the loot of the muniment room of St. Mary Redcliffe, and drawing materials, he lived in thought with his 15th century heroes and heroines. The first of his literary mystifications, the duologue of "Elinoure and Juga," was written before he was twelve years old, and he showed it to the usher at Colston's hospital, T. Phillips, as the work of a 15th century poet.

His "Rowleian" jargon appears to have been chiefly the result of the study of John Kersey's *Dictionarium Anglo-Britannicum*, and Prof. W. W. Skeat seems to think his knowledge even of Chaucer was very slight. He had already conceived the romance of Thomas Rowley, an imaginary monk of the 15th century, and lived for the most part in an ideal world of his own, in that elder time when Edward IV. was England's king, and Master William Canynge—familiar to him among the recumbent effigies in Redcliffe church—still ruled in Bristol's civic chair. Canynge is represented as an enlightened patron of literature, and Rowley's dramatic interludes were written for performance at his house. In order to escape a marriage urged by the king, Canynge retired to the college of Westbury in Gloucestershire, where he enjoyed the society of Rowley, and eventually became dean of the institution. The literary masquerade which thus constituted the life-dream of the boy was wrought out by him in fragments of prose and verse into a coherent romance, until the credulous scholars and antiquaries of his day were persuaded into the belief that there had lain in the parish chest of Redcliffe church for upwards of three centuries, a collection of mss. of rare merit, the work of Thomas Rowley, an unknown priest of Bristol in the days

of Henry VI., and his poet laureate, John Lydgate.

Among the Bristol patrons of Chatterton were two pewterers, George Catcott and his partner Henry Burgum. Catcott was one of the most zealous believers in Rowley, and continued to collect his reputed writings long after the death of their real author. On Burgum, who had risen in life by his own exertions, the blue-coat boy palmed off the de Bergham pedigree, and other equally apocryphal evidences of the pewterer's descent from an ancestry old as the Norman Conquest. The de Bergham quartering, blazoned on a piece of parchment doubtless recovered from the Redcliffe muniment chest, was itself supposed to have lain for centuries in that ancient depository. The pedigree was professedly collected by Chatterton from original records, including "The Rowley mss." The pedigree still exists in Chatterton's own handwriting, copied into a book in which he had previously transcribed portions of antique verse, under the title of "Poems by Thomas Rowley, priest of St. John's, in the city of Bristol"; and in one of these, "The Tournament," Syrr Johan de Berghamme plays a conspicuous part. The ennobled pewterer rewarded Chatterton with five shillings, and was satirized for this valuation of a noble pedigree in some of Chatterton's latest verse.

On July 1, 1767, Chatterton was transferred to the office of John Lambert, attorney, to whom he was bound apprentice as a clerk. There he found leisure for his own favourite pursuits. An ancient stone bridge on the Avon, built in the reign of Henry II., had been displaced by a new bridge opened in 1768. Shortly afterwards the editor of *Felix Farley's Journal* received from a correspondent, signing himself *Dunelmus Bristolensis*, a "description of the mayor's first passing over the old bridge," professedly derived from an ancient ms. The original manuscript is now preserved in the British Museum, along with other Chatterton mss., most of which were ultimately incorporated by William Barrett in his *History and Antiquities of the city of Bristol*, published nearly 20 years after the poet's death. It was at this time that the definite story made its appearance—over which critics and antiquaries wrangled for nearly a century—of numerous ancient poems and other mss. taken by the elder Chatterton from a coffer in the muniment room of Redcliffe church, and transcribed, and so rescued from oblivion, by his son. The pieces include the "Bristowe Tragedie, or the Dethe of Syr Charles Bawdin," a ballad celebrating the death of the Lancastrian knight, Charles Baldwin; "Ælla," a "Tragycal Enterlude," as Chatterton styles it, but in reality a dramatic poem of sustained power; "Goddwyn," a dramatic fragment; "Tournament," "Battle of Hastings," "The Parliament of Sprites," "Balade of Charitie," with numerous shorter pieces, forming altogether a volume of poetry, the rare merit of which is indisputable, wholly apart from the fact that it was the production of a mere boy.

In Dec., 1768, in his seventeenth year, he wrote to Dodsley, the London publisher, offering to procure for him "copies of several ancient poems, and an interlude, perhaps the oldest dramatic piece extant, wrote by one Rowley, a priest in Bristol, who lived in the reigns of Henry VI. and Edward IV." To this letter, as well as to another letter enclosing an extract from the tragedy of "Ælla," no answer appears to have been returned. Chatterton then bethought him of Horace Walpole, who not only indulged in a mediæval renaissance of his own, but was the reputed author of a spurious antique in the *Castle of Otranto*. He wrote to him offering him a document entitled "The Ryse of Peyncteyne yn Englande, wroten by T. Rowleie, 1469, for Mastre Canynge," accompanied by notes which included specimens of Rowley's poetry. To this Walpole replied with courteous acknowledgments. He characterized the verses as "wonderful for their harmony and spirit," and added, "Give me leave to ask you where Rowley's poems are to be had? I should not be sorry to print them; or at least a specimen of them, if they have never been printed." Chatterton replied, enclosing additional specimens of antique verse, and telling Walpole that he was the son of a poor widow, and clerk to an attorney, and he hinted a wish that he might help him to some more congenial occupation. Walpole's

manner underwent an abrupt change. The specimens of verse had been submitted to his friends, Gray and Mason, and pronounced modern. He now coldly advised the boy to stick to the attorney's office, and "when he should have made a fortune," he might betake himself to more favourite studies. Chatterton had to write three times before he recovered his mss. Walpole has been loaded with more than his just share of responsibility for the fate of the unhappy poet, of whom he admitted when too late, "I do not believe there ever existed so masterly a genius."

Chatterton now began to contribute to the *Town and County Magazine* and other London periodicals. Assuming the vein of Junius—then in the full blaze of his triumph—he turned his pen against the duke of Grafton, the earl of Bute, and the princess of Wales. He had just despatched one of his political diatribes to the *Middlesex Journal*, when he sat down on Easter Eve, April 17, 1770, and penned his "Last Will and Testament," a strange satirical compound of jest and earnest, in which he intimated his intention of putting an end to his life the following evening. Among his satirical bequests, such as his "humility" to the Rev. Mr. Camplin, his "religion" to Dean Barton, and his "modesty" along with his "prosody and grammar" to Mr. Burgum, he leaves "to Bristol all his spirit and disinterestedness, parcels of goods unknown on its quay since the days of Canynge and Rowley." In more genuine earnestness he recalls the name of Michael Clayfield, a friend to whom he owed intelligent sympathy. The will was probably purposely prepared in order to frighten his master into letting him go. Lambert cancelled his indentures, his friends made him up a purse, and on the 25th or 26th of the month he arrived in London.

Chatterton was already known to the readers of the *Middlesex Journal* as a rival of Junius, under the *nom de plume* of Decimus. He had also been a contributor to Hamilton's *Town and County Magazine*, and speedily found access to the *Freeholder's Magazine*, another political miscellany strong for Wilkes and liberty. Wilkes himself had noted his trenchant style, "and expressed a desire to know the author"; and Lord Mayor Beckford graciously acknowledged a political address of his, and greeted him "as politely as a citizen could." But of actual money he received little. He was extremely abstemious, but his diligence was great, and his versatility wonderful. He could assume the style of Junius or Smollett, reproduce the satiric bitterness of Churchill, parody Macpherson's Ossian, or write in the manner of Pope, or with the polished grace of Gray and Collins. He wrote political letters, eclogues, lyrics, operas and satires, both in prose and verse. In June, 1770—after Chatterton had been some nine weeks in London—he removed from Shoreditch, where he had hitherto lodged with a relative, to an attic in Brook street, Holborn, where, for the first time, he enjoyed uninterrupted solitude. The romance of his earlier years revived, and he transcribed from an imaginary parchment of the old priest Rowley his "Excelente Balade of Charitie." This fine poem, perversely disguised in archaic language, he sent to the editor of the *Town and County Magazine*, and had it rejected.

The high hopes of the sanguine boy had begun to fade. He had not yet completed his second month in London, and already failure and starvation stared him in the face. The note of his actual receipts, found in his pocket-book after his death, shows that Hamilton, Fell and other editors who had been so liberal in flattery had paid him at the rate of a shilling for an article, and somewhat less than eightpence each for his songs; while much which had been accepted was held in reserve, and still unpaid for. The beginning of a new month revealed to him the indefinite postponement of the publication and payment of his work. He had wished, according to his foster-mother, to study medicine with Barrett; in his desperation he now reverted to this, and wrote to Barrett for a letter to help him to an opening as a surgeon's assistant on board an African trader. He appealed also to Mr. Catcott to forward his plan, but in vain. On Aug. 24, 1770, he retired for the last time to his attic in Brook street, carrying with him the arsenic which he there drank, after tearing into fragments whatever literary remains were at hand.

He was only seventeen years and nine months old; but the best of his numerous productions, both in prose and verse, require no allowance to be made for the immature years of their author. He pictures Lydgate, the monk of Bury St. Edmund's, challenging Rowley to a trial at versmaking, and under cover of this fiction, produces his "Songe of Ælla," a piece of rare lyrical beauty, worthy of comparison with any antique or modern production of its class. Again, in his "Tragedy of Goddwyn," of which only a fragment has been preserved, the "Ode to Liberty," with which it abruptly closes, may claim a place among the finest martial lyrics in the language. The death of Chatterton attracted little notice at the time; for the few who then entertained any appreciative estimate of the Rowley poems regarded him as their mere transcriber. He was interred in a burying-ground attached to Shoe Lane Workhouse. A monument has since been erected to his memory in Redcliffe churchyard, Bristol, with the appropriate inscription, borrowed from his "Will," and so supplied by the poet's own pen—"To the memory of Thomas Chatterton. Reader! judge not. If thou art a Christian, believe that he shall be judged by a Superior Power. To that Power only is he now answerable."

BIBLIOGRAPHY.—*Poems supposed to have been written at Bristol by Thomas Rowley and others, in the Fifteenth Century* (1777) was edited by Thomas Tyrwhitt; Thomas Warton, in his *History of English Poetry* (1778); vol. ii., section viii., gives Rowley a place among the 15th century poets; but neither of these critics believed in the antiquity of the poems. In 1782 a new edition of Rowley's poems appeared, with a "Commentary, in which the antiquity of them is considered and defended," by Jeremiah Milles, dean of Exeter. The controversy which raged round the Rowley poems is discussed in A. Kippis *Biographia Britannica* (vol. iv., 1789), where there is a detailed account by G. Gregory of Chatterton's life (pp. 573-619). This was reprinted in the edition (1803) of Chatterton's *Works* by R. Southey and J. Cottle, published for the benefit of the poet's sister. The neglected condition of the study of earlier English in the 18th century alone accounts for the temporary success of Chatterton's mystification. It has long been agreed that Chatterton was solely responsible for the Rowley Poems, but the language and style are analysed in confirmation of this view by Prof. W. W. Skeat in an introductory essay prefaced to vol. ii. of *The Poetical Works of Thomas Chatterton* (1871) in the "Aldine Edition of the British Poets." This, which is the most convenient edition, also contains a memoir of the poet by Edward Bell. The spelling of the Rowley poems is there modernized, and many of the archaic words are replaced by modern equivalents provided in many cases from Chatterton's own notes, the theory being that Chatterton usually composed in modern English, and inserted his peculiar words and his complicated orthography afterwards. See also H. B. Forman, *Thomas Chatterton and his latest Editor* (1874). The Chatterton mss., originally in the possession of William Barrett of Bristol, were left by his heir to the British Museum in 1800. Others are preserved in the Bristol library.

Chatterton's genius and his tragic death are commemorated by Shelley in *Adonais*, by Wordsworth in "Resolution and Independence," by Coleridge in "A Monody on the Death of Chatterton," by D. G. Rossetti in "Five English Poets"; John Keats inscribed *Endymion* "to the memory of Thomas Chatterton." Alfred de Vigny's drama of *Chatterton* gives an altogether fictitious account of the poet. Sir Herbert Croft, in his *Love and Madness*, interpolated a long and valuable account of Chatterton, giving many of the poet's letters, and much information obtained from his family and friends (pp. 125-244, letter li.). There is a valuable collection of "Chattertoniana" in the British Museum, consisting of separate works by Chatterton, newspaper cuttings, articles, dealing with the Rowley controversy and other subjects, with ms. notes by Joseph Haslewood, and several autograph letters. F. A. Hyatt and W. Bazeley, *Chattertoniana* (Gloucester, 1914), a catalogue of printed matter.

Among biographies of Chatterton may be mentioned Daniel Wilson, *Chatterton: A Biographical Study* (1869); D. Masson, *Chatterton: A Biography* (1899); Helene Richter, "Thomas Chatterton" (1900), in *Wiener Beiträge zur engl. Philologie*; C. E. Russell, *Chatterton*, (1909); J. H. Ingram, *The True Chatterton* (1910); Sir E. Clarke, *New Lights on Chatterton* (1916), a paper read before the Bibliographical Society, London.

CHATTI, an ancient German tribe inhabiting the upper reaches of the rivers Weser, Eder, Fulda and Werra, a district approximately corresponding to Hesse-Cassel, though probably somewhat more extensive. They frequently came into conflict with the Romans during the early years of the 1st century A.D. Eventually they formed a portion of the Franks and were incorporated in the kingdom of Clovis at the beginning of the 6th century.

See Tacitus, *Annals*, i., ii., xi., xii. and xiii.; *Germania*, 30-31.

CHAUCER, GEOFFREY (1340?-1400), English poet, was born, about 1340, of a family which had been settled in London for at least two generations, but probably came from the eastern counties. His father, John Chaucer, lived at one time in Cordwainer street, the quarter of the shoemakers, with which the name Chaucer (a French form of the Latin *Calcearius*) connects the family. But John Chaucer, his father Robert, and a step-father Richard, were vintners, and Robert and John held offices connected with the customs on wine. Geoffrey was probably born at Thames street, where his father is found living somewhat later, with a wife, Agnes, niece of Hamo de Compton, probably the poet's mother. In 1357 Geoffrey is found, apparently as a lad, in the service of Elizabeth, countess of Ulster, wife of Lionel, duke of Clarence. In 1359 he went to the war in France and is heard of at Retters, i.e., Rethel, near Reims, and as being taken prisoner. The king contributed £16 to his ransom and it is probable that after his return he was for some time at the Inner Temple, where, at a considerable cost, an education was given likely to help suitable men for civil employment under the Crown. By June 20, 1367, he had been long enough in the king's service to be granted a pension of 20 marks, probably in connection with his marriage with a Philippa, one of two daughters of Sir Payne Roet, who in the previous September had been granted a pension of ten marks for her services to the queen as one of her *domicellae*. Philippa's sister, Katherine, after the death of her husband, Sir Hugh de Swynford, in 1372, became governess to John of Gaunt's children, and subsequently his mistress, and (in 1396) his wife. The marriage with Philippa thus helps to account for the favour subsequently shown to Chaucer by John of Gaunt.

In the grant of his pension Chaucer is called "dilectus vallectus noster," our beloved yeoman; before the end of 1368 he had risen to one of the king's esquires. In September of the following year John of Gaunt's wife, the duchess Blanche, died at the age of 29, and Chaucer wrote in her honour *The Book of the Duchesse*, a poem of 1,334 lines in octosyllabic couplets. In June 1370 he went abroad on the king's service, on an unknown errand, returning probably some time before Michaelmas. On Dec. 1, 1372, he started, with an advance of 100 marks in his pocket, for Italy, as one of three commissioners to treat with the Genoese as to an English port where they might have special facilities for trade. His accounts, delivered on May 23, 1373, show that he had also visited Florence on the king's business, and he possibly went also to Padua and there made the acquaintance of Petrarch.

In the second quarter of 1374, Chaucer lived in a whirl of prosperity. On April 23 the king granted him a pitcher of wine daily, subsequently commuted for an annuity of 20 marks. From John of Gaunt, who in Aug. 1372 had granted Philippa Chaucer £10 a year, he himself now received (June 13) a like annuity. On June 8 he was appointed (with a salary of £10 and an annual gratuity of £6 13s.4d.) comptroller of the Custom and Subsidy of Wools, Hides and Woodfells and also of the Petty Customs of Wine in the Port of London. Probably in anticipation of this appointment he had taken, on May 10, a lease for life from the city of London of the dwelling-house above the gate of Aldgate, and here he lived for the next 12 years. In 1375-76 two large windfalls came to him, the first being two wardships of Kentish heirs, one of whom paid him £104, the second a grant of £71 4s.6d. the value of some confiscated wool. In Dec. 1376 he was sent abroad on the king's service in the retinue of Sir John Burley; in Feb. 1377 he was sent to Paris and Montreuil in connection probably with the peace negotiations between England and France, and at the end of April (after a reward of £20 for his good services) he was again despatched to France. It is generally considered that this diplomatic period of his life was unproductive in poetry.

On the accession of Richard II., Chaucer was confirmed in his offices and pensions. In Jan. 1378 he seems to have been in France in connection with a proposed marriage between Richard and the daughter of the French king; and on May 28 of the same year he was sent (his last diplomatic journey) with Sir Edward de Berkeley to the lord of Milan and Sir John Hawkwood to treat for help in the king's wars, returning on Sept. 19. In April 1382 a new comptrollership, that of the petty customs in the Port of London,

was given him, and shortly after he was allowed to exercise it by deputy, a similar licence being given him in Feb. 1385, at the instance of the earl of Oxford, as regards the comptrollership of wool. In Oct. 1385 he was made a justice of the peace for Kent. In Feb. 1386 we catch a glimpse of his wife, Philippa, being admitted to the fraternity of Lincoln cathedral in the company of Henry, earl of Derby (afterwards Henry IV.), Sir Thomas de Swynford and other distinguished persons. In Aug. 1386 he was elected one of the two knights of the shire for Kent, and with this dignity (one not much appreciated in those days) his good fortune reached its climax. In December he was superseded in both his comptrollerships, probably as a result of the absence of his patron, John of Gaunt, in Spain, and the supremacy of the duke of Gloucester. In the following year the cessation of Philippa's pension suggests that she died between midsummer and Michaelmas. In May 1388 Chaucer surrendered to the king his two pensions of 20 marks each, and they were regranted at his request to one John Scalby, an unusual transaction, pointing to a pressing need for ready money.

In July 1389, after John of Gaunt had returned to England, and the king had taken the government into his own hands, Chaucer was appointed clerk of works at various royal palaces at a salary of two shillings a day. To this post was subsequently added the charge of some repairs at St. George's chapel, Windsor. He was also made a commissioner to maintain the banks of the Thames between Woolwich and Greenwich, and was given by the earl of March (grandson of Lionel, duke of Clarence, his first patron) a sub-forestership at North Petherton, Devon; obviously a sinecure. While on the king's business, in Sept. 1390, Chaucer was twice robbed by highwaymen, losing £20 of the king's money. In June 1391 he was superseded as clerk of the works, and seems to have suffered another spell of misfortune, of which the first alleviation came in Jan. 1393, when the king made him a gift of £10. In Feb. 1394 he was granted a new pension of £20. In 1397 he received from King Richard a grant of a butt of wine yearly. For this he appears to have asked in terms that suggested poverty, and in May 1398 he obtained letters of protection against his creditors. On the accession of Henry IV. a new pension of 40 marks was granted him (Oct. 13, 1399) and Richard II.'s grants were formally confirmed. Though no instalment of the new pension was paid, on the strength of his expectations (Dec. 24, 1399), Chaucer leased a tenement in the garden of St. Mary's chapel, Westminster, and it was probably here that he died on the following Oct. 25. He was buried in Westminster Abbey, and his tomb became the nucleus of what is now known as Poets' Corner.

The portrait of Chaucer, which the affection of his disciple, Thomas Hoccleve, caused to be painted in a copy of the latter's *Regement of Princes* (now Harleian ms. 4,866 in the British Museum), shows him an old man with white hair; he has a fresh complexion, grey eyes, a straight nose, a grey moustache and a small double-pointed beard. His dress and hood are black, and he carries in his hands a string of beads.

Works.—Henry IV.'s promise of an additional pension was doubtless elicited by the *Compleynt to his Purs*, in the envoy to which Chaucer addresses him as the "conquerour of Brutes Albioun." Thus within the last year of his life the poet was still writing. Nevertheless, as early as 1393-94, in lines to his friend Scogan, he had written as if his day for poetry were past, and it seems probable that his longer poems were all composed before this date. In the preceding 15—or, if another view be taken, 20—years, his literary activity was very great, and with the aid of the lists of his works which he gives in the *Legende of Good Women* (lines 414-431), and the talk on the road which precedes the "Man of Lawe's Tale" (*Canterbury Tales*, B. 46-76), the order in which his main works were written can be traced with approximate certainty.

The development of Chaucer's genius has been attractively summed up as comprised in three stages, French, Italian and English, and there is a rough approximation to the truth in this formula, since his earliest poems are translated from the French or based on French models, and the two great works of his middle period are borrowed from the Italian, while his latest stories have

no such obvious and direct originals, and in their humour and freedom anticipate the typically English temper of Henry Fielding. But Chaucer's indebtedness to French poetry was no passing phase. He knew the *Roman de la rose* as modern English poets know Shakespeare, and the full extent of his debt to his French contemporaries, not merely in 1369, but in 1385, and in 1393 (the dates are approximate), has only gradually been discovered. To this continuing French influence it was his good fortune to add lessons in plot and construction derived from Boccaccio's *Filosttrato* and *Teseide*, as well as some glimpses of the higher art of the *Divina Commedia*. He shows acquaintance also with one of Petrarch's sonnets. His study of Italian models was thus an episode of unique importance in his literary life, but before it began he had already been making his own artistic experiments, and it is noteworthy that while he learnt much from Boccaccio he improved on his originals as he translated them. Doubtless his busy life in the service of the Crown had taught him self-confidence, and he uses his Italian models in his own way and with the most triumphant and assured success. When he had no more Italian poems to adapt he had learnt his lesson. In his "English" period we find him taking what might be little more than an anecdote and lending it body and life and colour with a skill never surpassed.

Early Period.—The most direct example of Chaucer's French studies is his translation of *Le Roman de la rose*, a poem written in some 4,000 lines by Guillaume Lorris about 1237 and extended to over 22,000 by Jean Clopinel, better known as Jean de Meun, 40 years later. We know from Chaucer himself that he translated this poem, and the extant English fragment of 7,698 lines was generally assigned to him from 1532, when it was first printed, till its authorship was challenged in the early years of the Chaucer Society. The ground of this challenge was its wide divergence from Chaucer's practice in his undoubtedly genuine works as to certain niceties of rhyme, notable as to not rhyming words ending in -y with others ending -ye. It was subsequently contended, however, that the whole fragment is divisible linguistically into three portions, of which the first and second end respectively at lines 1,705 and 5,810, and that in the first of these three sections the variations from Chaucer's accepted practice are insignificant. Lines 1-1,705 have therefore been provisionally accepted as Chaucer's and the other two fragments as the work of unknown translators which somehow came to be pieced together. A rival theory proposed by Dr. Brusendorf assigns the whole fragment to a professional reciter writing down what he remembered of the parts of Chaucer's translation he was accustomed to recite, and varying when his memory failed.

While our knowledge of Chaucer's *Romaunt of the Rose* is in this unsatisfactory state, another translation of his from the French, the *Book of the Lyon* (alluded to in the "Retraction" found, in some manuscripts, at the end of the *Canterbury Tales*), which must certainly have been taken from Guillaume Michault's *Le Dit du lion*, has perished altogether. The strength of French influence on Chaucer's early work may, however, be amply illustrated from the first of his poems with which we are on sure ground, the *Book of the Duchesse*, or, as it is alternatively called, the *Deth of Blaunche*. Here not only are individual passages closely imitated from Machault and Froissart, but the dream, the May morning, and the whole machinery of the poem are taken over from contemporary French conventions. But even at this stage, Chaucer could prove his right to borrow by the skill with which he makes his materials serve his own purpose, and some of the lines in the *Deth of Blaunche* are among the most tender and charming he ever wrote.

Chaucer's *A.B.C.*, a poem in honour of the Blessed Virgin, of which the stanzas begin with the successive letters of the alphabet, is another example of French influence. It is taken from the *Pèlerinage de la vie humaine*, written by Guillaume de Deguileville about 1330. The occurrence of some magnificent lines in Chaucer's version, combined with evidence that he did not yet possess the skill to translate at all literally as soon as rhymes had to be considered, accounts for this poem having been dated some 4 times earlier than the *Book of the Duchesse*, and sometimes sev-

eral years later. With it is usually moved up and down, though it should surely be placed in the '70s, the *Compleynt to Pity*, a fine poem which yet, from its slight obscurity and absence of Chaucer's usual ease, may very well some day prove to be a translation from the French.

Middle Period.—While Chaucer thus sought to reproduce both the matter and the style of French poetry in England, he found other materials in popular Latin books. Among his lost works are renderings of "Origenes upon the Maudeleyne," and of Pope Innocent III. on "The Wrecced Engendring of Mankind" (*De miseria conditionis humane*). He must have begun his attempts at straightforward narrative with the *Lyf of Seynt Cecyle* (the weakest of all his works, the second Nun's Tale in the Canterbury series) from the *Legenda Aurea* of Jacobus de Voragine, and the story of the patience of Grisilde, taken from Petrarch's Latin version of a tale by Boccaccio. In both of these he condenses a little, but ventures on very few changes, though he lets his readers see his impatience with his originals. In his story of Constance (afterwards ascribed to the Man of Lawe), taken from the Anglo-Norman chronicle of Nicholas Trivet, written about 1334, we find him strengthening another weak tale, but still without the courage to remedy its radical faults, though here, as with Grisilde, he does as much for his heroine as the conventional exaltation of one virtue at a time permitted. It is possible that other tales which now stand in the Canterbury series were written originally at this period. What is certain is that at some time in the '70s, independently of any glimpses he may have obtained of the *Divina Commedia* and of Petrarch's sonnets, two notable Italian poems by Boccaccio passed into Chaucer's possession and that the turning of the *Filostrato* into *Troilus and Criseyde* and the *Teseide* into "al the storye of Palamon and Arcyte" was his main poetic business during the next few years and vitally affected his development. He did not, however, work on these masterpieces uninterruptedly. Almost at the outset two court poems had to be written in connection with the betrothal and marriage of Richard II. to Anne of Bohemia, the *Hous of Fame* and *The Parlement of Foules*. The former begins with a dream on a certain tenth of December and Dr. Aage Brusendorf is almost certainly right in linking this with the formal appointment on Dec. 12, 1380, of an English embassy to treat for the marriage and the conception of the poem with Froissart's *Le Temple d'Honneur* in which a marriage is guardedly forecast. Unhappily, one or more leaves at the end of the archetype manuscript of Chaucer's poem were lost before other copies were made from it, so that the conjecture cannot be finally verified, but it offers a much needed clue to the meaning, which had previously been rashly connected with Dante's *Divina Commedia*. Written in octosyllabic couplets, like the *Romaunt of the Rose*, it shows Chaucer already possessed of the conversational ease which marks his later work, but the ease tempted him to extend the poem to a length out of keeping with his subject, and it is best known by the few lines in which he talks about himself. *The Parlement of Foules*, written in seven-line stanzas, commemorating the delay of over a year in the celebration of the marriage, and full of gaiety and humour, is in much better proportion.

Besides these two poems Chaucer about this time produced his most important prose work, the translation of the *De Consolatione Philosophiae* of Boethius. Reminiscences of this helped to enrich many of his subsequent poems and inspired five of his shorter pieces (*The Former Age*, *Fortune*, *Truth*, *Gentillesse* and *Lak of Stidfastnesse*), but the translation itself cannot be counted a success. To borrow Chaucer's own phrase, his "English was insufficient" to reproduce such difficult Latin. The translation is often barely intelligible without the original, and it is only here and there that it flows with any ease or rhythm.

Troilus and Criseyde.—A snatch of abuse of his scrivener shows that the translation of Boethius and *Troilus and Criseyde* were being copied for circulation at the same time and in the *Troilus*, after a good many half-successes, Chaucer achieved a great artistic triumph. He follows Boccaccio's *Filostrato* step by step, but he does not follow it as a mere translator. He had done his duty manfully for St. Cecyle, Grisilde and Constance,

whom he was forbidden by the conventions of his originals to clothe with complete flesh and blood. In this great story of love and betrayal there were no such restrictions, and the characters, which Boccaccio's treatment left thin and conventional, became in Chaucer's hands convincingly human. No other English poem is so instinct with the glory and tragedy of youth, and in the details of the story Chaucer's gifts of vivid colouring, of humour and pity, are all at their highest. *Troilus and Criseyde* is written in seven-line stanzas; for re-telling from the *Teseide* the story of *Palamon and Arcyte* Chaucer used for the first time decasyllabic couplets, for which Guillaume Machault had provided him with a French model, with a great gain in swiftness and compression. The story has not the poignant interest of the *Troilus* (it is probably the "comedy" which in the epilogue to the earlier poems Chaucer promised to write), but Chaucer's skill is again at its highest. This time, while he takes Boccaccio's plot, he takes only as much of it as he wants, and what he takes he heightens and humanizes with the same skill as he had shown in transforming the *Filostrato*. Of the individual characters Theseus himself, the arbiter of the story, is developed as notably as Sir Pandarus in the *Troilus*, while the fair Emilye and her two lovers-at-first-sight receive just as much individuality as they can be given without burdening the story with a greater intensity than it will bear. With what revision we know not, the story was fitted into the *Canterbury Tales* and assigned to the chivalrous Knight; but that it was written soon after *Troilus* and the translation of Boethius, and before the *Legende of Good Women* (in which it is mentioned), should not be doubted, though other theories have been proposed.

When the *Teseide* had been used, Chaucer had no more Italian stories to translate and he turned to his Latin materials to compile a lectionary of Cupid's Saints for presentation to the queen. To atone for his portrayal of the disloyalty of Criseyde he accepted as a penance the painting of 19 women faithful to love, with Alcestis as their queen, enriching his scheme with a delightful prologue (extant in two rather widely differing forms) into which he introduces touches about his worship of the Deity and the controversy between the partisans of the Flower and the Leaf from his French friends, Froissart and Deschamps. Of the stories of constant women, those of Dido and Cleopatra are fully worthy of him. When, however, he had written eight and part of a ninth he wearied of the monotony of his theme, which he was beginning to treat with scant respect, and broke off.

Canterbury Tales.—Chaucer's failure to complete the scheme of the *Legende of Good Women* may have been partly due to the attractions of the *Canterbury Tales*, which were probably taken up in immediate succession to it. His guardianship of two Kentish wards, his justiceship of the peace, his representing the county in the parliament of 1386, his commissionership of the river-bank between Greenwich and Woolwich, all make it easy to understand his dramatic use of the merry crowds he saw on the Canterbury road, without supposing him to have had recourse to Boccaccio's *Decameron*, a book which there is no proof of his having seen. The pilgrims whom he imagines to have assembled at the Tabard inn in Southwark, where Harry Bailey was host, are said to have numbered "wel nyne and twenty in a company," and the Prologue gives full-length sketches (at least some of which Prof. Manly, in his *New Light on Chaucer*, has shown to have been drawn from life) of a Knight, a Squire (his son), and their Yeoman; of a Prioress, Monk, Friar, Oxford Clerk, and Parson, with two disreputable hangers-on of the church, a Summoner, and a Pardoner; of a Serjeant-at-Law and a Doctor of Physic, and of a Franklin, or country gentleman, Merchant, Shipman, Miller, Cook, Manciple, Reeve, Ploughman (the Parson's brother) and the ever-famous Wife of Bath. Five London burgesses are described in a group, and a Nun and Priest (altered possibly in a moment of hopefulness by Chaucer himself, to "priestes three") are mentioned as in attendance on the Prioress. Each of these, with Chaucer himself making the 29th, was pledged to tell two tales, but including one second attempt and a tale told by the Yeoman of a Canon, who overtakes the pilgrims on the road, we have only 20 finished stories, two unfinished and two interrupted ones,

As in the case of the *Legende of Good Women*, our loss is not so much that of the additional stories as of the completed framework. The wonderful character sketches of the Prologue are carried yet farther by the Talks on the Road which link the different tales, and two of these Talks, in which the Wife of Bath and the Pardoner respectively edify the company, have the importance of separate Tales, but between the Tales that have come down to us there are seven links missing, and it was left to a later and weaker hand to narrate, in the "Tale of Beryn," the adventures of the pilgrims at Canterbury.

The reference to the *Lyf of Seynt Cecyle* in the prologue to the *Legende of Good Women* gives external proof that Chaucer included earlier work in the scheme of the *Canterbury Tales*, and mention has been made of other stories which are indisputably early, while in the case of at least two, the Clerk's tale of Grisilde and the Monk's tragedies, there is evidence of early work being revised and supplemented. It is fortunately impossible to separate the prologue to the charmingly told story of "yonge Hugh of Lincoln" from the tale itself, and with the "quod sche" in the second line as proof that Chaucer was here writing specially for his Prioresse we are forbidden to limit the new stories to any one metre or tone. There can be no doubt, however, that what may be called the Tales of the Churls (Miller, Reeve, Summoner, Friar, etc.), and the conversational outpourings of the Pardoner and Wife of Bath, form, with the immortal Prologue, the most important and distinctive additions to the older work. In these, and in the Pardoner's story of Death and the Three Revellers, and the Nun's Priest's masterly handling of the fable of the Cock and Fox, both of them free from the grossness which marks the others, Chaucer takes stories which could have been told in a short page of prose and elaborates them with all the skill in narration which he had sedulously cultivated. The conjugal reminiscences of the Wife of Bath and the Reeve's Tale with its abominable climax (lightened a little by Aleyn's farewell, lines 316-319) are among the great things in Chaucer, as surely as *Troilus* and *Palamon and Arcyte* and the *Prologue*. They help notably to give him the width of range which may certainly be claimed for him.

In or soon after 1391 Chaucer wrote in prose for an 11-year-old reader, whom he addresses as "Litel Lowis my son," a treatise on the use of the Astrolabe, its short prologue being the prettiest specimen of his prose. The wearisome tale of "Melibee and his wyf Prudence," which was perhaps as much admired in English as it had been in Latin and French, may have been translated at any time. The sermon on Penitence, used as the Parson's Tale, was probably the work of his old age. "Envoys" to his friends Scogan and Bukton, a translation of some balades by Sir Otes de Gran-son, and the *Compleynt to his Purs* complete the record of his minor poetry. We have his own statement that in his youth he had written many Balades, Roundels and Virelayes in honour of Love, and the two songs embedded respectively in the *Parlement of Foules* and the Prologue to the *Legende of Good Women* are charming and musical. His extant shorter poems, however, whether early or late, offer no excuse for claiming high rank for him as a lyricist. He had very little sheer singing power, and though there are fine lines in his short poems, witness the famous "Flee fro the prees and dwell with soothfastnesse," they lack the sustained concentration of great work. From the drama, again, Chaucer was cut off, and it is idle to argue from the innumerable dramatic touches in his poems and his gift of characterization as to what he might have done had he lived two centuries later. His own age delighted in stories, and he gave it the stories it demanded invested with a humanity, a grace and strength which place him among the world's greatest narrative poets, and which bring the England of his own day, with all the colour and warmth of life, wonderfully near to his readers.

The part played by Chaucer in the development of the English language has often been overrated. He neither corrupted it, as used to be said, by introducing French words which it would otherwise have avoided, nor bore any such part in fixing it as was afterwards played by the translators of the Bible. The practical identity of Chaucer's language with that of Gower shows that both

merely used the best English of their day with the care and slightly conservative tendency which befitted poets. Chaucer's service to the English language lies in his decisive success having made it impossible for any later English poet to attain fame, as Gower had done, by writing alternatively in Latin and French.

Chaucer borrowed both his stanza forms and his "decasyllabic" couplets (mostly with an extra syllable at the end of the line) from Guillaume Machault, and his music, like that of his French master and his successors, depends very largely on assigning to every syllable its full value, and more especially on the due pronunciation of the final *-e*. The slower movement of change in Scotland allowed time for Chaucer to exercise a potent influence on Scottish poetry, but in England this final *-e*, to which most of the earlier grammatical forms by Chaucer's time had been reduced, itself fell rapidly into disuse during the 15th century, his disciples, Hoccleve and Lidgate, quickly lost touch with his rhythms and successive copyists reduced his text to a state in which it was only by accident that lines could be scanned correctly. For fully three centuries his reputation was sustained solely by his narrative power, his warmest panegyrists betraying no consciousness that they were praising one of the greatest technical masters of poetry. Even when thus maimed, however, his works found readers and lovers in every generation, and every improvement in his text has set his fame on a surer basis.

BIBLIOGRAPHY.—The *Canterbury Tales* have always been Chaucer's most popular work, and, including fragments, upwards of 60 15th century manuscripts of it still survive. Two thin volumes of his minor poems were among the little quartos which Caxton printed by way of advertisement immediately on his return to England; the *Canterbury Tales* and *Boethius* followed in 1478, *Troilus* and a second edition of the *Tales* in 1483, the *Hous of Fame* in 1484. The *Canterbury Tales* were subsequently printed in 1492 (Pynson), 1498 (de Worde) and 1526 (Pynson); *Troilus* in 1517 (de Worde) and 1526 (Pynson); the *Hous of Fame* in 1526 (Pynson); the *Parlement of Foules* in 1526 (Pynson) and 1530 (de Worde), and the *Mars, Venus and Envoy to Bukton* by Julian Notary about 1500. Pynson's three issues in 1526 almost amounted to a collected edition, but the first to which the title *The Workes of Geoffrey Chaucer* was given was that edited by William Thynne in 1532 for Thomas Godfray. Of this there was a new edition in 1542 for John Reynes and William Bonham, and an undated reprint a few years later for Bonham, Kele, Petit and Toye, each of whom put his name on part of the edition. In 1561 a reprint, with numerous additions, edited by John Stowe, was printed by J. Kyngston for J. Wight, and this was re-edited, with fresh additions by Thomas Speght, in 1598 for G. Bishop and again in 1602 for Adam Islip. In 1687 there was an anonymous reprint, and in 1721 John Urry produced the last and worst of the folios. By this time the paraphraseres were already at work, Dryden rewriting the tales of the Knight, the Nun's Priest and the Wife of Bath, and Pope the Merchant's. In 1737 (reprinted in 1740) the Prologue and Knight's Tale were edited (anonymously) by Thomas Morell "from the most authentic manuscripts," and here, though by dint of much violence and with many mistakes, Chaucer's lines were for the first time in print given in a form in which they could be scanned. This promise of better things was fulfilled by a fine edition of the *Canterbury Tales* (1775-78), in which Thomas Tyrwhitt's scholarly instincts produced a comparatively good text from second-rate manuscripts and accompanied it with valuable illustrative notes. The next edition of any importance was that edited by Thomas Wright for the Percy Society in 1848-51, based on the erratic but valuable British Museum manuscript Harley 7.334. In 1866 Richard Morris re-edited this text in a more scholarly manner for the Aldine edition of the British Poets.

In 1868 the foundation of the Chaucer Society, with Dr. Furnivall as its director and chief worker, and Henry Bradshaw as a leading spirit, led to the publication of a six-text edition of the *Canterbury Tales*, and the consequent discovery that a manuscript belonging to the earl of Ellesmere, though undoubtedly "edited," contained the best available text. The Chaucer Society also printed the best manuscripts of *Troilus* and *Criseyde* and of all the minor poems, and thus cleared the way for the "Oxford" Chaucer, edited by Prof. Skeat, with a wealth of annotation, for the Clarendon Press in 1894, the text of which was used for the splendid folio printed two years later by William Morris at the Kelmscott Press, with illustrations by Sir Edward Burne-Jones. A supplementary volume of the Oxford edition, entitled *Chaucerian and other Pieces*, issued by Prof. Skeat in 1897, contains the prose and verse which his early publishers and editors, from Pynson and Thynne onwards, included among his Works by way of illustration, but which had gradually come to be regarded as forming part of his text. Many of these pieces have now been traced to other authors, and their exclusion has helped to clear not only Chaucer's text but also his biography, which used (as in the "Life" published by William Godwin in two

quarto volumes in 1803) to be encumbered with inferences from works now known not to be Chaucer's, notably the *Testament of Love* written by Thomas Usk. See Eleanor P. Hammond, *Chaucer; a Bibliographical Manual* (1909); J. S. P. Tatlock and A. G. Kennedy, *A Concordance to the Complete Works of Geoffrey Chaucer and to the Romaunt of the Rose* (Carnegie Institute, Washington, 1927).

(A. W. P.)

CHAUDESAIGUES, a village of central France, in the department of Cantal, at the foot of the mountains of Aubrac, 19 m. S.S.W. of St. Flour. Pop. (1926) 870. It has hot mineral springs, which at their maximum rank as the hottest in France. The water, which contains bicarbonate of soda, is employed medicinally, and also for washing fleeces, incubating eggs and various other economic purposes; and it furnishes a ready means of heating the houses of the town during winter. In the immediate neighbourhood is the cold chalybeate spring of Condamine. The warm springs were known to the Romans, and are mentioned by Sidonius Apollinaris.

CHAUFFEUR. In its anglicized sense, the common name for a professional driver of a motor-vehicle. The word is French (from *chauffer*, to heat) and, primarily used for a man in charge of a forge or furnace, came to describe a stoker on a locomotive or steamship.

CHAULIAC, GUY DE (GUIDO DE CAULIACO) (c. 1300–1368), French surgeon, was born at Chauliac (Auvergne). He studied at Toulouse, Montpellier and Paris, and then went to Bologna to study anatomy under Nicolo Bertuccio. Chauliac was one of the most learned men of his time, and his book, *Chirurgia magna* (1363), passed through many translations and was for a long time the standard work on the subject. It was first printed in French at Lyons in 1478 (modern ed. by E. Nicaise, Paris 1890). Guy died on July 25, 1368, at Avignon, where he was physician to the pope. He operated for hernia and cataract, which had hitherto been treated mainly by charlatans, and has left a description of the narcotic inhalation given to patients.

See the introduction by E. Nicaise to his edition of Guy's *La Grande Chirurgie* (1890), with bibliography.

CHAULIEU, GUILLAUME AMFRYE DE (1639–1720), French poet and wit, was born at Fontenay, Normandy. His father, *maître des comptes* of Rouen, sent him to study at the Collège de Navarre. Louis Joseph, duke of Vendôme, and his brother Philippe, grand prior of the Knights of Malta in France, at that time had a joint establishment at the Temple, where they gathered round them a very gay and reckless circle. Chaulieu received the abbey of Aumate and other benefices from the duke; and became the constant companion and adviser of the two princes. He made an expedition to Poland in the suite of the marquis de Béthune, but returned to Paris without securing any advancement. In his later years Chaulieu spent much time at the little court of the duchesse du Maine at Sceaux. There he became the trusted and devoted friend of Mlle. Delaunay. Among his poems the best known are "Fontenay" and "La Re-traite."

Chaulieu's works were edited, with those of his friend the marquis de la Fare, in 1714, 1750 and 1774. See also C. A. Sainte-Beuve, *Causeries du lundi*, vol. i.; and *Lettres inédites* (1850), with a notice by Raymond, marquis de Berenger.

CHAUMETTE, PIERRE GASPARD (1763–1794), French revolutionary, was born at Nevers on May 24, 1763. Until the Revolution he lived a somewhat wandering life, interesting himself particularly in botany. He was a student of medicine at Paris in 1790, became one of the orators of the club of the Cordeliers, and contributed anonymously to the *Révolutions de Paris*. As member of the insurrectionary Commune of Aug. 10, 1792, he was delegated to visit the prisons, with full power to arrest suspects. He was elected president of the Commune, defending the municipality in that capacity at the bar of the Convention on Oct. 31, 1792. Chaumette was one of the ring-leaders in the attacks of May 31 and of June 2, 1793, on the Girondists, towards whom he showed himself relentless. He was one of the promoters of the worship of Reason, and on Nov. 10, 1793, he presented the goddess to the Convention in the guise of an actress. On the 23rd he obtained a decree closing all the

churches of Paris, and placing the priests under strict surveillance; but on the 25th he retraced his steps and obtained from the Commune the free exercise of worship. Robespierre had him accused with the Hébertists; he was arrested, imprisoned in the Luxembourg, condemned by the Revolutionary tribunal and executed on April 13, 1794. Chaumette was an ardent social reformer; he secured the abolition of corporal punishment in the schools, the suppression of lotteries, of houses of ill-fame and of obscene literature; he instituted reforms in the hospitals, and insisted on the honours of public burial for the poor.

See *Mémoires de Chaumette sur la Révolution du 10 août 1792*, ed., with biographical intro. by F. A. Aulard (1893).

CHAUMONT, a town of eastern France, capital of the department of Haute-Marne, a railway junction 163 m. E.S.E. of Paris on the main line of the Eastern railway to Belfort. Pop. (1926) 12,892. Chaumont is situated on high ground at the confluence of the Marne and Suize. It received a charter from the counts of Champagne in 1190. The church of St. Jean-Baptiste dates from the 13th century, the choir and lateral chapels belonging to the 15th and 16th. The sculptured triforium (15th century), the spiral staircase in the transept and a Holy Sepulchre are of interest. The Tour Hautefeuille (a keep of the 11th century) is the principal relic of a château of the counts of Champagne; the rest of the site is occupied by the law courts. In 1814 Great Britain, Austria, Russia and Prussia concluded at Chaumont the treaty by which they bound themselves not to conclude a separate peace and to prosecute the Napoleonic war to a successful issue. Chaumont is the seat of a prefect and of a court of assizes, and has tribunals of first instance and of commerce. The main industries are glove-making and leather-dressing. The town has trade in grain, iron (mined in the vicinity) and leather.

CHAUNCEY, ISAAC (1772–1840), American naval commander, was born at Black Rock, Conn., Feb. 20, 1772. He was brought up in the merchant service, and entered the U.S. Navy as a lieutenant in 1798. The most active period of his life was that of his command on the Great Lakes during the War of 1812. He took the command at Sackett's harbor on Lake Ontario in October 1812. Commodore Chauncey brought from 400 to 500 officers and men with him, and local resources for building being abundant, he had by November formed a squadron of ten vessels, with which he attacked the Canadian port, York, taking it in April 1813. The Americans had the advantage of commanding greater resources for shipbuilding. Sir James Yeo began by blockading Sackett's harbor in the early part of 1814, but when the American squadron was ready he was compelled to retire by the disparity of the forces. Commodore Chauncey was now able to blockade the British flotilla at Kingston. During his later years he served as commissioner of the Navy, and was president of the board of naval commissioners from 1833 till his death at Washington, Feb. 27, 1840.

See Roosevelt's *War of 1812* (1882); and A. T. Mahan, *Sea Power in its Relations to the War of 1812* (1905); also see E. Channing, *History of the United States*, vol. iv. (1926).

CHAUNCEY, CHARLES (1592–1672), president of Harvard college, was born at Yardley-Bury, England, in Nov. 1592, and attended Trinity college, Cambridge. He was in turn vicar at Ware and at Marston St. Lawrence, but twice incurred censure from the authorities for nonconformity. His formal recantation in Feb. 1637 caused him lasting self-reproach. In this same year he emigrated to America, where he was an associate pastor at Plymouth, then pastor at Scituate (Mass.), and, from 1654 until his death, president of Harvard college. He died on Feb. 19, 1672. According to Mather, he was "a most incomparable scholar." His writings include: *The Plain Doctrine of the Justification of a Sinner in the Sight of God* (1659) and *Antisynodalia Scripta Americana* (1662).

His great-grandson, CHARLES CHAUNCEY (1705–1787), a prominent American theologian, was born in Boston (Mass.), on Jan. 1, 1705, and graduated at Harvard in 1721. In 1727 he was chosen as the colleague of Thomas Foxcroft in the First Church of Boston, continuing as pastor until his death. He condemned

the "Great Awakening" as an outbreak of emotional extravagance in his sermon *Enthusiasm*, and in his *Seasonable Thoughts on the State of Religion in New England* (1743), written in answer to Jonathan Edwards' *Some Thoughts Concerning the Present Revival of Religion in New England* (1742). Before and during the War of Independence he ardently supported the patriot party. He died in Boston on Feb. 10, 1787. His publications include: *Salvation of All Men, Illustrated and Vindicated as a Scripture Doctrine* (1782) and *Five Dissertations on the Fall and its Consequences* (1785).

For Charles Chauncy see Cotton Mather's *Magnalia Christi Americana* (1702) and W. C. Fowler's *Memorials of the Chauncys* (1858). For the younger Chauncy see P. L. Ford's privately printed *Bibliotheca Chaunciana* (1884), and Williston Walker's *Ten New England Leaders* (1901).

CHAUNY, a town of northern France in the department of Aisne, 19 m. S. by W. of St. Quentin by rail. Pop. (1926) 9,000. The town is situated on the Oise (which here becomes navigable) and at the junction of the canal of St. Quentin with the lateral canal of the Oise. It contains mirror-polishing works, chemical works and metal foundries. It was the scene of much fighting in the Hundred Years' War.

CHAUSSES. Mediaeval protective leg-harness or mail hose. Modern French *chausse*: stocking, hose. The term also refers to light pantaloons covering the hips, legs and feet.

CHAUTAUQUA, an unincorporated village of Chautauqua county, New York, U.S.A., in a township of the same name, on the west shore of Chautauqua lake, a beautiful body of water 1,300 ft. above sea-level, 17 m. long and 3 m. across at its greatest width. It is served by motor-coach and electric lines, connecting with railways at Westfield and Jamestown, at either end of the lake. The resident population of the town in 1930 Federal census was 3,802. The village contains the campus and equipment of the Chautauqua institution. (See LYCEUMS AND CHAUTAUQUAS.)

CHAUVIGNY, a town of western France in the department of Vienne, 20 m. E. of Poitiers by rail. Pop. (1926) 2,515. The town is finely situated overlooking the Vienne, and has two interesting Romanesque churches, both restored in modern times. It was a strong fortress in the middle ages, and still possesses the ruins of no less than five castles, the chief of which is the *Château Baronnial* (11th and 15th centuries) the old seat of the bishops of Poitiers, who were lords of Chauvigny.

CHAUVINISM, a term for unreasonable and exaggerated patriotism, the French equivalent of "Jingoism." The word originally signified idolatry of Napoleon, being taken from a much-wounded veteran, Nicholas Chauvin, who, by his adoration of the emperor, became the type of blind enthusiasm for military glory.

CHAUX DE FONDS, LA, an industrial town in the Swiss canton of Neuchâtel, about 19 m. by rail N.W. of Neuchâtel, at a height of about 3,250 ft. in a valley of the same name in the Jura. Pop. (1920) 37,708; mainly Protestant (29,420) and French-speaking; of the 6,436 "Catholics" the majority are "Old Catholics." It is a centre of the watch-making industry. There are schools of watch-making and of industrial art.

See *Dict. hist. et biogr. de la Suisse*, ii.

CHAVANTEAN, a small independent linguistic stock of South American Indians, so called from the Chavantes or Caingangs, its most important tribe. The Chavantean tribes are found to-day on the upper Parana and Lower Paranapanema rivers, in the state of São Paulo, Brazil. They formerly occupied a somewhat larger territory. These Chavantes are to be carefully distinguished from the tribe of the same name in the States of Goyaz and Matto Grosso, who belong to the Ges (*q.v.*) stock. The Chavantes are quite dark-skinned, rather timid hunting folk, of very primitive culture. They are very little known. Both sexes wear small bast breech-clouts, but no other clothing. Their dwellings are tiny thatched huts, and their weapons the bow and spear. They have no pottery or textiles.

See H. von Ihering, *The Anthropology of the State of S. Paulo, Brazil* (2nd ed. S. Paulo, 1906).

CHAVASSE, FRANCIS JAMES (1846–1928), the son of Thomas Chavasse, of Sutton Coldfield, and brother of Sir

Thomas Chavasse, the Birmingham surgeon, was born on Sept. 27, 1846. He was educated privately, and later at Corpus Christi college, Oxford. He was ordained in 1870, and in 1878 became vicar of St. Peter-le-Bailey, Oxford, and a year later principal of Wycliffe hall. In 1900, on the resignation of Dr. J. C. Ryle, the first bishop of Liverpool, Chavasse was appointed to the vacant see. He was remarkable for his ability in finding common interests for people of very different types and holding very different views, and in bringing them together to work for a common purpose. This gift proved invaluable in the execution of the great scheme for the building of Liverpool cathedral (on the plans designed by Sir Giles Gilbert Scott, R.A.) with which his name will always be associated. He resigned his bishopric in 1923, owing to his advanced years, and died on March 11, 1928.

CHAVES, a town of northern Portugal, in the district of Villa Real, 8 m. S. of the Spanish frontier. Pop. (1911), 6,820. Chaves is the ancient *Aquae Flaviae*, famous for its hot saline springs, which are still in use. A fine Roman bridge of 18 arches spans the Tamega. Chaves was long one of the principal frontier fortresses, and may derive its present name from the position which makes it the "keys" (*chaves*) of the north. One of its churches contains the tomb of Alphonso I. of Portugal (1139–85).

CHEADLE, a small town in the urban district of Cheadle and Gatley (pop. 1931, 18,469), in Cheshire, England, 6 m. S. of Manchester. The name occurs in the formerly separate villages of Cheadle Hulme, Cheadle Bulkeley and Cheadle Moseley. Cheadle is one of the numerous townships of modern growth which fringe the southern boundaries of Manchester, and practically form suburbs of that city. Stockport lies immediately to the east. There are cotton printing and bleaching works in the locality.

CHEADLE, market town of north Staffordshire, England, 13 m. N.N.E. of Stafford, on the L.M.S.R. Pop. (1921) 6,178. The Roman Catholic church of St. Giles, with a lofty spire, was designed by Pugin and erected in 1846. There are collieries in the neighbourhood, and silk and other textile works in the town. Metal-working is also carried on. Pop. rural dist. (1931) 27,445.

CHEATING, "the fraudulently obtaining the property of another by any deceitful practice not amounting to felony, which practice is of such a nature that it directly affects, or may directly affect, the public at large" (Stephen, *Digest of Criminal Law*). Cheating is either a common law or statutory offence, and is punishable as a misdemeanour. An indictment for cheating at common law is of comparatively rare occurrence, and the statutory crime usually presents itself in the form of obtaining money by false pretences (*q.v.*).

CHEBICHEV, PAFNUTIY LVOVICH (1821–1894), after N. I. Lobachevskiy, the most distinguished of Russian mathematicians, was born at Borovsk on May 26, 1821. Educated at the University of Moscow in 1859, he became professor of mathematics in the University of St. Petersburg, a position from which he retired in 1880. He became a correspondent in 1860, and in 1874 *associé étranger* of the Institute of France. He was also a foreign member of the Royal Society of London. In 1841 he published a valuable paper, "Sur la convergence de la série de Taylor," in *Crelle's Journal*. He wrote much on prime numbers; in one paper ("Sur les nombres premiers," 1850) he established the existence of limits within which must be comprised the sum of the logarithms of the primes inferior to a given number. He devoted much attention to the problem of obtaining rectilinear motion by linkage. The "Chebichev's parallel motion" is a three-bar linkage, which gives a very close approximation to exact rectilinear motion, but he failed to devise one producing true rectilinear motion. Such a linkage was discovered by one of his pupils, Lipkin, who, however, had been anticipated by A. Peaucellier. His mathematical writings cover a wide range of subjects, such as the theory of probabilities, quadratic forms, theory of integrals, gearings, the construction of geographical maps, etc. He also published a *Traité de la théorie des nombres*. He died at St. Petersburg on Dec. 8, 1894.

CHEBOYGAN, a city of Michigan, U.S.A., on south channel of the Strait of Mackinac, at the mouth of the Cheboygan river; a port of entry and the county seat of Cheboygan county. It is on

Federal highways 23 and 27, and is served by the Michigan Central and the Detroit and Mackinac railways, and by lake steamers during the navigation season. The population in 1930 was 4,923. Cheboygan is in the heart of the summer resort region of northern Michigan, and is surrounded by a farming, stock-raising and fruit-growing country. The city has sundry manufacturing industries, and is an important fishing port, shipping 3,000,000 lb. of fish to eastern markets in 1927. There are large silver fox farms near by. The commerce of the port declined from the peak of 700,998 tons in 1898 to 36,340 tons in 1925. Cheboygan (at first called Duncan and later Inverness) was settled in 1846, and chartered as a city in 1889.

CHECHEN AUTONOMOUS AREA. A district in the North Caucasian area of the Russian Socialist Federal Soviet Republic, created an autonomous area in Nov. 1920. Area, 10,015 sq.km. Pop. (1926), 311,005, entirely rural. It consists mainly of the densely wooded slopes of the northern Caucasus, and extends from the Caucasus to the Terek river, and from Ingushetia to Dagestan. The naphtha region of Grozny, which lies in the area, forms a separate province and its area and population are not included in the figures given above, though the Chechen area is administered from the town of Grozny. In the north the forest thins out and its place is taken by steppe with chestnut brown soil, less fertile than the black earth, but suitable for agriculture in years of good rainfall. The latter varies in quantity in the north, but is more abundant on the southern hill slopes. The density of population is about 30 per sq.km.; the Chechens are the most numerous of the native hill tribes in the North-Caucasian area, forming 2.7% of the total population. The Chechen, Tchetchen (or Khists [Kisti], as they are called by the Georgians) call themselves "Nakhtche" (people). They fought fiercely against Russian aggression under Daūd Beg, Oman Khan and Shamyl, in the 18th century, and under Khazi-Mollah in the 19th century. Many of them migrated to Armenia in 1859, after the surrender of their chieftain Shamyl. They are Mohammedans, and they are governed by popular assembly in each commune, every man considering himself free and equal to his neighbour. Towards the north settled agriculture has been introduced by Russian immigrants and winter wheat, millet, oats and barley are grown. Working cattle are used in preference to horses. But, in the southern hill oak, beech, birch and pine forest and alpine pasture area, the Chechens are hunters or nomad herdsmen, taking their goats and sheep to the high meadows in the spring, and descending in autumn to the lower, more sheltered areas. They sow oats and barley under great difficulties, often having to remove the stones brought down by the spring floods from their tiny cultivated patches, and even in summer snow may fall. Their goats supply them with milk, and their sheep with meat, leather and wool; koustar (peasant) industries include spinning, weaving, preparing leather and the making of knives and daggers. Bees are kept and a saw-milling industry is being introduced; three new saw-mills were built in 1926-27. Cultural life is at a low level: there is a high percentage of illiteracy, and this, combined with the absence of roads and the impossibility of using the mountain streams (the Sunzha and Argun and their tributaries) for passenger navigation, makes cultural and economic progress difficult. Many mountain Chechens live in windowless hovels of mud and stone in the winter, and, in the summer, on the Alpine pastures, improvise shelters from boughs. The two main roads are from Grozny to Shatoi on the Argun river, and a road farther east almost parallel to it, passing south into Dagestan. There is telegraphic communication along these roads. From Gydermes junction a loop of the Caspian-Black sea railway passes through Grozny to Beslan, from which a branch goes to Vladikavkaz.

CHECKERS, the name by which the game of draughts (*q.v.*) is known in America. The origin of the name is the same as that of "chess" (*q.v.*).

CHEDDAR, town, Somersetshire, England, 22m. S.W. of Bristol by G.W.R. Pop. (1921) 2,007. To the west lies the low Axe valley, to the east rise immediately southwest the Mendip cliffs (600-800ft.) of Cheddar gorge, with beautiful stalactitic

caverns, of which Cox's and Gough's are best known. The remains discovered in the caves and elsewhere in the neighbourhood give evidence of prehistoric and Roman settlements at Cheddar (*Cedre*, *Chedare*), which was a convenient trade centre. The manor of Cheddar was a royal demesne in Saxon times, and the witenagemot was held there in 966 and 968. It was granted by John in 1204 to Hugh, archdeacon of Wells. The bishop of Bath and Wells granted it to the king in 1553. It is now owned by the marquis of Bath. By a charter of 1231 extensive liberties in the manor of Cheddar were granted to Bishop Joceline, who in 1235 obtained the right to hold a weekly market and fair. By a charter of Edward III. (1337) Cheddar was removed from the king's forest of Mendip. The market was discontinued about 1690. Fairs are now held on May 4 and Oct. 29 under the original grants. The name of Cheddar is given to a well-known species of cheese (*see* DAIRY), the manufacture of which began in the 17th century in the town and neighbourhood.

CHEDUBA or **MAN-AUNG**, an island in the Bay of Bengal, situated 10 m. from the coast of Arakan, between 18° 40' and 18° 56' N., and between 93° 31' and 93° 50' E. It forms part of the Kyaukpyu district of Arakan. It extends about 20 m. in length from north to south, and 17 m. from east to west, and its area of 220 sq.m. supports a population of nearly 30,000. The channel between the island and the mainland is navigable for boats, but not for large vessels. The surface of the interior is richly diversified by hill and dale, and in the southern portion some of the heights exceed a thousand feet in elevation. There are various indications of former volcanic activity, and along the coast are earthy cones covered with green-sward, from which issue springs of muddy water emitting bubbles of gas. Copper, iron and silver ore have been discovered; but the island is chiefly noted for its petroleum wells. The inhabitants of the island are mainly Maghs. Cheduba fell to the Burmese in the latter part of the 18th century, and was taken by the British in 1824.

CHEERING, the uttering or making of sounds encouraging, stimulating or exciting to action, indicating approval or acclaiming or welcoming persons, announcements of events and the like. The word "cheer" meant originally face, countenance, expression (Low Lat. *cara*), and was at first qualified with epithets, both of joy and sorrow; compare "She thanked Dyomedes for alle . . . his gode chere" (Chaucer, *Troilus*) with "If they sing . . . 'tis with so dull a cheere" (Shakespeare, *Sonnets*, xcvi.). An early transference in meaning was to hospitality or entertainment, and hence to food and drink, "good cheer." The sense of a shout of encouragement or applause is a late use.

Of the different words or sounds that are used in cheering, "hurrah," though now generally looked on as the typical British form of cheer, is found in various forms in German, Scandinavian, Russian (*urá*), French (*houa*); it is probably onomatopoeic in origin. The German *hoch*, the French *vive*, Italian and Spanish *viva*, *evviva*, are cries rather of acclamation than encouragement. The Japanese shout, *banzai*, became familiar during the Russo-Japanese War. In reports of parliamentary debates "cheers" indicates that approval was shown by emphatic utterances of "hear hear." Cheering may be tumultuous or it may be conducted rhythmically by prearrangement, as in the case of the "Hip-hip-hip" by way of introduction to a simultaneous "hurrah."

Rhythmical cheering has been developed to its greatest extent in America in the college yells, which may be regarded as a development of the primitive war-cry. The original yells of Harvard and Yale are identical in form, being composed of *rah* (abbreviation of *hurrah*) nine times repeated, shouted in unison with the name of the university at the end. The Yale cheer is given faster than that of Harvard. Many institutions have several different yells; the best known of these variants is the Yale cheer, partly taken from the *Frogs* of Aristophanes:

Brekekekéx, ko-áx, ko-áx,
Brekekekéx, ko-áx, ko-áx,
O-óp, O-óp, parabaloú,
Yale, Yale, Yale,
Rah, rah, rah, rah, rah, rah,
rah, rah, rah,
Yale! Yale! Yale!

The "triple cheer" of Princeton is:

H'ray, h'ray, h'ray,
Tiger, tiger, tiger,
Siss, siss, siss,
Boom, boom, boom,
Ah, ah, ah,
Princeton, Princeton, Princeton!

The "railroad cheer" is like the foregoing, but begun very slowly and broadly, and gradually accelerated to the end, which is enunciated as fast as possible. Many cheers are formed like that of Toronto university:

Varsity, varsity,
V-a-r-s-i-t-y (spelled)
VAR-SIT-Y (spelled *staccato*)
Vár-si-tý,
Rah, rah, rah!

The cheer of the United States Naval academy is an imitation of a nautical syren. The Amherst cheer is:

Amherst! Amherst! Amherst! Rah! Rah!
Amherst! Rah! Rah!
Rah! Rah! Rah! Rah! Rah! Rah! Amherst!

Besides the cheers of individual institutions there are some common to all, generally used to compliment some successful athlete or popular professor. One of the oldest examples of these personal cheers is:

Who was George Washington?
First in war,
First in peace,
First in the hearts of his countrymen,

followed by a stamping on the floor in the same rhythm.

College yells are used particularly at athletic contests. In any large college there are several leaders, chosen by the students, who stand in front and call for the different songs and cheers, directing with their arms in the fashion of an orchestral conductor. Cheering and singing form one of the distinctive features of inter-collegiate and scholastic athletic contests in America.

CHEESE. The making of cheese is one of the primitive operations of husbandry. Indeed cheese may almost be termed a natural product, as milk on turning sour coagulates and the "curd" thus formed is crude cheese. But, in practice, the curd is separated from the "whey" by the use of rennet which is made from the gastric juice of calves, extracted from the skin of the stomach.

British Cheese.—Cheese has always been a popular article of diet. In mediæval farming cheese-making was one of the regular duties of every farmer's wife. Cheese was usually made of skim milk, although, no doubt, whole-milk cheese was made for the tables of lords of the manor and others who lived more daintily than the farming class. The general quality was inferior and as late as the 17th century writers on agriculture placed English cheese, in order of merit, below that produced in Italy, Holland and France. There were many local varieties of English cheese and some were better than others. Cheddar and Cheshire gained a high reputation for cheese which they have retained and enhanced. Shropshire and Banbury cheese were also in repute two or three centuries ago. Banbury cheese is classed by one writer as the best, although Bardolph's use of the term as a contemptuous epithet (*Merry Wives of Windsor*) does not suggest that it stood high in popular favour. Whatever its merits it has now disappeared, and Shropshire cheese is unknown in modern markets. Essex and Kent also gave their name to varieties of cheese which are now obsolete. It was in the next century that the variety which many would place first of all—the Stilton—was introduced. Lord Ernle gives the following account of its origin—"Mrs. Paulet of Wyndham, in the Melton district of Leicestershire, is said to have been the first maker of Stilton cheeses. She supplied them to Cooper Thornhill, who kept the Bell Inn at Stilton (Hunts) on the great north road from London to Edinburgh, and they became famous among his customers, and throughout England. The manufacture of Stilton cheeses became an industry of the district. Mrs. Paulet was still living in 1780."

The principal kinds of cheese now made in England are Cheddar, Cheshire, Stilton, Gloucester, Wensleydale, Derbyshire, Lei-

cestershire, Cotherstone, Lancashire and Dorset. These are all "hard" cheeses. There are several kinds of "soft" cheeses, the most common being "cream" cheese. (*See DAIRY FARMING.*)

The total quantity of cheese made on the farms of England and Wales is estimated at 25,100 tons, having a value of £2,740,000. About 5% of all the milk produced is used in making cheese.

British Imports.—The imports of cheese into Great Britain, on the average of the three years 1924–26 were 150,000 tons, the quantity in 1926 being 150,665 tons. The chief sources and the quantity received from each in 1926 were:

| | Tons |
|-----------------------|--------|
| New Zealand | 74,873 |
| Canada | 52,754 |
| Netherlands | 9,499 |
| Italy | 7,061 |
| Australia | 2,349 |
| U.S.A. | 660 |

Of imported cheese about 2,000 tons were re-exported and there was also an export of 1,336 tons of British-made cheese.

Next to Great Britain the chief importing countries, some of which also export cheese but on balance buy more than they sell, are the United States, Belgium, Germany, France, Austria, Algiers, Egypt and Spain. The chief exporting countries, in order of the magnitude of trade, are New Zealand, Holland, Canada, Italy, Switzerland, Denmark, the Serb-Croat-Slovene State, Australia and Finland.

In the cheese trade the sort known as "Cheddar" is in much the largest supply. The name has now no local significance but implies a distinctive method of manufacture. Practically all cheese imported from Canada is "Cheddar" and is frequently described as "Canadian Cheddar." Many kinds of cheese are made on the Continent of Europe. In Holland the Gouda and Edam varieties form the bulk of the exports from that country. Italy is famous for Gorgonzola and Parmesan cheeses, which are exported in considerable quantities. Several varieties of cheese are made in Switzerland but that which is mostly exported is Gruyère. France exports many soft cheeses including Camembert, Bondon, Brie, Coulommiers, Pont l'Évêque and Neuchâtel.

The first cheese-factory in the British Isles was opened in 1871 at Derby and the second at Longford in the same county.

(R. H. R.)

Edam cheese is a hard, rennet cheese produced in Holland. The cheeses are round and are coloured deep red on the surface and wrapped in tin foil, or enclosed in an air tight tin. *Gorgonzola* is a rennet, Italian cheese made from whole milk of cows. The cheeses are cylindrical in shape and are packed with straw in wicker baskets. The interior is mottled with a penicillium much like Roquefort and Stilton varieties. Roquefort is a soft rennet cheese made from the milk of sheep, which is sometimes mixed with cow's milk. *Parmesan* is a cheese used largely for soups and with macaroni in grated form. It is of Italian manufacture and is known by many names. There are probably about 18 distinct varieties of cheese. All the rest, consisting of more than 400, are of local origin, usually named after towns or communities. (*See U.S. Dept. Agriculture, Bul. 608, May 1928.*)

United States Cheese.—Cheese was first made in the United States by women in the farm homes of the early settlers. The cheese, which was similar to English Cheddar, later became known as "American" cheese. The modern factory system of cheese-making was developed between 1850 and 1860 and manufacture on the farms practically disappeared in the next 30 years. Many improvements in cheese-making have since been perfected.

Approximately 450,000,000 lb. of cheese of all varieties have been made yearly since 1924, requiring slightly less than 4% of the total milk production. Cheese is made in nearly all the northern and some of the southern States, but Wisconsin and New York lead. Cheese-making is declining in districts where the demand for milk for fluid consumption prevails. Perishable types are still profitably made near the large cities, but the trend of production is toward more remote agricultural regions.

Several kinds of cheese are made. American, the most important single type, is a hard ripened cheese, usually made from whole-milk. It is manufactured in various sizes and shapes, such

as Cheddars, Flats, Long Horns, and Young Americas. American and some other varieties are sometimes melted and moulded into loaves or small prints which are then sold under the name of "Pasteurized-blended" or "Process" cheese. Certain soft unripened cheese, such as Cream, Neuchatel, Cottage, Pot and Bakers', are also made in large quantities. Cream and Neuchatel are rich in milk fat; the others are made from skim-milk but are usually mixed with cream when eaten. The remaining kinds of cheese of commercial importance made in the United States are Swiss, Brick, Münster and Limburger. A few Italian and French varieties are produced in relatively small quantities.

Cheese is usually marketed by the producers through co-operative associations and cheese buyers or dealers. Selling prices are based on current quotations established as a result of trading in certain of the large cheese markets. Attempts are being made by the U.S. Department of Agriculture and the Wisconsin department of markets to classify all cheese sold according to quality. These efforts, although only partly successful, indicate the tendency toward more systematic methods of marketing. Exports are insignificant. Imports, which approximate 60,000,000 lb. yearly, seem to be increasing slowly. The chief sources are Italy, Switzerland and France. Statistics are available in the *Yearbook of the United States Department of Agriculture*. (W. V. P.)

The per capita consumption of cheese in various countries follows:

| | lbs. | | lbs. |
|------------------------|-------|--------------------------|------|
| Switzerland . . . 1923 | 23.30 | Great Britain . . . 1921 | 8.90 |
| Netherlands . . . 1923 | 13.50 | Argentina . . . 1924 | 4.09 |
| France . . . 1923 | 13.50 | Canada . . . 1926 | 3.92 |
| Denmark . . . 1922 | 13.20 | United States . . . 1921 | 3.50 |
| Germany . . . 1912 | 9.50 | United States . . . 1924 | 4.36 |

CHEESE-MAKING

Cheese may be divided into two classes, "hard" and "soft," and "hard" cheese again into three kinds made respectively from whole milk, skim milk or double cream.

Cheese is coagulated milk, the process of coagulation, analogous to that of digestion in the human stomach, being induced by the use of rennet, which is an extract from the mucous membrane of the fourth stomach of the calf. The stomach is cleaned and preserved by salting and drying. When wanted the dried skin or "vell," as it is termed, is macerated in brine for some hours, well rubbed to get the strength out of it, and the liquid put into the milk. The making of rennet was once an essential part of the cheese-makers' business, but rennet extracts are now generally bought, being preferable for their uniformity and convenience.

Camembert Cheese is a soft variety originating in the arrondissement of that name in the neighbourhood of Lisieux, France. It is made from cow's milk, coagulated with rennet; the curd is dipped into a perforated hoop about 4½ in. in diameter and 5 in. in height in which the whey separates out by gravity. The newly made cheeses when firm enough to handle are rolled in or sprinkled with salt and placed upon mats and ripened over a period of three to five weeks by the action of the molds *Penicillium camemberti* and *Oidium (Oospora) lactis*, in specially constructed rooms held at about 50° to 58° F and at a relative humidity of about 88%. As marketed a Camembert cheese is about 1½ in. in thickness, 4 to 4½ in. in diameter, covered by a moldy and more or less slimy rind perhaps ¼ to ½ in. in thickness. The cheeses are usually wrapped, boxed separately, and shipped when from two to three weeks old, and the ripening completed during the handling process. When fully ripe the cheese is soft and buttery in consistency and has a mild but characteristic flavour which becomes strong or ammoniacal when over-ripe. The ripe cheese has an optimum composition of water 47 to 49%, fat 25 to 28%, protein 18 to 21% and salt 2.2 to 2.8%. Variations from the figures while common quickly lead to lowered quality.

Cheddar Cheese takes its name from the Somerset village of that name where it was first made. It is now made not only in all parts of Great Britain but also in Canada, the United States and New Zealand. One reason for its widespread popularity is that the process by which it is made was the first to be reduced to a regular

system. Other kinds of cheese were, and in some cases still are, made by more or less haphazard methods dependent for their success on the personal skill and intelligence of the maker. The Cheddar cheese-making system was developed by the Somerset makers on precise lines which might be described as scientific, except that they were laid down by practical men before the chemist and bacteriologist had come to justify their empirical methods.

A description of the Cheddar system illustrates the general principles of cheese-making and the following detailed account given by Dr. Fream may be quoted. The successive operations are numbered consecutively—

1. It is usual to work up the morning's milk with that obtained overnight. The night's milk is cooled to about 60° F and then poured into the milk tub, care being taken to stir it occasionally to prevent the cream from rising.

2. In the morning heat the old milk so that it may be of the same temperature as the new milk to be mixed with it; this will be about 80° F. Stir it so that the cream may be broken.

3. Turn on steam so that the temperature may be raised to 82° F. It must be remembered that milk varies considerably according to the breed of cows from which it is obtained, the nature of the pastures on which the cows are fed, the weather and the time of year. Consequently temperatures at which the milk produced on different farms attain the proper degree of acidity during the various processes cannot be definitely fixed until the cheese-maker has had actual experience with the milk. This renders cheese-making by rule of thumb very difficult. When the milk has been raised to about 82° F in warm weather and to 85° F in cold weather add about one teaspoonful of rennet for each six gallons of milk in the tub, stirring the milk all the time, and continuing to stir for about 10 minutes. The bowl is used for stirring. Cover the tub with a thick cloth to retain warmth.

4. After coagulation the milk is left for about twice the length of time it took to coagulate, when the curd will be sufficiently formed to be broken. The stage for this operation is usually determined by leaving the bowl on the milk at the time the rennet is added; when the bowl will lift out clearly, with no curd attached, the curd is fit for cutting. This is done by means of the curd cutter, a long knife which is drawn through the curd so as to make parallel sections about 2 in. apart, and then used in a similar manner to make fresh sections at right angles to the former. Next break with the curd breaker; this is done steadily and continued until the curd is thoroughly broken, when it is allowed to settle. If steam is not available on the premises the temperature for the scaldings is raised by taking off and heating up a portion of the whey, and pouring it back into the tub until the whole has attained the desired temperature. The whey for the first scalding is taken from the tub as soon as the curd has settled and is heated up to about 130° F in readiness to scald. Whether scalded by steam or by heated whey the temperature in the cheese tub for the first scalding should be about 84° F to 86° F. Stir and allow the mass to lie for about 10 minutes, then raise the temperature to from 92° F to 102° F for the second scalding according to conditions. This is a wide margin, and a temperature of from 94° to 97° is generally found correct. Stir for about 10 minutes.

5. Allow the curd to "cook" in the whey for about half an hour keeping the tub covered with a cloth. Then draw off the whey. As soon as the curd becomes isolated, note the condition as to firmness and acidity, as this serves as a guide to the length of time during which exposure in the cooler may be necessary.

6. The whey having been drawn off, cut the curd into blocks about 8 in. square, and bring the lumps from the outside to the middle, so as to form a heap there. Then cover with cloths to keep in the warmth while the curd is becoming firm. Some makers place a weighted board on the top of the heap.

7. Take out the lumps and cut them into thin slices, and place them in a heap in the cooler, covering them with cloths. These slices must be turned occasionally to allow the ripening to proceed evenly throughout. The ripening is denoted by the touch, smell and appearance of the curd and it may occupy from two to four hours.

8. When ripened pass the curd through the curd-mill to reduce it to small pieces. After milling stir it gently with the hands for about 10 minutes, lifting it high in the air and allowing it to fall through the fingers.

9. Add 2½ lb. of salt per cwt. of curd, or 1 lb. of salt per 56 gal. of milk. Stir in well and then allow to remain about 20 minutes so that the salt may penetrate. Then place the curd in the vat, previously lined with a cloth, and put in the press.

10. On the first morning after vatting turn out the cheese, remove the cloth, and substitute a calico cloth and again put it into the press. On the second morning remove the cloth and encase the cheese in thin calico; some makers grease the cheese. On the third morning lace on a stout bandage and take the cheese to the loft or cheese-room.

11. The cheese will require turning daily at first, especially in hot weather. After about a fortnight twice a week is sufficient and at the end of a month once a week is often enough. The temperature of the cheese-loft should be maintained at 65° to 70°.

Cheshire cheese has a reputation older than that of Cheddar but its manufacture was not systematized at so early a period nor has it obtained the same cosmopolitan vogue. It ranks high in quality when made under the best conditions and it is claimed that these are obtained on the saline pastures of its native county. It is also made extensively in the adjoining counties of Stafford and Salop.

Club Cheese is made from selected Cheddar, ground through power grinders (meat grinders are commonly used). For this purpose blends of several lots of cheese with or without the addition of butter, pimento, olive or other flavour, are usually made to insure uniformity of texture and flavour. The cheese commonly passes through two grinding machines to secure smoothness of texture. The cheese passes into a stuffing machine which delivers it in cylindrical form so that it can be cut and wrapped in paper and tin-foil. The finished product is smooth, readily spread upon bread and attractive in flavour. It must be kept under refrigeration in the marketing process.

Canned Cheese.—The next step beyond the manufacture of club cheese involves the packing of the same product in tin containers for sterilization. Under most of the patents used some "emulsifier" is acknowledged as necessary to prevent the separation of the butter fat during cooking.

Cottage Cheese is the soft product made by souring skimmed milk under natural conditions in the home. When firmly coagulated the curd should be smooth, free from gas bubbles, with little or no extruded whey. At this point the container is placed in a vessel of water, stirred and slowly heated to a temperature varying from 90° to 120° F or much higher according to the hardness of the curd particles desired; it is then drained in bags until the whey ceases to run, kneaded with salt with or without the addition of cream, butter or other flavouring substance, after which it is ready to serve. It usually contains about 70% moisture and should have a clean, lactic acid or sour milk flavour.

Limburger Cheese takes its name from the town of Limburg in Belgium, but is widely manufactured in countries of northern Europe and in various sections of the United States. It is made from cow's milk either freshly drawn and still warm or reheated to 94° or 96° F, then curdled with rennet. The curd is cut, partially drained, then dipped into forms 5 in. square and 8 in. deep and allowed to drain by gravity. The newly made cheeses are turned several times to obtain even drainage and firm flat sides. They are then salted upon the surface and when firm enough are placed upon shelves in curing rooms where they are ripened at 58° to 64° F at a relative humidity of about 95%. During the ripening period they are rubbed and washed several times in salt water, then wrapped and packed into boxes for cool storage or shipment. When ripe, Limburger is smooth in texture, becomes almost buttery in consistency and has a strong, penetrating odour. Most Limburger is consumed when only partially ripe and sliced as a sandwich cheese.

Loaf Cheese; Pasteurized.—Since 1920, a whole series of pasteurized cheese varieties have appeared mostly in various patented processes for cutting cheese into cubes, mixing cubes from different sources to secure the desired blend of texture, colour and flavour, then melting the mixture in steamjacketed kettles fitted with mechanical stirring apparatus. As a rule water is added, together with some "emulsifier," which prevents the separation of fat during the heating process. While not usually sterilized these products are commonly well-pasteurized by the cooking given. When the process is complete the cheese is run into rectangular boxes varying in size from a few ounces each to five pounds, cooled, and handled under refrigeration. The products are usually mild in flavour, smooth and buttery in consistency. In less than ten years, the volume of production has risen from experimental samples to more than 100,000,000 lb. in the United States alone. Cheddar and Swiss constitute the larger part of this total although many varieties are packed.

Neuchatel.—The ripened Neuchatel cheese of France is made preferably from whole milk, curdled by a combination of rennet and souring, formed into cylindrical masses about two inches in diameter and three inches long, salted on the outside,

and ripened on mats in moist cool rooms. In its ripe condition it varies greatly with the factory and standards of the maker. Sometimes it is sticky, slimy and yellowish or reddish on the surface from the growth of the mould known as *Oidium* (or *Oospora*) *lactis* and bacteria; again it shows a firm mouldy rind from the growth of the Camembert mould (*Penicillium camemberti* of Thom), or its nearly related white form *P. Caseicolum* of Bainier. These cheeses are largely used in France and exported to some extent to England and other West European countries.

American.—A variety of Neuchatel is made extensively in the United States. The milk is curdled very slowly, commonly over night by a combination of a culture of lactic bacteria and a small amount of rennet; the curdled mass is then drained in bags, chilled, kneaded and moulded by machinery into characteristic shapes, usually cylindrical, and weighing three to four ounces. Each cake is wrapped in parchment paper or some type of tinfoil and sold for consumption fresh. Neuchatel must be eaten whilst fresh or kept in a refrigerator as it quickly loses its clean sourmilk flavour.

Stilton Cheese is the only kind made with double cream, *i.e.*, the cream from one milking is added to the whole milk of the next (*see* CHEESE). The afternoon milk is put into shallow pans and skimmed in the morning, the cream being mixed with the morning's milk. Sufficient rennet is used to cause coagulation in about an hour. The curd is slightly broken and put into cloths, the corners of which are drawn tightly together to press out the whey. When the curd is firm enough it is broken into smaller pieces and put into hoops in layers, with a little salt between the layers. The hoops are turned two or three times a day and when the cheese is firm enough it is taken out, bound up in a cloth, which is changed from time to time for a dry one, until the coat, or "rind" begins to form and the cheese is put in the curing room. The whey drains out and the curd becomes more or less acid and the characteristic blue mould in due time forms. Unfortunately the practice of making stilton of "single cream" milk has become common and the high reputation it once held as the premier English cheese has almost gone.

Swiss Cheese.—A variety of cheese originating in the Alpine Cantons of Switzerland, this cheese has been exported on a considerable scale to Germany, France, England and the United States. Swiss dairy men emigrating from their mountain home have carried the process of making this cheese into Germany, eastern France, Denmark, into New York, Pennsylvania and Wisconsin in the United States. Many years of investigation by the U.S. Department of Agriculture have brought the making and ripening process of Swiss cheese from a "rule of thumb" basis to a fairly well controlled procedure. The Swiss process as followed in the factories calls for cow's milk delivered warm (92° to 96° F) usually twice each day and curdled at once with rennet. In the original process no bacterial starter was used. The American investigations have shown the advantages from the introduction of a starter made with the *Lactobacillus bulgaricus*. When the milk was firmly curdled, the Swiss-maker broke or comminuted his curd with a tool known as the Swiss harp sufficiently roughly to insure the loss of part of the fat in the whey, thus producing a mass in which the casein more nearly equals the fat in quantity than in normal milk. This reduction is accomplished in the American Swiss process by separating part of the milk used. After the curd is cut and stirred for a time, the mass is heated with stirring continued, reaching a temperature from 128° to 135° F in 30 to 40 minutes. The excess of moisture in Swiss curd is thus expelled by the heat and stirring without the acidification characteristic of the Cheddar group. The curd when sufficiently firm is removed to the hoop and pressed. It is given about 24 hours in the hoop during which it is turned several times, acquires a firm rind, and cools sufficiently to hold its shape. The cheeses are then immersed in brine three to five days for salting after which they are placed in a room at about 70° F in which the typical fermentation produces gas holes or "eyes" due to the development of certain anaerobic bacteria, during a period of about two weeks.

The original makers depended upon the presence of the neces-

sary bacteria in the milk used but these bacteria appeared to be absent in some American milk supplies, hence a starter has been developed to introduce the necessary forms. While still more or less experimental, these results clearly point to practical control of this complicated fermentation by the use of the proper bacterial starters. When eye development is accomplished, Swiss cheese is transferred to a room at 60° F to slow down the activities of the ripening bacteria. In this room humidity is kept fairly high to prevent shrinkage. Ripening to satisfactory flavour requires several months. Often the Swiss makers use about ten months. The finished product appears in the market as very large round cheeses 6 to 8 in. thick, uncoloured, with the cut surface showing "eyes" $\frac{1}{2}$ in. or more in diameter. The cheese has a sweetish taste and a mild odour.

CHEESE DISHES

The recipes given below are useful either for lunch dishes or savouries.

Cheese Straws and Biscuits (hot or cold).—Roll the paste out thin, then cut into a strip $3\frac{1}{2}$ to 4 in. wide and not quite so long as the tin in which it will be baked. Lay it in the tin and with a sharp knife divide it into separate thin straws. Bake in a moderate oven until crisp and golden. From the trimmings cut out rings and small biscuits. The straws may be served plain or several put through a ring; the biscuits plain or made into a fancy savoury.

Cheese Creams (cold).—Pile on each biscuit some whipped cream well flavoured with grated cheese and cayenne or paprika: dust each with paprika.

Cheese Tartlets (hot).—Fit the pastry into tartlet tins and make a neat edge. Prick the bottom. Fill with small beans which may be used over and over again, provided they are allowed to become cold before putting away for future use. Bake in a moderate oven. Fill with flaked cooked fish (or finely minced cooked chicken or veal with ham or tongue) mixed into any well-flavoured sauce. Dust with fine browned bread crumbs and make hot.

Cheese Tartlets (cold).—Make the tartlet cases as before. Bake in a moderate oven about ten minutes. When cold fill with whipped cream mixed with grated cheese and seasoning and ornament with tomato or a few capers; or fill with a Russian salad, that is, tiny cubes of all sorts of cooked vegetables and some peas mixed into mayonnaise sauce. (For Cheese Pastry see PASTRY: *Homemade*.)

Cream of Cheese.—Prepare some rather thick slices of toast, cut into fingers. Arrange some of them in a fireproof soufflé dish and pour a liberal quantity of cream over. Strew thickly with grated cheese and season highly with pepper and salt. Then add a second and a third layer of toast, cream, cheese and flavouring, ending with a rather larger quantity of cream and cheese. Place the dish in a tin of hot water, cover with a tin or sheet of greased paper, and bake in a moderate oven for about ten minutes.

Macaroni Cheese.—Drain 4 oz. cooked macaroni and cut it into short lengths. Melt 1 oz. of butter in a pan, add one teaspoonful of made mustard and 1 oz. flour and blend well. Stir in gradually $\frac{1}{2}$ pt. of milk and continue to stir until boiling, then add the macaroni, 3 oz. of cheese and season well. When thoroughly well mixed, put into a greased fireproof dish, sprinkle 1 oz. of cheese and some bread crumbs over the top. Melt $\frac{1}{2}$ oz. of butter, pour it over and brown in the oven or under a gas grill.

To boil the macaroni put it into a pan of boiling salted water and boil without a lid on the pan for 30 to 40 m. or until the macaroni feels soft.

Cheese Soufflé (hot).—Melt $\frac{3}{4}$ oz. butter in a pan and then stir in $\frac{1}{2}$ oz. of sifted flour. Add by degrees $\frac{1}{4}$ pt. of warm milk, and stir till the mixture thickens; season with salt, pepper and cayenne and remove from the fire. When the mixture has cooled a little, add the yolks of two eggs, one at a time, then stir in 3 oz. of grated cheese, and very lightly mix in the whites of three eggs, previously whisked to a very stiff froth. Pour at once into a buttered soufflé dish and bake in a fairly quick oven for from 20 to 30 minutes. If the oven is too quick the soufflé is drawn up

too rapidly which leaves the middle not cooked enough and it falls more quickly when taken out of the oven.

Toasted Cheese.—Have ready some toast cut into neat squares or fingers. Melt 1 oz. butter in a stewpan, add a little evaporated milk, cream or thin white sauce and 6 oz. dry Cheddar cheese cut up very small: stir until melted, add $\frac{1}{2}$ teaspoonful made mustard, salt and pepper and, gradually, enough milk to make the mixture of the consistency of thick custard. Stir well, pour the cheese mixture on to the toast and serve very hot. The reason for using cream, evaporated milk or sauce is that some cheese when added to milk goes thin and curdles.

A variation of this dish consists of one-third of the quantity of cheese, the remainder of very fine bread crumbs and enough milk to make the consistency of the cooked mixture like an extremely thick custard. Pile on the toast and put under the grill or in the oven just to brown the top lightly.

Cheese Aigrettes (hot).—Boil 1 gill of water and 1 oz. margarine together in a pan, add 3 oz. flour all at once and quickly stir it well in. Cook for about 2 m. only or until the mixture has become a firm ball which does not stick to the pan at all. Let it cool a little, then beat in very well 2 eggs, one at a time, keeping the mixture quite stiff, then add $1\frac{1}{2}$ oz. grated cheese, salt and cayenne. Fry in deep fat, dropping in large teaspoonfuls of the mixture, not one at a time but continually. The fat must be moderately hot: if too smoking hot the outside will brown at once leaving the inside soft and pappy. The aigrettes should take 4 or 5 m. to fry and they should swell out well, be golden brown and cooked right through. Pile them on a napkin and sprinkle with grated cheese. Always dip the spoon into the fat before using it. (D. C. P.E.)

CHEETA, CHEETAH, CHITA or HUNTING-LEOPARD (*Cynaelurus jubatus*), a member of the family *Felidae*, distinguished by its claws being only partially retractile (see CARNIVORA). The cheeta attains a length of 3 to 4 ft.; it is of a pale fulvous colour, marked with numerous spots of black on the upper surface and sides, and is nearly white beneath. The fur is crisp, lacking the sleekness which characterizes the typical cats, and the tail is long and bushy at the tip. The cheeta is found throughout Africa and southern Asia, and has been employed for centuries in India and Persia in hunting antelopes and other game. It is taken to the field hooded and chained in a low car without sides. When the game is sufficiently near (within about 200 yards), the cheeta is loosed and proceeds to stalk its prey, finishing with a few gigantic bounds. In India the name cheeta is applied also to the leopard.

BY COURTESY OF THE N. Y. ZOOLOGICAL SOCIETY.
THE CHEETA, OR HUNTING LEOPARD

CHEF, in French, a chief or head person; in English-speaking usage, the head-cook in a club or large private establishment, or the head of the kitchen department in a large hotel or commercial catering organization. In general a chef is responsible for the conduct and operation of the food preparation in a large kitchen. He directs the staff of cooks, bakers and others required to prepare food for serving. He plans meals, prepares menus and sees that sanitary practices are observed. If a chef-steward, he may be given complete control of kitchen, pantries and ice-boxes including all purchasing, and be expected to figure prices. If only a supervising chef, he is only responsible for the preparation of the food supplied to him from the stores department on requisition. He is usually expected to be able to devise new recipes for preparing foods and more attractive ways for arranging them for service.

Every establishment preparing food on a large scale usually has a chef in charge of cooking operations. The constant growth of the hotel business and the commercial preparation of foods gives employment each year to a still larger number of chefs, though the requirements tend to become greater due to the demand for men having a more thorough knowledge of nutrition and food chemistry. For the most part, chefs are a product of an apprentice system. Young men start as assistant vegetable

man, or even lower in the culinary scale, pass through a long line of specialized cooking positions such as vegetable cook, fry cook, roast cook (*rossetier*), roundsman, at times as baker or butcher, pastry man, cold meat chef (*garde manger*), until finally they become chefs, a process requiring from 4 to 8 years and frequent changes of employment. Schools for chefs and cooks are practically non-existent in the U.S.A., though not unknown in Great Britain. The leading chefs in English-speaking countries have usually served an apprenticeship in central Europe or in France, whence they depart after completing their service. In some commercial establishments trained chemists and graduates from university schools of home economics often serve as chefs, though usually under a different title.

CHEFOO, a treaty port on the rocky north coast of the Shantung peninsula in north-east China (37° 33' N., 121° 22' E). The port is naturally sheltered by outlying islands and in recent years these have been linked up by breakwaters to form a fully protected harbour. The port is more properly Yentai, Chefoo being a village across the harbour. Population (estimated) 94,700. The tangled hill country of Shantung rises immediately behind Chefoo and its communications with the interior are only by pack-mule trails. A branch line of the Tsingtao-Tsinan railway to Chefoo is projected. Chefoo was opened to foreign trade in 1863. Since 1907 the trade of Chefoo has remained consistently at just over Hk. Tls. 30,000,000 (Hk. Tls. 34,335,785 in 1926). Similarly, Chefoo retained among Chinese ports the 10th place until 1907, since when it has fallen to the 18th. It is the market for the tussore silk industry of the Shantung hills and raw silk constitutes its staple export. In general agricultural produce, however, the main volume of the export trade from hilly Shantung passes through Kiaochow on the south side of the peninsula. Across the Gulf of Pechihli the peninsula of Shantung faces the very similar peninsula of Liaotung and between Chefoo, on the Shantung, and Antung, on the Liaotung side, a considerable trade has grown up, especially in silk, which each peninsula produces and each port manufactures. In this direction, however, it appears that Antung is growing at the expense of Chefoo.

CHEHALIS, a city of Washington, U.S.A., 25m. S. by W. of Olympia, 4m. S. of Centralia (*q.v.*); the county seat of Lewis county. It is on Federal highway 99, and is served by the four trans-Continental railways which serve Centralia, and also by the Cowlitz, Chehalis and Cascade railway. Its manufacturing industries include saw and shingle mills, brick and tile works, a cannery, a creamery and condensed-milk plants. The population in 1930 was 4,907.

CHEKE, SIR JOHN (1514-1557), English classical scholar, was one of the founders of Greek learning at Oxford. At St. John's college, Cambridge, where he became a fellow in 1529, he adopted the principles of the Reformation. In 1540, on Henry VIII's foundation of the regius professorships, he was elected to the chair of Greek. In a letter on the state of Greek learning at Cambridge to a fellow of St. John's college, Oxford, in 1542, his pupil, Roger Ascham, describes how Demosthenes had become as familiar as Cicero, and that Herodotus, Thucydides and Xenophon were more connd than Livy was in his student days. With Sir Thomas Smith, who shares with him the major part of the credit for the establishment of Greek studies at Cambridge, he introduced the "Erasmian" pronunciation of Greek in his lectures, rejecting the Italian and modern Greek method of giving various vowels and diphthongs the same sound, which the first western students had learned from Greek and Italian humanists. It was strenuously opposed in the university, where the "Reuchlinian" method favoured by Melancthon prevailed, and Bishop Gardiner, as chancellor, issued a decree against it (June 1542); but Cheke ultimately triumphed. On July 10, 1554, he was chosen tutor to Prince Edward, who retained him in that capacity after his accession to the throne. Cheke sat, as member for Bletchingly, for the parliaments in 1547 and 1552-1553; he was made provost of King's college, Cambridge (April 1, 1548), was one of the commissioners for visiting that university as well as Oxford and Eton, and was appointed with seven divines to draw up a body of laws for the governance of

the church. On Oct. 11, 1551, he was knighted; in 1553 he was made one of the secretaries of State, and sworn of the privy council. He filled the office of secretary of State for Lady Jane Grey during her nine days' reign. In consequence Mary threw him into the Tower (July 27, 1553), and confiscated his wealth. He was released on Sept. 13, 1554, and granted permission to travel abroad. He went first to Basle, then visited Italy, giving lectures in Greek at Padua, and finally settled at Strasbourg, teaching Greek for his living. In the spring of 1556 he visited Brussels to see his wife; on his way back, between Brussels and Antwerp, he and Sir Peter Carew were treacherously seized (May 15) by order of Philip of Spain, hurried over to England, and imprisoned in the Tower. Cheke was terrified by a threat of the stake, and giving way, was received into the Church of Rome by Cardinal Pole, being cruelly forced to make two public recantations. He died in London on Sept. 13, 1557.

Thomas Wilson, in the epistle prefixed to his translation of the Olynthiacs of Demosthenes (1570), has a long and most interesting eulogy of Cheke; and Thomas Nash, in *To the Gentlemen Students*, prefixed to Robert Greene's *Menaphon* (1589), calls him "the Exchequer of eloquence, Sir Ihon Cheke, a man of men, supernaturally traded in all tongues." Many of Cheke's works are still in ms., some have been lost altogether. One of the most interesting from an historical point of view is the *Hurt of Sedition how greuous it is to a Commonwealth* (1549), written on the occasion of Ket's rebellion, republished in 1569, 1576 and 1641, on the last occasion with a life of the author by Gerard Langbaine. Others are *D. Joannis Chrysostomi homiliae duae* (1543), *D. Joannis Chrysostomi de providentia Dei* (1545), *The Gospel according to St. Matthew . . . translated* (c. 1550; ed. James Goodwin, 1843), *De obitu Martini Bucer* (1551), (Leo VI.'s) *de Apparatu bellico* (Basel, 1554; but dedicated to Henry VIII., 1544), *Carmen Heroicum, aut epitaphium in Antonium Dencium* (1551), *De pronuntiatione Graecae . . . linguae* (Basel, 1555). He also translated several Greek works, and lectured admirably upon Demosthenes.

His *Life* was written by John Strype (London 1705, Oxford 1821); additions by J. Gough Nichols in *Archaeologia* (1860), xxxviii. 98, 127.

CHEKHOV, ANTON PAVLOVICH (1860-1904), Russian dramatist and story-writer, born on Jan. 17, 1860, in Taganrog on the Sea of Azov. This name is also spelled Tchekhov, Tchekov and Chehov. His father was a tradesman and the son of a serf. The writer was educated at the *gymnasium* of his native town, and in 1879 went to the University of Moscow, where he studied medicine. He took his degree in 1884 but practised very little (except during the cholera epidemic of 1892-93). He began his literary career while yet a student, and soon became one of the most welcome contributors to the comic papers. His early stories appeared over the signature Antosha Chekhonte. In 1886 some of his stories were published in book form (*Particoloured Stories*). The book had a great success and attracted the attention of the publisher and editor Suvorin, who became his friend.

In 1887 he produced his first play *Ivanov*. In 1890 he travelled to the convict island of Sakhalin and the result of his journey was *Saghalien Island* (1891), which had a considerable effect on the mitigation of the penal régime. From 1891 to 1897 he lived with his parents on a small estate he had acquired not far from Moscow. After 1897, as he was threatened with tuberculosis, he was forced to live the greater part of the year in the Crimea and abroad. In 1896 he produced his second play, *The Seagull*, which was a complete failure in St. Petersburg (Leningrad). But in 1898 it was revived by the Moscow Art theatre of Stanislavsky and proved a great success. Henceforward Chekhov's connection with that theatre became very close. *Uncle Vanya* (1899), *The Three Sisters* (1901) and *The Cherry Orchard* (1904) were produced there. In 1901 he married the actress Olga Knipper. In 1900 he was elected an honorary fellow of the Academy of Science, but resigned his fellowship when the election of Maxim Gorky was cancelled by the Government. He died on July 2, 1904, at Badenweiler in the Black Forest.

Early Work.—The early stories of Chekhov, up to about 1886, are chiefly humorous. They are, in Russia, the most widely popular part of his work, and more people know him by them than by *My Life* or *The Three Sisters*. Chekhov's humour is not strikingly above the level of the papers he wrote for. But very early he began to lay the foundations of that manner which is the essential Chekhov. Such a story as *The Chorus Girl* (1884) is almost

a mature masterpiece. It was, however, only after 1886 that he found the necessary leisure and independence to give definite expression to his imaginative experience. The years 1886-88 are a period of transition during which he experimented in various directions. To these years belong a series of stories of atmosphere against a background of nature (*The Steppe*, *Happiness*, *Easter Eve*) where the lyrical element of his genius received its fullest expression, and short stories of morbid experience in which the knowledge of the doctor is balanced by the sense of form of the artist. By 1889, however, he had attained perfection in his style. To this and the following years belong a succession of masterpieces, the principal of which are *A Dreary Story* (1889), *The Duel*, *Ward No. 6* (1892), *The Teacher of Literature* (1894), *Three Years: An Artist's Story*, in Russian *The House with the Maisonet* (1895), *Peasants* (1897), *The Darling*, *Ionitch*, *The Lady with the Dog* (1898), *The New Villa* (1899), *The Bishop* (1902).

Chekhov's art has been described as psychological, but his psychology ignores the individual. His characters are not persons but just men and women, the genus *homo*, an indifferentiated mass of humanity, divided into watertight compartments by the phenomenon of individuality, which does not make one being different from another but only inaccessible to him. A typical story by Chekhov is the life-story of a "mood," of a state of mind, usually of the relation of one person to another and the gradual transformation of that state of mind under the action of the incessant infinitesimal and unforeseen pinpricks of life. Sensitiveness to these pinpricks is the main feature of Chekhov's people, of those at least who are made to kindle the reader's sympathy, and the standard by which Chekhov gauges the worth of a human being. Those who suffer and succumb are the higher race, those who do not are unfeeling brutes. Hence a deep-rooted aversion (present in pre-Chekhov Russian literature, especially in Turgenev, but enormously magnified by Chekhov) for the strong and efficient man. None but "Hamlets" may receive sympathy.

The construction of Chekhov's stories may be described as musical or infinitesimal. It is at once fluid and precise. They are built along exactly calculated curves, of which only certain points are marked in the story, but each two points are sufficient to calculate the whole curve. The curve is the mood which begins as almost a straight line, then under the influence of "pinpricks" begins to deviate and at last shoots out in an entirely opposite direction. By far the greater number of Chekhov's stories end on a minor note, "not with a bang but a whimper." A story where the direction is in the opposite way, as in *The Lady with the Dog* (where the hero begins by regarding his love for the lady as a mere insignificant intrigue and ends in self-forgetful passion), is an exception. The "pessimistic," destructive, descendant tendency of the Russian novelists of the mid and later 19th century reaches its extreme expression in Chekhov, all the more extreme as it is so consistently muffled and "understated." To him, better than to anyone, the words of Albert Thibaudet apply, that a Russian story is always the story of the undoing of a life.

Somewhat apart from the other stories of Chekhov stand, what are perhaps his two masterpieces, *My Life* (1895) and *In the Ravine* (1900). They have a clearer and harder outline; they are free from the atmospheric, autumnal haze that pervades the others, and animated by a more active sense of moral and human values. *My Life*, especially, is a creation of vast and pregnant significance, with a symbolical grasp that gives it an almost religious character.

Chekhov's dramatic work consists of the same element as his narrative work. It includes numerous one-act plays which were extremely popular in Russia. Belonging to a later period than the comic stories, they are also on a higher artistic level. The serious plays are five in number—*Ivanov*, *The Seagull*, *Uncle Vanya*, *The Three Sisters*, *The Cherry Orchard*. They have many points in common with his stories; one main difference is that while the stories invariably centre round a single person from whose standpoint the situation is developed, the dramas have no such central figure, and all the characters have more or less equal rights on the stage. The plays are, as it were, symphonies for an orchestra of

parts, and the resultant is arrived at by the complex interaction of the various voices. They are plays of "atmosphere," the English word that comes nearest to the Russian *nastroenie* (Stimmung). The principal thing in them is not the action but the emotional accompaniment of the action. In the "de-theatricalisation" of the theatre, in the complete avoidance of all traditional stage effects (though he introduced a new kind of "atmospheric" effect, as the famous string bursting at the end of *The Cherry Orchard*), Chekhov is the logical limit of the preceding development of the Russian drama. He did not go much further in this respect than Turgenev or Ostrovsky, but he built a more consistent dramatic system with a completely adequate technique.

The Novelist's Influence.—The influence of Chekhov on Russian literature has not been extensive. The last realists (Andreyev, Gorky, Bunin, etc.) learned little from him, and soon after his death the rise of an entirely new movement put an end to all possibility of continuing in his tradition. His plays were imitated by Gorky, Andreyev and others, but they invariably missed the constructive principle without which the whole system is stultified. To the Russia of to-day Chekhov is perhaps more alien than any other Russian writer of his rank.

On the other hand, his vogue and his influence outside Russia have of recent years grown immensely and were in 1927 probably near their zenith. England has proved particularly sensitive to his charm. He is almost universally regarded as the greatest Russian writer and as the greatest story-teller and dramatist of modern times.

(D. S. M.)

CHEKIANG, the smallest but one of the most famous and densely peopled provinces of China, with an area of 36,680 sq.m. and a population of 22 millions. It is the most northerly of the coastal provinces of south China and is situated where the south-west to north-east ridges, so characteristic of south-east China, begin to sink beneath the alluvial plains of the delta of the Yangtze-Kiang. The province, indeed, falls naturally into two physiographic regions demarcated by the Tayu-ling, the northernmost ridge, which runs out to sea in the Chusan archipelago. The southern region consists of ridges and troughs parallel to the Tayu-ling and cut across by a number of transverse rivers. At the mouth of the largest of these, the Wu-kiang, lies Wenchow, the chief port of southern Chekiang. The northern region, drained for the most part by a single river, the Tsien-tang, with its outlet in Hangchow bay, consists essentially of the alluvial plains round the bay and of the foothills of the highlands. These northern plains are the most densely peopled part of the province participating in the life of the Yangtze delta and containing the well-known seaport of Ningpo and the far-famed and beautiful capital city of Hangchow. This northern part of the province therefore resembles southern Kiangsu, while the rest is essentially similar to Fukien, which succeeds it on the south. Away from the plains around Hangchow bay flat land is rare and terraces stretch far up the mountain slopes.

The crops—wheat and beans, rice and cotton, tea and silk—are typical of mid-China, where the products characteristic of north and south overlap. On the slopes of the maritime ranges, scenically one of the most beautiful parts of China, some of the best tea grown in the country is produced. The historical rôle of the province and many aspects of its culture reflect the pivotal position of Chekiang. Before the consolidation of China in the 3rd century B.C. north Chekiang was the core of the maritime state of Yüeh, which finally gained the mastery over the whole Yangtze delta. During the 12th and 13th centuries A.D. it had a

larger significance, for Hangchow was then the capital of what remained of China to the Sung dynasty, retreating southwards before the Kin Tatars, and, after the Mongol conquest, it remained the acknowledged centre of Mangi. (See CATHAY.)

The province has played a conspicuous part in the cultural history of China and in recent times is said to have produced much the highest proportion, relative to its population, of *literati* and officials of high rank. Linguistically, Chekiang belongs to the non-Mandarin speaking zone of south-east China. Over by far the greatest part of the province the Wu dialects, spoken in southern Kiangsu, prevail, and this constitutes another link with the Yangtze delta and facilitates close economic connection. In the south-west, Mandarin (or the official language) from Kiangsi and the Fukien dialects transgress the provincial boundary.

CHELLEAN, the name given by the French anthropologist G. de Mortillet to the first epoch of the Quaternary period when the earliest human remains are discoverable. The word is derived from the French town Chelles in the department of Seine-et-Marne. The Chellean epoch was interglacial, warm and humid as evidenced by the wild growth of fig-trees and laurels. The animals characteristic of the epoch are the *Elephas antiquus*, the rhinoceros, the cave-bear, the hippopotamus and the striped hyaena. Man existed and belonged to the Neanderthal type. The implements characteristic of the period are flints chipped into leaf-shaped forms and held in the hand when used. There is clear evidence of phases of Chellean industry—both in a simple and an advanced stage.

See Gabriel de Mortillet, *Le Préhistorique* (1900); M. C. Burkitt, *Prehistory* (1925); H. Peake and H. J. Fleure, *Ages and Men* (1927).

CHELM (Russian *Kholm*), a town of Poland, in the province of Lublin, 45m. by rail E.S.E. of the city of Lublin. It was founded in 1223 by Prince Daniel of Volhynia. Here the Russian Government suppressed the Uniate Church in the 19th century.

CHELMNO (German *Kulm*), a small town of Poland, in the province of Pomorze (Pomerania), 11m. E. of the Vistula. It is surrounded by 13th century walls, and contains some interesting churches, two Roman Catholic and two Protestant, and a mediaeval town-hall. There are large oil mills and an important trade in agricultural produce, including fruit and vegetables. Granted in 1226 by Conrad of Mazovia to the Teutonic Order, it became the base for their conquest of Prussia and the seat of the first Prussian bishopric. It always retained a large Polish population, which revolted against the Order and was re-annexed to Poland by the peace of Thorn in 1466. It was part of Prussia from 1773 to 1918. It was a prominent member of the Hanseatic League and used to carry on extensive manufactures of cloth.

CHELMSFORD, FREDERICK JOHN NAPIER THESIGER, 1ST VISCOUNT (1868—), British administrator, born on Aug. 12, 1868, was the eldest son of Frederick Augustus, 2nd Baron Chelmsford. He was educated at Winchester and Magdalen college, Oxford, and held a fellowship at All Souls from 1892 to 1899. Having been called to the bar he was a member of the London school board for four years, and in 1904–5 served on the London county council. In the latter year, when he succeeded his father as Baron Chelmsford, he was appointed governor of Queensland and he held that office till 1909. These years saw the inauguration of the new policy of replacing the repatriated Kanakas by white labour. It was also a period of bitter political conflict. Chelmsford's action in granting the request of the premier, Philp, for a dissolution of parliament led to widespread agitation for the appointment of local governors in Australia. In Aug. 1909 Chelmsford left Queensland for New South Wales, of which State he was governor till 1913. It was a period of great development for the colony, and also of great labour unrest.

Chelmsford, who was created G.C.M.G. in 1912, served in India with the Dorset regiment in the early part of the World War. From April 1916 to the spring of 1921 he was viceroy of India. During this period the system of dyarchy, founded upon the joint report of the viceroy and the secretary of State, E. S. Montagu, was introduced. A considerable measure of autonomy was accorded to the provinces. The council of State and legisla-

tive assembly were to be elected, and the annual budget, with some reservations, submitted to the latter. Indians were given representation on the viceroy's council, and India was given the same power over tariffs as the Dominions.

But the new reforms were opposed by a combination of Hindus and Muslims under Gandhi, and a system of non-co-operation adopted, whilst the repressive legislation recommended by Mr. Justice Rowlatt's committee to deal with sedition provoked serious riots in Guzerat and the Punjab, culminating in the Amritsar disturbances (April 1919). However, an amnesty for political offences accompanied the promulgation of the reforms which were gradually accepted by moderate opinion. Meanwhile the viceroy had also to meet a Mohammedan agitation directed against British policy toward Turkey. This was actively supported by an Afghan army, after whose defeat the subsidy was withdrawn from the Amir, together with the privilege of importing arms from India. The new institutions were inaugurated by the duke of Connaught early in 1921. On his retirement Chelmsford was created a viscount and received Indian orders. He was first lord of the admiralty in Ramsay MacDonald's Labour Ministry of 1924. (G. LE G. N.)

CHELMSFORD, FREDERIC THESIGER, 1ST BARON (1794–1878), lord chancellor of England, was the third son of Charles Thesiger, and was born in London on April 15, 1794. Young Frederic Thesiger was originally destined for a naval career, and he served as a midshipman on board the "Cambrian" frigate in 1807 at the second bombardment of Copenhagen. About this time he succeeded to a valuable estate in the West Indies, so he left the navy and studied law, with a view to practising in the West Indies, and eventually managing his property in person. But a volcano destroyed the family estate, and he was thrown back upon his prospect of a legal practice in the West Indies. He entered Gray's Inn in 1813, and was called on Nov. 18, 1818. Godfrey Sykes, whose pupil he was, advised him to try his fortunes in England. He accordingly joined the home circuit and practised at the Surrey sessions, also buying the right to appear at the old palace court (see LORD STEWARD).

In 1824 he distinguished himself by his defence of Joseph Hunt when on his trial at Hertford with John Thurtell for the murder of William Weare; and eight years later at Chelmsford assizes he won a hard-fought action in an ejectment case after three trials, to which he attributed so much of his subsequent success that when he was raised to the peerage he assumed the title Lord Chelmsford. In 1834 he was made king's counsel, and in 1835 was briefed in the Dublin election inquiry which unseated Daniel O'Connell. In 1840 he was elected M.P. for Woodstock. In 1844 he became solicitor-general, but having ceased to enjoy the favour of the duke of Marlborough, lost his seat for Woodstock and had to find another at Abingdon. In 1845 he became attorney-general, holding the post until the fall of the Peel administration on July 3, 1846. Thus by three days Thesiger missed being chief justice of the common pleas, for on July 6 Sir Nicholas Tindal died, and the seat on the bench, which would have been Thesiger's as of right, fell to the Liberal attorney-general, Sir Thomas Wilde. In 1852 he became M.P. for Stamford. On Lord Derby coming into office for the second time in 1858, Sir Frederic Thesiger was raised straight from the bar to the lord chancellorship (as were Lord Brougham, Lord Selborne, and Lord Halsbury). In the following year Lord Derby resigned. Again in 1866, on Lord Derby coming into office for the third time, Lord Chelmsford became lord chancellor for a short period. In 1868 Lord Derby retired, and Disraeli, who took his place as prime minister, wished for Lord Cairns as lord chancellor. Lord Chelmsford died in London on Oct. 5, 1878. He had married in 1822 Anna Maria Tinling, and left four sons and three daughters, of whom the eldest, Frederick Augustus, 2nd Baron Chelmsford (1827–1905), earned distinction as a soldier, while the third, Alfred Henry Thesiger (1838–80), was made a lord justice of appeal and a privy councillor in 1877, at the age of 39, but died only three years later.

See *Lives of the Chancellors* (1908), by J. B. Atlay, who had the advantage of access to an unpublished autobiography of Lord Chelmsford.

CHELMSFORD, market town and municipal borough, and the county town of Essex, England, 30 m. E.N.E. from London by the L.N.E.R. Pop. (1931) 26,537. It lies in the Chelmer valley at the confluence of the Cann, and has communication by river with Maldon and the Blackwater estuary 11 m. east. Chelmsford (*Chilmersford*, *Chelmeresford*, *Chelmesford*) owed its mediaeval importance to its position on the road from London to Colchester. It consisted of two manors: that of Moulsham, which remained in the possession of Westminster Abbey from Saxon times till the reign of Henry VIII. and that of Bishop's Hall, which was held by the bishops of London from the reign of Edward the Confessor to 1545. The mediaeval history of Chelmsford centred round the manor of Bishop's Hall. Early in the 12th century Bishop Maurice built the bridge over the Chelmer which brought the road from London directly through the town, thus making it an important stopping-place. The town was not incorporated until 1888. In 1225 Chelmsford was made the centre for the collection of fifteenths from the county of Essex, and in 1227 it became the regular seat of assizes and quarter-sessions. The parish church of St. Mary is a Perpendicular building, largely rebuilt. The grammar school was founded by Edward VI. In 1199 the bishop obtained the grant of a weekly market, and in 1201 that of an annual fair, now discontinued, for four days from the feast of St. Philip and St. James. The town has a large agricultural market and a corn exchange in the centre of the square. There are agricultural implement and iron foundries, electrical and engineering works and extensive corn mills. There is a race-course 2 m. south of the town. Chelmsford is the seat of a bishop. There is also a wireless transmitting station, where, Feb. 23, 1920, the first wireless telephone broadcasting service in the world was transmitted. The borough is in the Chelmsford parliamentary division of Essex. Area (of municipal borough) 3,112 acres.

CHELMSFORD, a town of Middlesex county, Massachusetts, U.S.A., in the north-eastern part of the State, adjoining the city of Lowell. It lies on both sides of the Concord river, and is served by the New York, New Haven and Hartford railroad. The population in 1930 was 7,022 Federal census. It has numerous factories. Chelmsford is first mentioned in the records of the State in 1655. Lowell was set off from it in 1826.

CHELSEA, a western metropolitan borough of London, England, bounded east by the city of Westminster, north-west by Kensington, south-west by Fulham, and south by the river Thames. Pop. (1931) 59,026. Its chief thoroughfare is Sloane street, running south from Knightsbridge to Sloane square. From Chelsea King's road leads west, a commercial highway, named in honour of Charles II. and recalling the private road from St. James's palace to Fulham. The main roads south join with the Victoria or Chelsea, Albert and Battersea bridges over the Thames. The Chelsea embankment, planted with trees and lined with fine houses and, in part, with public gardens, stretches between Victoria and Battersea bridges. The residential portion is eastern Chelsea near Sloane street and along the river.

Chelsea, especially the riverside district, has many historical associations. At *Cealchythe* a synod was held in 785. A similar name occurs in a Saxon charter of the 11th century and in Domesday; in the 16th century it is *Chelcith*. The later termination *ey* or *ea* was associated with the insular character of the land, and the prefix with a gravel bank (*ceosol*; cf. Chesil bank, Dorsetshire); but the early suffix *hythe* commonly means a haven. The manor was originally in the possession of Westminster Abbey, but its history is fragmentary until Tudor times. Henry VIII. passed it to his wife Catharine Parr. It fell afterwards to the Howards and the Cheynes, and later to the Cadogans. The memorials in St. Luke's (the old church) include those of Sir Thomas More (d. 1535); Lord Bray, lord of the manor (1539); Lady Jane Gwydeford (1555); Lord and Lady Dacre (1594-1595); Sir John Lawrence (1638); Lady Jane Cheyne (1698); Francis Thomas, "director of the china porcelain manufactory, Lawrence Street, Chelsea" (1770); Sir Hans Sloane (1753); Thomas Shadwell, poet laureate (1692); Woodfall, the printer of *Junius* (1844), and many others.

In the 18th and 19th centuries Chelsea was a literary and artistic quarter. Atterbury and Swift lived in Church lane, Steele and Smollett in Monmouth house. Later, the names of Turner, Rossetti, Whistler, Leigh Hunt, Carlyle (whose house in Cheyne row is preserved as a public memorial), Lord Courtney, Count D'Orsay and Isambard Brunel, are connected with Chelsea. At Lindsey House Count Zinzendorf established a Moravian Society (c. 1750). Sir Robert Walpole's residence was extant till 1810; and till 1824 the bishops of Winchester had a palace in Cheyne walk. Queen's house (Tudor house) was the home of D. G. Rossetti.

Ranelagh (*q.v.*) in the second half of the 18th century, and Cremorne gardens (*q.v.*) in the middle of the 19th, were famous places of entertainment. Don Saltero's museum contained curiosities from Sir Hans Sloane's famous collections. Sloane gave the Apothecaries' Company ground for the Physick garden, which ceased in 1902 to be maintained by the company. The original Chelsea bun-house, claiming royal patronage, stood until 1839, and one of its successors until 1888. The porcelain works existed for some 25 years before 1769, when they were sold and removed to Derby.

Chelsea Royal hospital for invalid soldiers, initiated by Charles II. and opened in 1694 is well known. A system of out-pensioning was found necessary from the outset, and it relieves large numbers throughout the empire. The picturesque building by Wren stands in extensive grounds, which include the former Ranelagh gardens. The duke of York's school was removed in 1909 to Dover. There are also the Whitelands and St. Mark's training colleges; the Victoria and the Cheyne hospitals for children, a cancer hospital, the south-western polytechnic, and a public library containing an excellent collection relative to local history.

The metropolitan borough of Chelsea returns one member to parliament.

CHELSEA, a city of Suffolk county, Massachusetts, U.S.A., on a peninsula between the Mystic and the Chelsea rivers, opposite the Charlestown and East Boston districts of the city of Boston, and bounded on the north by the city of Everett. It has 3m. of water-front on upper Boston bay; and is served by the Boston and Maine and the Boston and Albany railways. The population in 1920 was 43,184, of whom 17,198 were foreign-born white (10,042 from Russia and Poland); and in 1930 was 45,816 by the Federal census. The central part of the city has been practically rebuilt since 1908, when, on April 12, it was swept by a terrible fire. Chelsea is primarily an industrial city, with some 200 factories making products valued at over \$50,000,000 annually. Its leading industries are lithography, shipbuilding and manufactures of shoes, radio sets, car-wheels, rubber products, wall-paper, elastic webbing, boxes, marine clocks, creosote products, lamp black, shingle stains, whitening, structural iron and ornamental ironwork. It is a centre for junk salvage, with 145 dealers in many kinds of waste material. A U.S. naval hospital, a Marine hospital, local headquarters of the Lighthouse Division of the Department of Commerce, the Massachusetts Soldiers' Home are situated here. The assessed valuation of property in 1927 was \$54,799,600. Chelsea (called Winnisimmet until 1739) was settled in 1624 by Samuel Maverick, a prominent loyalist and churchman, the first settler on Noddle's island (East Boston) and one of the first slave-holders in the colony. It was set off from Boston as a separate town in 1739, and was chartered as a city in 1857. In May, 1775, a British schooner in the Mystic river was captured by colonial militia under Gen. John Stark and Israel Putnam.

CHELSEA HOSPITAL. The Royal Hospital, Chelsea, to give the institution its full title, was founded by Charles II. Tradition has it that Nell Gwynne moved the King to build the hospital, but it is probable that the idea originated with Sir Stephen Fox, who had been a Paymaster General to the Forces. Christopher Wren was the architect, and the building was completed in 1692. Many military trophies are preserved at the hospital, including the colours captured at Blenheim and Waterloo, and there is a fine collection of medals and pictures in the Great Hall.

The candidates for a Chelsea In-Pension must be Out-Pensioners, *i.e.* in receipt of either a service, disability or campaign pension. Candidates must be 55 years of age, unless through loss of limb or other disability, the result of army service, they are considered eligible for admission to In-Pension at an earlier date. The establishment of In-Pensioners is 558. The candidates must be capable of looking after themselves. In-Pensioners may leave the hospital and revert to Out-Pension if they so wish, but unless there are some exceptional reasons such men are not again admitted to In-Pension.

In addition to the In-Pension establishment, the Board of Commissioners administer long service pensions, special campaign pensions, and deal with disability pensions other than those arising from the World War and earlier wars, which are administered by the Ministry of Pensions. They also approve, after investigation, the applications of pensioners who desire to receive a commuted sum in lieu of a portion of pension for the purpose of house purchase, etc. The number of men on the Army Pension List administered by the Commissioners of the Royal Hospital was in 1927 approximately 103,000.

CHELTENHAM, a municipal and parliamentary borough and watering-place of Gloucestershire, England, with railway stations on the L.M.S. and G.W. railways. Pop. (1931) 49,385. The town is well situated in the valley of the Chelt, a small tributary of the Severn, under the high line of the Cotswold hills to the east.

Cheltenham (*Celtanhomme*, *Chiltham*, *Chelteham*), an early settlement, had a church in 803. The manor belonged to the crown; it was granted to Henry de Bohun, earl of Hereford, in the 12th century, but in 1199 was exchanged for other lands with the king. In 1252 the abbey of Fé camp purchased the manor, and it afterwards belonged to the priory of Cormeille, but was confiscated in 1415 as the possession of an alien priory, and was granted in 1461 to the abbey of Lyon, by which it was held until once more returning to the Crown at the Dissolution, it went to the family of Dutton. The town is first mentioned in 1223, when the benefit of the markets, fairs and hundred of Cheltenham was leased to the men of the town for three years; Henry III. renewed the lease in 1226, and in 1230 granted a Thursday market and a fair on the vigil, feast and morrow of St. James. A market town in the time of Camden, it was governed by commissioners from the 18th century till 1876, when it was incorporated. It became a parliamentary borough in 1832. After the discovery of mineral springs in 1716, and the erection of a pump-room in 1738, Cheltenham rapidly became fashionable, the visit of George III. and the royal princesses in 1788 ensuring its popularity.

The Montpellier and Pittville Springs supply handsome pump rooms in public gardens, and are the property of the corporation. The parish church of St. Mary is 14th century, but is almost completely modernized. The town, moreover, is wholly modern in appearance. A new town hall, including a central spa and assembly rooms, was opened in 1903. The free grammar school (1568) is the oldest local school. The public schools for boys (Cheltenham college 1842) and for girls (Ladies' college, Cheltenham, 1854) are very well known. A training college for teachers was founded 1846. The parliamentary borough, but not the municipal borough, includes Charlton Kings (pop. [1921] 4,379).

CHELYABINSK, a county and town in the Uralsk area of the Russian S.F.S.R. The county has an area of 27,680 sq. km. Pop. (1926) 496,072, entirely rural except for the town of Chelyabinsk. It is dotted with forest, marsh and lake, but 59.2% is under cultivation (wheat, oats, rye, millet, peas, etc.). Cattle, sheep, horses and pigs are reared and coal is mined, 200,000 tons being extracted in 1924-25, a total in excess of the pre-war production. There are flour mills, brandy distilleries, breweries and other factories for food products. The town of Chelyabinsk, lat. 55° 8' N., long. 61° 35' E., pop. (1926) 59,203, is an important trading centre for coal and Siberian grain. Manufactures of agricultural implements and leather goods are carried on, and the town has an elevator and a radio-station. It is connected by rail with the north through Sverdlovsk (formerly Ekaterinburg), with the east, as the beginning of the trans-Siberian railway, and with

the west through Zlatoust and Ufa. It was founded in 1658. During the Civil War following the 1917 revolution Chelyabinsk was for a time the headquarters of the Czechoslovak legion and the scene of much internecine warfare.

CHELYS, the common lyre of the ancient Greeks (Gr. *χέλυσ*, tortoise), which had a convex back of tortoise-shell or of wood shaped like the shell. According to tradition Hermes was attracted by sounds of music while walking on the banks of the Nile, and found that they proceeded from the shell of a tortoise across which were stretched tendons which the wind had set in vibration (*Homeric Hymn to Hermes*, 47-51). The word has been applied arbitrarily since classical times to various stringed instruments.

CHEMICAL ACTION is said to occur whenever the properties of a substance are so completely altered that we are entitled to regard the product as a new and distinct substance. In the burning of coal, for example, a combustible, black solid is chemically changed by union with the oxygen of the air, to produce ash, water vapour and gases, all of which differ from the original coal in all their important properties. The chemist pictures the properties of every substance as being determined by the chemical make-up of its molecules, *i.e.*, by the nature of the atoms which are contained in each molecule of the given substance, and the manner of their arrangement. Thus water is different from carbon disulphide because the molecules of water contain atoms which are different from those contained in molecules of carbon disulphide: on the other hand the molecules of grape sugar (glucose) and fruit sugar (fructose) contain identical atoms in identical proportions but the properties of these substances are nevertheless different because the atoms are differently arranged in the two kinds of molecules.

The complete change of properties which is associated with chemical action is therefore to be considered as being accomplished by the recombination or rearrangement of atoms to produce new sorts of molecules. The science of chemistry (*q.v.*) is mainly concerned with the study of chemical change. The details thus far accumulated are commonly presented in chemical text-books under headings that correspond with the various individual elements. The general results and such principles as are generally applicable to chemical change, form the subject-matter of physical chemistry (*see* CHEMISTRY: *Physical*), and of these the present article deals with a few which are related most intimately to the factors that determine *how quickly* a given chemical change may be accomplished.

CHEMICAL REACTION VELOCITY

The variation in the speed of chemical change and its dependence on the nature of the reacting substances is illustrated on the one hand by the almost instantaneous change (explosive reaction) which transforms a stick of dynamite into gaseous products, and on the other, by the very slow change by which a steel girder is converted into a pile of iron rust, a process which may require thousands of years. It will only be possible to explain why some changes proceed so rapidly and others with such extreme slowness when we are able to state the cause of chemical change in general. At present, we can merely conclude that this is due to the action of electrical forces, the nature of which we are beginning to understand as the result of recent observations which have provided us with information concerning the inner structure of the atoms themselves. (*See* ATOM.) It usually happens, as Julius Thomsen (1854) and Marcellin P. E. Berthelot (1867) first emphasized, that rapid and energetic chemical reactions take place with the liberation of greater quantities of heat than sluggish reactions although this rule is subject to many exceptions.

A second factor determining the speed of chemical change is the *concentration of the reactants*. By this we mean the amounts of the different reacting substances in unit volume. Thus C. F. Wenzel, in 1777, observed that metals dissolve in moderately concentrated acids more rapidly than they do in very dilute acids. Indeed it was soon recognized, as a result of the work of Claude Louis Berthollet in 1803, that whether a given chemical change or its reverse takes place sometimes depends only on the concentrations in which the several reacting substances are brought

together. In such instances the effect of concentration outweighs the effect of the nature of the reacting substances, loosely termed "chemical affinity." The earliest accurate observations of the effect of concentration on the velocity of chemical changes were made by L. Wilhelmy (1850), who showed that the rate of conversion of cane sugar into glucose and fructose in the presence of an acid is at every moment very nearly proportional to the concentration of the cane sugar. These observations constituted the first definite proof that the influence of the concentration of a reacting substance can be quantitatively stated, but did not lead to any generalized statement.

It is only in the simplest type of chemical change, in which the change may be accomplished with a single molecule of a given reactant, that the velocity of the change is proportional to the first power of the concentration of that reactant. If n molecules of a reactant are required to accomplish the chemical change the velocity of the change is proportional to the n th power of the concentration of that reactant. In many cases n will be indicated by the chemical equation for the change. Thus $2\text{H}_2 + \text{O}_2 = 2\text{H}_2\text{O}$, indicates that the formation of water from hydrogen and oxygen demands two molecules of hydrogen for every molecule of oxygen, and thus that the rate at which water is formed at any given temperature is proportional to the first power of the concentration of oxygen but to the square of the concentration of hydrogen. In more complicated reactions, however, the chemical equation gives no clue to the power to which the concentration must be raised in calculating reaction velocity, for the chemical equation often expresses only the total effect and final result of a series of simpler consecutive chemical changes, the slowest of which determines the speed at which the series of changes as a whole may be accomplished. *Changes in pressure* are without effect on the velocity of chemical change, save in so far as pressure may determine concentration, as happens especially with mixtures of gases.

A third factor which affects the velocity of chemical change is the *temperature*. With rare exceptions, which can be readily explained, an increase of temperature increases the rate at which a chemical change will take place. Milk quickly turns sour on a warm day; and a mixture of hydrogen and oxygen, prepared safely enough at room temperature, explodes when it is heated by an electric spark. Commonly an increase of 1°C increases the velocity of a chemical change 10% or more, and most reactions at the temperature of boiling water proceed with several hundred times the velocity observed at room temperature. This striking effect of temperature is examined mathematically later.

A fourth factor is the *presence or absence of particular substances which may increase or diminish the velocity of the chemical change, without being themselves permanently altered*. Thus the velocity of a reaction between substances dissolved in water is different from the velocity of the same reaction, when the solvent is alcohol or benzene. Certain chemical reactions, including many of the most important in animals and plants, appear only to take place in the presence of these substances, which apparently need only be present in relatively small quantities. Changes of this sort are grouped under the head of *catalytic action*, or *catalysis* (*q.v.*); the substances essential to bring about the chemical changes between the reactants are called *catalysts*, or, in the case of the animal and plant ferments, *enzymes* (*q.v.*). The phenomena of catalysis and adsorption (*q.v.*) are closely connected with reaction velocity.

Finally, the velocity of a chemical change may be determined by the supply of energy to the reacting system from an external source. If this is light energy we have the phenomena of *photochemistry* (*q.v.*); if electrical energy, the velocity of the reaction will depend on the principles discussed under *electrochemistry* (*q.v.*), especially the laws of Faraday. (See *ELECTROLYSIS*.) The transformations of matter which occur in radioactive changes (see *RADIOACTIVITY*) differ from ordinary chemical changes in proceeding at rates which are determined entirely by the inner structure of the atoms of the radioactive elements, and are thus quite independent of the states of combination of those elements and even of the temperature.

CHEMICAL EQUILIBRIUM

Law of Mass Action.—We have referred to the observation of Berthollet that the concentration of the reactants is often sufficient to determine whether a given reaction or its reverse will take place. In this way we may explain why it so often happens that a chemical change fails to become complete, and comes to an apparent halt before the reacting material has been completely transformed. Evidently the forward reaction, transforming reactants A and B into resultants A' and B', is accompanied by a reaction which transforms A' and B' into A and B. Thus each reaction offsets the other, and the chemical change accordingly remains incomplete. The result is chemical equilibrium, commonly formulated with reversed arrows, thus:

The proportions in which the different reactants are present in a mixture of substances which have attained a condition of chemical equilibrium are determined by a principle discovered by C. M. Guldberg and P. Waage in 1867. These investigators showed that the state of equilibrium attained in a reversible reaction can be interpreted on the assumption that the equilibrium state is the result of the equality of the speeds of the two opposed reactions, for each of which the velocity v or v' can be expressed in terms of a constant multiplied by the concentrations of the reacting substances, expressed by [A], [B], or [A'], [B']. The velocities of the two opposed reactions are therefore given by $v = k[\text{A}][\text{B}]$ and $v' = k'[\text{A}'][\text{B}']$. At equilibrium these two velocities are equal, hence

$$k/k' = [\text{A}'][\text{B}']/[\text{A}][\text{B}] = K$$

in which K is the so-called equilibrium constant. If the reaction corresponds with

the equilibrium constant may be written

$$K = \frac{[\text{A}]^{m'}[\text{B}]^{n'}}{[\text{A}]^m[\text{B}]^n}.$$

The practical importance of a knowledge of equilibrium constants, calculated as just shown, will be realized when it is remarked that *the equilibrium constant for any given reaction at a given temperature is independent of the concentrations in which the reactants are brought together*. Thus when the numerical value of the constant has once been determined we may substitute this in the preceding equations, and determine the proportions in which the reactants and resultants will be intermingled when equilibrium is reached, starting from any given initial concentrations.

Though the mathematical expressions just given (commonly called *mass-action* expressions) may be regarded as empirical statements of actual laboratory experience with systems in chemical equilibrium, nevertheless they may readily be derived from the *kinetic theory*. (See *MOLECULE*.) It may be assumed in the simplest case that the interaction of two reactants A and B is the result of collision between the respective molecules. It follows that the rate of change should be proportional to the frequency with which such collisions occur. The frequency with which a given molecule of A collides with molecules of B is proportional to the number of the latter in unit volume, *i.e.*, the molecular concentration of B; and in the same way the frequency of the collisions between a given molecule of B and the molecules of A is proportional to the molecular concentration of the latter. The total number of collisions between the molecules of A and B is therefore proportional to the product of the molar concentrations. Kinetic considerations thus led to $v = k[\text{A}][\text{B}]$ which is the expression for the reaction velocity, embodied in mass-action expressions above. The coefficient k in this formula is called the *specific reaction rate*, and represents the velocity when the concentrations of the two reacting substances are each equal to unity. It depends on the nature of the reacting substances, the temperature, and the medium (solvent) in which the reaction occurs. In the case of gaseous reactions there is no solvent to be considered, but it may be noted that many apparently gaseous reactions are in reality surface reactions, *i.e.*, reactions which take

place largely, if not entirely, on the surface of the walls of the containing vessel. (See ADSORPTION.)

Influence of Temperature on Reaction Velocity.—The principal weakness of the explanation which makes chemical change depend solely on collisions between molecules, is that the velocity should be approximately the same for all reactions of the same type under like conditions of temperature and concentration. Actually rate of chemical change is a highly specific quantity, which varies widely from one reaction to another. Moreover, if we conceive of reaction rate as depending altogether on the frequency of collisions between molecules, we find it impossible to account for the extraordinary influence of temperature on reaction rate. In the simplest cases, an increase of temperature of 10°C would speed up the molecules sufficiently to make collisions between them several per cent more frequent, whereas reaction velocity in that temperature range is actually increased several hundred per cent. The simplest way of explaining this involves the assumption that molecular collision is not always followed by chemical change. Collision between molecules, when reactants A and B are transformed into resultants A' and B', is a *necessary* but not *sufficient* condition for reaction.

We have then to account for the fact that the proportion of the colliding molecules which react grows rapidly larger as the temperature is increased. We might assume that reaction takes place only when molecules collide that happen to have velocities exceeding some stated critical velocity. Yet the proportion of such molecules, calculated from Maxwell's law of distribution of velocities (see MOLECULE), does not increase with increasing temperature in a way that fits the experimental facts. Actually, as was first pointed out by Svante Arrhenius (1889), the specific reaction rate k for many common reactions varies with the temperature in a way that may be explained by assuming that only a very small proportion of the molecules are in a condition to react on collision. In other words the vast majority of collisions do not result in chemical change but this only takes place when the energy content of the colliding molecules is much greater than the average. The proportion (α) of the effective collisions increases rapidly with the temperature and if the extra energy (energy of activation) required at the absolute temperature T is represented by q , then the empirical relation of Arrhenius for the connection between reaction velocity and temperature may be put in the form

$$d\ln\alpha/dT = q/RT^2 \quad \text{or} \quad \alpha = e^{-q/RT}.$$

At a given temperature, the value of α thus depends on the magnitude of q and diminishes as q increases. When the concept of active molecules is incorporated in the mass action equation, this becomes

$$v = k \cdot e^{-q/RT} \cdot [A] \cdot [B]$$

in which q represents the extra energy of the impact which is required for the collisions between molecules of A and B to be effective.

This discussion neglects the possibility that even molecules possessed of the requisite supply of energy may not react when they collide unless they happen to be disposed in favourable positions with respect to each other at the moment of collision. A collision between molecules of ethyl alcohol and acetic acid, for example, would not be expected to produce a molecule of ethyl acetate unless the hydroxyl and carboxyl groups are favourably placed when collision takes place. Neglecting this difficulty, the coefficient k can be evaluated in terms of specific and general constants and the equation for the bimolecular reaction becomes

$$v = N\sigma^2 \sqrt{8\pi RT(1/m_A + 1/m_B)} \cdot e^{-(q_A + q_B)/RT} \cdot [A] \cdot [B]$$

in which N is the Avogadro number (6×10^{23}), σ is the mean diameter of the molecules and m_A and m_B are the molecular weights of A and B. This equation, due to W. C. McC. Lewis (1918) does actually enable us to calculate certain reaction rates with an accuracy which is satisfactory in view of the fact that the effective diameter of the colliding molecules is known only very roughly.

Unimolecular Reactions.—The assumption embodied in the preceding discussion, that chemical change occurs when molecules collide which happen to be possessed of a more-than-average supply of energy, at once meets the difficulty that many reversible reactions are known in which collisions between molecules appear to play no part. Thus when phosphorus pentachloride dissociates, forming phosphorus trichloride and chlorine, according to the equation $\text{PCl}_5 \rightleftharpoons \text{PCl}_3 + \text{Cl}_2$, each molecule of PCl_5 would seem to decompose independently of other molecules in accordance with the ordinary law of chance. By some chemists it has been asserted that such chemical changes (called *unimolecular reactions*) are not really possible. The fact that they seem to be of frequent occurrence is presumed to be explained by the presence of traces of foreign substances, which, in acting as catalysts, provide the means for interpreting the mechanism on the basis of molecular collisions.

Recent work would, however, seem to have definitely established the occurrence of non-catalysed gaseous reactions which proceed in accordance with the requirements of the unimolecular type of change over a wide range of concentration. An explanation of these has been sought in the radiation hypothesis, according to which the cause of the reaction is to be found in the selective absorption of radiant energy. The mechanism of the photochemical change would on this view be extended to all types of chemical reaction (see PHOTOCHEMISTRY). The wave-length of the active radiation can be derived from the heat of activation of the molecules by Planck's relation, $q = h\nu$ (see QUANTUM THEORY), but in general the reacting substances afford no evidence of the requisite absorption bands. For this and other reasons the radiation hypothesis cannot be said to be acceptable. For a fuller discussion see *Trans. Faraday Soc.* (1922).

On the other hand, it seems probable that the apparently unimolecular reactions are primarily due to molecular collisions, for it is only necessary to assume that the molecules activated by collision are for the most part deactivated by further collisions before they have time to reach that particular internal phase which is essential for chemical change to occur and the observed facts can be readily accounted for.

Since the molecules of the reaction products are the result of collisions between active molecules of the reactants and therefore, in general, distinguished by a high energy content, it follows that such "hot" molecules may hand on their excess of energy to other molecules of the reactants leading to a so-called chain reaction. Such chain reactions constitute a type which is illustrated by the combination of hydrogen and chlorine.

Chemical Activity.—Reference may now be made to the results which have followed from the application of thermodynamics to the problems of chemical action. Although the time factor is alien to the processes with which thermodynamics is concerned, the arguments peculiar to this branch of analysis can of course be applied to the states of equilibrium which are finally attained in reversible reactions. If the reacting substances are ideal gases (or solutes) thermodynamic reasoning leads to results which are identical with the expression for the law of mass action which follows from the kinetic theory. When the substances are not ideal, thermodynamics leads to the conclusion that the concentration terms in the mass-law expression should be replaced by the corresponding *activities*. The activity or *effective concentration* a of any substance is defined by the relation $\Delta F = RT \log a/a_0$, in which ΔF is the diminution of free energy associated with the reversible transformation of the substance from the condition defined by a to a standard condition defined by a_0 . The activity in the standard condition may conveniently be taken as unity.

In practical applications the attempt is made to calculate activity or effective concentration by multiplying the actual concentration c , for the given substance, by an activity coefficient, f , which is itself a function of the concentration. Then by substituting $a = fc$ for c , in the mass-action expressions given above, more nearly constant values for the equilibrium constant are found than would otherwise be obtained. To be fully satisfactory, this method would require that the activity coefficient, f , by

means of which actual concentrations are converted into effective concentrations, should be independent of the nature of the reaction in which the given substance takes part. This has been found not to be the case. Accordingly J. N. Brönsted has introduced the assumption that the interaction of two substances A and B involves the intermediate formation of a "collision complex" X and this leads to $v = k c_A \cdot c_B \cdot f_A \cdot f_B / f_X$ where f_X is the activity coefficient of the complex. In this connection it may be noted that the activity coefficients of ions depend largely on their charges and on the ionic strength of their environment. (Ionic strength is calculated by taking half the sum of products formed by multiplying the concentration of each cation or anion in the solution by the square of its valence.) In accordance with the theory of P. Debye and E. Hückel, the relation may be expressed in the form $-\log f = 0.5x^2/\mu$ where x is the valence of the ion concerned and μ is the ionic strength of the solution in which it is present. This relation, when combined with Brönsted's reaction-velocity formula, affords results for ionic reactions of varied types which are in accord with experimental observations provided that the solutions are sufficiently dilute.

IONIC THEORY

Relative Strengths of Acids and Bases.—Although much recent work has been concerned with the precise significance of "active mass," the classical interpretation of this as synonymous with molecular concentration has yielded results of the greatest importance in the interpretation of the manifold phenomena associated with aqueous solutions of acids, bases and salts (*see SOLUTION*). Such substances are, in general, electrolytic conductors, and in accordance with the theory of Arrhenius are ionized to a greater or less extent. The traditional view, that salt formation corresponds with the neutralization of opposite qualities which characterize the acids and bases respectively, finds simple expression in the ionic theory, for, according to this, acids are substances which increase the hydrogen-ion concentration of water, whilst bases have the opposite effect. In aqueous solutions, the concentration of the hydrogen ion is directly connected with the hydroxyl-ion concentration, by the mass-action expression

$$K = \frac{[H^+] \cdot [OH^-]}{[H_2O]}.$$

In all dilute aqueous solutions however the concentration of the un-ionized water $[H_2O]$ is nearly constant (55.5 moles per litre). Accordingly in all dilute aqueous solutions, whether *acid, alkaline or neutral*, the product of the two ion concentrations has a nearly constant value (10^{-14} at 25°C). In neutral solutions hydrogen-ion (sometimes called hydron) and hydroxyl-ion are present in equal concentrations (10^{-7} gram-ions per litre at 25°C). In acid solutions the concentration of hydrogen-ion exceeds that of hydroxyl-ion; in alkaline solutions the reverse is true. Yet hydroxyl-ion is never completely absent from acid solutions, nor hydrogen-ion from alkaline solutions, for the concentrations of the two ions must always be so related that the ion-product, $[H^+] \cdot [OH^-]$ has the constant value 10^{-14} , at 25°C . At higher temperatures the ion-product increases very rapidly, attaining a value of about 60×10^{-14} at 100°C .

Equivalent solutions of different acids show very great differences in the hydron concentration. These are exhibited very clearly when the electrical conductivities of such solutions are compared or when a comparison is made of the velocities with which certain reactions take place when these are subjected to the catalysing influence of the various acids. The two series of numbers show a close parallelism which finds a simple interpretation in terms of the view that the differences between the acids are primarily due to differences in their respective degrees of ionization. The conductivity is indeed proportional to the concentration of the ionized fraction of the acid and the catalytic effect is determined for the most part by the hydron concentration. The application of the mass law to the equilibrium between the un-ionized acid and the corresponding ions, as represented by

$$K = \frac{[H^+][A^-]}{[HA]} = (c\alpha)^2/c(1-\alpha) = c\alpha^2/(1-\alpha)$$

for the ionization constant, c being the molar concentration of the acid and α the fractional degree of ionization. In spite of the charges on the ions, this relation between the concentration of the acid and its degree of ionization is in very close agreement with the actual behaviour of weak or slightly ionized acids, as was clearly demonstrated by Wilhelm Ostwald. The results obtained in this connection constitute in fact the strongest and most comprehensive evidence as yet available in favour of the quantitative application of the law of mass action to states of equilibrium. The Ostwald dilution law does not hold for solutions of salts or more active (largely ionized) acids or bases. Many chemists have indeed arrived at the conclusion that most salts are completely ionized, at all concentrations. (*See also ELECTROLYSIS; and HYDROGEN IONS, DETERMINATION OF.*)

Neutralization of Acids by Bases.—In the neutralization of an acid by the gradual addition of a base, the essential reaction consists in the combination of hydrogen ions with hydroxyl ions until the concentration of both reaches the value for pure water, viz., 10^{-7} gram-equivalents per litre (25°), which condition is shown by suitable indicators (*q.v.*). The constancy of the heat of neutralization of the strong acids by the strong bases is explained in this way (*see THERMOCHEMISTRY*). If one equivalent of a base BOH is added to a solution which contains one equivalent of each of two different acids HA_1 and HA_2 , the relative proportions of the two acids which are neutralized afford a measure of the so-called relative affinities of the acids for the base. Because of such differences stronger acids tend to displace weaker acids from the corresponding salts. Such displacement effects, however, are not always the result of a difference in the affinities of the acids, for complications may occur in consequence of the removal of one of the resultant substances from the sphere of action in the form of an insoluble solid or a volatile gas; e.g., the displacement of nitric acid by the relatively very weak acid hydrogen sulphide in accordance with $2AgNO_3 + H_2S \rightarrow Ag_2S + 2HNO_3$ is directly due to the insolubility of silver sulphide. The basic affinities of a pair of acids can in fact only be derived from a determination of the relative amounts which are neutralized by a base when the system is homogeneous. If x is the fraction of the acid HA , which is neutralized by the base, BOH, in the above solution, the resulting equilibrium can be represented by

and the evaluation of x , which can be effected by a variety of physical methods, gives us the ratio $x/(1-x)$ which expresses the affinity of HA_1 relatively to HA_2 . When such affinity values, referred to an acid chosen as standard, are compared, it is found that the acids form a series which is essentially the same as the series given by the relative conductivities and catalytic activities. It can be shown that this experimental result is generally consistent with the hydron theory of acids for the application of the mass law to the equilibria which are involved in the above mentioned competition of two acids for a base shows that the affinity ratio $x/(1-x)$ is the ratio of the degrees of ionization of the two acids. The fact that $x/(1-x)$ is independent of the nature of the base is also explained at the same time. Similar considerations apply to the relative strengths of bases. At a given concentration their characteristic properties can be explained in terms of the hydroxyl-ion concentration. Since degrees of ionization vary with the concentration, it is convenient to eliminate the latter. This can be done by comparing the strengths of acids and bases in terms of the respective ionization constants.

CHEMICAL APPARATUS. Underlying all types of chemical work is analysis. Much of the industrial work has to do with

FIGS. 1-21.—GENERAL CHEMICAL APPARATUS (THE NUMBERS REFER TO DESCRIPTIONS IN THE TEXT)

determining purity, evaluating raw materials, and certifying manufactured products.

Many means are employed. The chemist may work under high pressures or in almost complete vacua, at temperatures approaching absolute zero and those of melting tungsten. It is obvious then, that the apparatus employed by the chemist will vary with the work in hand. He needs porcelain, which will stand sudden and extreme changes of temperature; glass that is insoluble in the majority of the reagents he uses, which will stand great temperatures, and possesses high mechanical strength; and fashioned crucibles, dishes and other devices from platinum, fused quartz, and special alloys. The balances he employs are of the highest precision. He utilizes the wave length of light in measurement. The spectrograph, the microscope, the polariscope are familiar instruments. Burettes enable him to measure by the drop, while sensitive electric instruments have become essential in determining the concentration of hydrogen ions, the modern

method of determining acidity. He uses the burning flame to judge contents by colour or to identify the lines in the spectro-scope; electric conductivity becomes the measure of pureness of the water employed in analysis; and the complexity of the compounds and mixtures with which the chemist has to deal, frequently introduces in the perfection of apparatus problems well nigh as difficult as the one with which he began. (H. E. H.)

The forces which operate in chemical change are effective only through extremely short ranges as measured on the everyday scale of length. Accordingly one of the first tasks of the practical chemist is to subdivide his reagents (*see REAGENT*) so finely that they can be brought into very intimate contact. This intimate mixing is most effectually promoted by dissolving these reagents in suitable media. Hence a considerable proportion of laboratory apparatus is devoted to the processes of solution, extraction, filtration, precipitation, evaporation, distillation and desiccation. All of these have to do with the treatment of chemicals either in or separating

from the dissolved condition. For these purposes reagent bottles, filter pumps, water baths, funnels, evaporating basins, filter stands, flasks and stills are employed. Representative types of such apparatus are here illustrated.

Certain important chemical reagents are gaseous under the ordinary laboratory conditions. Special apparatus has been devised to deal with such highly volatile fluids. Gases are conveniently manipulated in drying towers, aspirators, Kipp's gas generators, wash-bottles and glass tubing connections including three-way taps.

Chemical analysis (*see* CHEMISTRY: *Analytical*) is the touchstone by which all chemical theories must ultimately be tested. Hypotheses which fail to pass through this ordeal are regarded as no longer valid or useful. A considerable proportion of laboratory equipment subserves the essential needs of the analyst. The accurate chemical balance is described elsewhere (*see* BALANCE), but among the typical requirements of analytical chemistry figured below are the following: weighing bottles, crucibles, potash bulbs, measuring vessels (burettes, pipettes, graduated flasks and cylinders), and special apparatus, for example, for the quantitative evaluation of arsenic and carbon dioxide and for the determination of vapour density.

The following list refers to the accompanying illustrations of apparatus commonly used in a chemical laboratory:

General Apparatus.

1. Spatulas, for dealing with small quantities of material without touching by hand. They may be of metal (*a* and *b*) or vulcanite, etc. (*as c*).
2. Three-way taps: (*a*) A half turn connects the upper limb with the right-hand tube. (*b*) T-piece and tap (*see* section).
3. (*a*) Spring clip (Mohr's pattern). (*b*) Screw clip.
4. Reagent bottle.
5. Filter pump, for use with filter flask and either Buchner funnel (fig. 7) or Gooch crucible (fig. 31). The stream of water is broken up at the jet A, and the resulting drops tend to carry air down the tube B. This is capable of reducing the pressure as low as the vapour pressure of water.
6. Water-bath and rings on tripod. The bath is nearly filled with water which is heated by a burner underneath. Removal of one or more of the rings enables any circular vessel (*e.g.*, an evaporating basin) to rest in the hole of appropriate size, and its contents are slowly heated or evaporated. A constant-level device may be fitted (*see* fig. 13) to maintain the level of the water in the bath and obviate refilling.
7. Büchner funnel fitted in filter flask, which is attached to a suction pump (*see* fig. 5). A circle of filter paper is placed on the perforated bottom, and the material retained by it can be sucked dry, washed, and pressed.
8. Test-tube stand and test tubes.
9. Evaporating basin (porcelain).
10. Filter stand, funnel, and beaker. A filter paper is folded so as to fit in the funnel as shown; it retains solids, while liquids filter into the beaker.
11. Bunsen burner, whereby gas is burned with any desired amount of air, giving at will a luminous or a non-luminous flame (*see* FLAME).
12. Retort stand with rings, clamps, and bosses.
13. Still (with constant-level device) and condenser.
14. Drying tower. Similar in function to 16, but used where gases have to be passed through solids.
15. Aspirator. If this is filled with water, and the stopper is replaced by a cork carrying a tube, on opening the tap water will flow out, and this will draw air through the tube, which may be attached to any other apparatus.
16. Wash-bottle for gases (Drechsel pattern). If the gas is bubbled through the liquid it can be freed from one or more impurities, *e.g.*, it can be dried by passage through concentrated sulphuric acid, or freed from carbon dioxide by a solution of caustic potash.
17. Kipp's apparatus. Hydrochloric acid (HCl) is allowed to run down the central tube and rise so as to act on the iron sulphide; if the tap is open, sulphuretted hydrogen (H₂S) is expelled by the "head" of acid; when the tap is shut, the gas forces the acid into the top bulb and no more gas is produced. If marble is used instead of iron sulphide, carbon dioxide (CO₂) is obtained.
18. Desiccator. Strong sulphuric acid or granular calcium chloride is kept in the bottom; the material to be dried is spread on a watch-glass or clock-glass resting on the gauze. If the nozzle is attached to a pump, the vacuum produced accelerates drying.

General Apparatus—continued.

19. Separating funnels: (*a*) pear-shaped—also called a dropping funnel; and (*b*) cylindrical. If ether has been used to extract an organic substance from water, two layers are formed and the lower (aqueous) layer can be run off. Similarly, if chloroform had been used instead of ether, the lower layer would be the chloroform extract.
20. Pestle and mortar (of porcelain).
21. Foot blow-pipe.

FIGS. 22-37.—CHEMICAL APPARATUS USED FOR ANALYSIS

Apparatus used in Analysis.

22. Crucible and lid; used for igniting precipitates.
23. U-tube. May be filled with granulated soda-lime to absorb carbon dioxide, or with pumice soaked in sulphuric acid to absorb water vapour. The ground-in taps can be turned to shut off connection with the outer air.
24. Potash bulbs. A 50% aqueous solution of potash is in the bulbs. A gas has to bubble through the three in succession and is dried in the calcium chloride tube; the increase in weight, if any, is due to carbon dioxide absorbed from the gas.
25. Weighing bottles, for protecting material from the air while it is being weighed. A portion of the contained substance is tipped out and the whole reweighed, the amount of material thus taken being the difference in weight.

26. Wash bottle. A fine stream of water (or other liquid) can be directed where required.
27. Dropping-bottles: (a) By slightly pressing the rubber teat and releasing the pressure, a few drops are drawn up in the teat and can be squeezed out one at a time when the nozzle is withdrawn. (b) Liquid flows along the capillary tube at A when the bottle is tilted, and a drop falls from B, air entering through another channel at C. Used chiefly for indicators (q.v.).

28. Measuring cylinder. Used for rough measurements of volumes of liquids.

29. Burette in stand. Used for titrations. The graduated scale shows what volume of liquid is delivered (see CHEMISTRY: Analytical).

30. Drying oven. The hole at the top carries a cork through which a thermometer is inserted. Material to be dried is placed (in a suitable container) on the tray. The holes in the tray allow the stems of funnels (holding filter paper) to be inserted. A burner is placed under the oven. Similar ovens may be heated electrically. A steam oven is similar but is surrounded by a "jacket" in which steam circulates.

31. Gooch crucible with rubber cone, glass adapter and filter flask. The bottom of the crucible is perforated with small holes, and a mat of asbestos is formed on it by pouring in a pulp of asbestos and water, sucking it nearly dry and completely drying it in the oven. Used for filtering, washing, drying and weighing precipitates.

32. Carbon dioxide apparatus (Schrötter). The apparatus is weighed with all constituents separated; the hydrochloric acid (HCl) is then allowed gradually to flow on to the solid; the carbon dioxide (CO₂) given off carries some aqueous vapour which is retained by the concentrated sulphuric acid (H₂SO₄), and after warming, cooling and passing air through to displace all the carbon dioxide, the apparatus is reweighed, the loss of weight being due to the carbon dioxide given off.

33. Apparatus for detection and estimation of traces of arsenic (Thorpe). The suspected material is treated so that its arsenic is obtained in acid solution, which is electrolysed and thereby reduced to arsine, AsH₃; this is dried by calcium chloride and purified by lead acetate in tube A, and decomposed by heat from a micro-burner B; it then deposits arsenic as a "mirror" at C, the density and colour (yellow, brown or black) depending upon the amount of arsenic.

34. Standard flask. Contains the stipulated volume when filled to the mark with a liquid at 15° C. Used for preparing "standard" solutions, i.e., those containing a definite quantity of solid dissolved in, e.g., 1,000 cu.cm. of solution.

35. Mouth blowpipe; used for directing a small flame jet on to the substance being analysed (usually supported on a block of charcoal).

36. Crucible tongs; may be tipped with platinum for refined work. These should be placed with points upwards, so as to avoid contamination such as would occur if the points were downwards touching a working-bench.

37. Pipettes (not to scale). (a) If filled exactly to the mark by suction, will then deliver the stipulated volume on draining for 15 seconds after continuous flow has ceased. (b) Can be used for gradual addition of small quantities which are read off on the scale.

Special Apparatus.

38. Victor Meyer apparatus. A liquid such as aniline is kept boiling in the outer bulb. The side arm holds a small stoppered tube containing a weighed quantity of a liquid. When the apparatus ceases to emit bubbles of air, the small tube is tipped into the inner bulb (a little sand or mercury being present to break the fall and save fracture), and the vapour of the liquid displaces its own volume of air, which ascends the eudiometer, displacing water or mercury, and is there measured. Vapour densities are thus determined (see ASSOCIATION; and STORCHOMETRY).

39. Soxhlet extractor. The material to be extracted (crushed seeds

or cocoa) is placed in a "thimble" of filter paper. Ether is boiled in the flask, passes by the side tube A to the reflux condenser C, the liquid drops into the thimble where it accumulates till it reaches the level of the top of the side arm B, and then siphons over to the flask. Several extractions remove all the fat, which can then be weighed in the flask if all the ether is evaporated from the flask through a non-return condenser.

40. Beckmann thermometer (top only). For showing small temperature changes (of 5° or less) with an accuracy of 0.001° C. By taking mercury from, or returning it to, the reservoir, the range can be altered at will. (A. D. M.)

FIGS. 38-40.—SPECIAL CHEMICAL APPARATUS (THE NUMBERS REFER TO DESCRIPTIONS IN THE TEXT)

CHEMICAL ARTICLES. The main article CHEMISTRY includes a general survey of the *History of Chemistry*, and also deals comprehensively with the various branches of this science; viz., *Inorganic, Organic, Physical and Analytical Chemistry*. These and their practical applications are treated in fuller detail in the chemistry articles appearing in this encyclopædia.

There are articles elucidating fundamental ideas and definitions, and explaining chemical changes; e.g., ACID; ATOMIC WEIGHTS; CHEMICAL ACTION; COMBUSTION; ELEMENTS, CHEMICAL; MOLECULE, CHEMICAL; OXIDATION AND REDUCTION. ATOMIC WEIGHTS contains a list of the elements; these are described individually, with their chief compounds, in separate articles. There are also separate articles on the more important compounds; e.g., AMMONIA. The compounds of carbon, apart from the simple ones treated under the separate headings (such as CARBONATES; CARBONYLS; METALLIC; etc.), are dealt with in the organic chemistry articles.

Organic Chemistry, a main sub-section of CHEMISTRY, includes a historical introduction followed by a general survey of the subject under the sub-heads *Aliphatic, Homocyclic and Heterocyclic Divisions*. CHEMISTRY also includes an account of *Ultimate Organic Analysis*. There are, besides, articles explaining the structure and synthesis of carbon compounds; e.g., ISOMERISM and STEREOCHEMISTRY; and processes and reagents are described under HYDROGENATION, GRIGNARD REAGENTS, etc. The various types and classes of compounds are dealt with in AZO COMPOUNDS, ALKALOIDS, ALCOHOLS, ESTERS, KETONES, CAMPHORS, PURINES, etc.; separate articles are devoted to the more important sub-groups and members of these classes; e.g., BUTYL ALCOHOLS, ALCOHOL (ethyl alcohol), BENZENE, CHLOROFORM, PYRIDINE, etc., many being of industrial and medical importance. The chief substances present in living matter are treated under ALBUMIN, CARBOHYDRATES, CHLOROPHYLL, PROTEINS, RESINS (NATURAL AND SYNTHETIC), etc.; and several organic acids have separate headings; e.g., ACETIC, CARBOLIC, OXALIC and URIC ACIDS. Dyes and pigments are dealt with in DYES, NATURAL AND SYNTHETIC, and under various headings such as ALIZARIN, ANTHOCYANINS AND ANTHOXANTHINS, GLUCOSIDES (NATURAL), INDIGO, OCHRES, etc.

The physical chemistry articles include ADSORPTION, ASSOCIATION, CATALYSIS, HYDROGEN ION CONCENTRATION, PHOTOCHEMISTRY, VALENCY, THERMOCHEMISTRY, etc. The industrial processes are treated in CHEMICAL ENGINEERING, COAL TAR, DISTILLATION, EXPLOSIVES, SUGAR, etc., and under the separate headings of the various important elements and compounds. There is a large collection of diagrams of apparatus used in a chemical laboratory under CHEMICAL APPARATUS, and the methods of chemical analysis are described in CHEMISTRY: Analytical, which includes *Inorganic* (qualitative and quantitative), *Ultimate Organic* and *Gas Analysis*, and in BLOWPIPE and INDICATORS. There are also short articles interpreting old-fashioned names and dealing with various theories of the alchemists, e.g., ALCHEMY; AQUA REGIA, BRIMSTONE, ELIXIR, HARTSHORN, SPIRITS OF; and VITRIOL.

CHEMICAL ENGINEERING. The branch of engineering which relates to the "design, construction, erection and operation of industrial plants in which matter undergoes a change of state or composition." This definition, due to the Institution of Chemical Engineers, is rather broad but logical. A chemical engineer should possess a good general knowledge of chemistry and physics, a special knowledge of physical chemistry and thermodynamics, a thorough grasp of mechanical and electrical engineering and of those branches of civil engineering which deal with the strength of materials and the theory of design of struc-

tures. There is little doubt that the material rewards of scientific chemical engineering are greater to-day than in any other branch of engineering, while its national importance cannot be over-estimated.

Since the ultimate object of the chemical engineer is economic production, industrial economics and law, business management and factory organization must be given a primary place in his training. He must be able to devise simple and effective methods of recording operations and determining actual costs, prepare designs, specifications and estimates free from ambiguity and error, report efficiently on any problem investigated, obtain technical information readily and compile and index it for future use.

Practical Basis.—The practice of chemical engineering has naturally preceded the scientific analysis of its principles. Typical chemical engineering operations have been performed in certain industries to such an extent as to evolve special types of plant peculiar to those industries. The chemical engineer, however, must understand the underlying scientific principles upon which such operations or processes depend, so as to be able to design an efficient plant for any particular purpose, rather than allow it to be evolved by rule-of-thumb guesswork with expensive large scale experiments and costly alterations in construction before reasonable efficiency is obtained.

Scientific Basis.—The adoption in the factory of one unit of weight and volume together with the decimal system is a first step and facilitates recording, avoids errors, saves time and makes the scientific control of processes comparatively easy.

Chemical Engineering Operations.—Chemical engineering operations are of three general types: (a) the conveyance and storage of materials; (b) the production, transfer and conservation of heat, and (c) the treatment of materials. In these processes an exact knowledge is required to secure the greatest industrial efficiency, and questions relating to rent, capital cost, repairs, labour and superintendence, output, material efficiency, character of the market, etc., must be considered. Unfortunately some of these conditions vary from year to year and the chemical engineer must be somewhat of a seer to achieve the greatest success.

Transport.—Transport is often the most important item of the cost of production; in the factory itself, the cost of carrying materials to a machine is often as great as that of the operation conducted. Methods of weighing and measuring materials in their progress through the factory need careful study, for it is only by maintaining the highest rate of output as a uniform thing, that the best results can be obtained.

Flow of Fluids.—In industrial practice fluids may flow in two distinct ways, usually referred to as "stream-line" and "turbulent" flow. The former method offers advantages in certain operations, filtration, classification, separation, etc., while the latter is essential to secure the greatest heat transfer. The criterion by which it can be approximately determined whether stream-line or turbulent flow is occurring in a tube is given by the value of the

modulus $\frac{vd\rho}{\mu}$ where v is the velocity of the fluid, d the diameter of the tube, ρ the density of the fluid and μ its viscosity. The value of the fraction is the same in any system of units and when it exceeds 2,000 the flow is turbulent. The transport of fluids in factories is obviously a simple and cheap process, so that a solid material which is used in solution will be transported more cheaply and conveniently by dissolving it at once and pumping the solution to stock tanks, rather than by conveying the solid itself.

Semi-fluids.—The laws governing the flow of semi-fluids such as dry sand, wheat, etc., which occupy an intermediate position between solids and liquids, must be understood. A peculiarity of such materials is that their flow from an orifice is proportional to the cube of the area of the orifice and independent of the head.

Transfer of Heat.—The production and transfer of heat involve a knowledge of combustion, the study of fuels, their calorific value and intensity, while the electrical generation of heat is becoming more and more important in the development of industrial processes. The design of furnaces of different types, often a

matter of rule-of-thumb evolution, involves questions of heat transmission and radiation, the factors of which are very difficult to estimate. The great diminution in density of the hot gases as the increasing importance of radiation as a factor in heat transmission, as the temperature rises, are points needing the most careful study. The loss of heat from exposed hot surfaces by radiation and air contact may be fairly closely estimated, a factor often very important in the operation of a plant. The transmission of heat through a metal diaphragm from gas to gas, gas to liquid, saturated vapour to liquid, liquid to liquid, gas to solid etc., varies so enormously as to demand the most careful experimental research. The transmission of heat from a gas to a gas through copper 1 mm. thick, is of the order of 5 calories per sq. m. of surface per hr. per one degree C. of temperature difference between the gases; under similar circumstances the transmission from gas to non-boiling water is about 20 calories, from liquid to liquid about 350 calories, and from steam to water about 1,500 calories. If the liquid is boiling the heat transfer may be increased greatly; it is usually at least twice and may be over four times that of non-boiling liquid. The importance in steam boiler and evaporators of keeping the liquid constantly boiling is obvious. Again, an increase of velocity of either fluid will raise the rate of heat transmission considerably by an amount which is capable of estimation. The effects of corrosion, of deposited scale, the influence of salts in solution and of precipitates in suspension on the rate of heat transmission are matters of great industrial importance. When a gas or liquid moves over a solid surface or when a gas moves over a liquid surface there exists a film of the moving fluid over the stationary substance in which there is practically no motion. The thickness of this film is mainly responsible for the great differences in heat transmission already mentioned. Much chemical engineering research is necessary to elucidate these questions adequately, and great wisdom in design is necessary to secure the highest economic efficiency.

Solid Materials.—In the treatment of solid materials, size reduction by crushing, grinding and impact must be well understood. The relative cost of the different methods and machines and the different character of the final products must be known, for the size and uniformity of the solid material treated in a chemical operation has, in practically every case, a profound influence on the cost of production of the final product. The separation of solid particles from each other and from liquids involved in the processes of sifting—electrical, magnetic, hydraulic and air separation, classification, flotation, filtration, centrifuging, etc.—often determines the profitable treatment of the material. New discoveries in flotation and similar methods of separation have in recent years proved of the highest value.

Power.—A study of the power required for different processes is of importance and many prevent false conclusions. In size reduction for example, the power required is approximately proportional to the increased surface produced, so that a simple calculation will readily show how costly it is to produce the finest powders from solid materials. Many processes, though well understood, are difficult and costly; their avoidance or replacement by some other method at another stage of the process are important points in the economic possibilities of manufacture. Again, it is a common experience in technical manufacture, that a method by which one process is rendered easy may cause a later process to fail and give rise to a faulty product.

Processes of Separation and Extraction.—Processes of separation in which a change of physical state takes place are peculiar subjects of study to the chemical engineer. Leaching and extracting, evaporation, distillation and condensation, drying, crystallization, absorption and adsorption, etc., are processes requiring the highest research. Processes of extraction which formerly took 12 hours are now being carried out more efficiently in one hour as a result of chemical engineering study. Evaporation is now being done in many works at one-sixth of its former cost, while distillation and condensation in certain industries are now carried on with a fuel saving of nearly 80% in comparison with earlier methods.

Wet Distillation.—The process of "wet" distillation, i.e., distillation by means of direct steam, is used in many industries for

separating a particular substance, essential oil, hydrocarbon, etc. If such substance does not mix with water, then each develops that particular vapour pressure which it would have if heated separately to the same temperature, and the sum of the vapour pressures is the pressure in the still. A study of the vapour pressure curves of each substance and the conditions of decomposition of the particular one, will give the most profitable still pressure at which to work. By this alone, materials which at ordinary pressure require 200 parts of steam to distil one part of substance, may be treated under suitable pressure by 30 parts of steam. Again, by a reduction of pressure before condensation has taken place, a separation of the particular substance will take place and the steam may be economically "boosted" back into the still.

Drying Processes.—The drying of gases, liquids and solids is a common requirement of many industries. The study of drying and drying plant may mean a change from comparative failure to great success. The drying of gases by chemical reagents such as calcium chloride, which after absorbing moisture is itself dried by hot air or flue gases, cooled and again used, is well understood, but the use of absorption processes for this purpose is a development in industry of the last few years. The "gels" (silica gel, alumina gel, etc.) are treated in a similar way to the calcium chloride previously mentioned, but are free from any risk of failure through overheating, and have many other advantages.

Gas Masks.—The efficiency of the gas mask in warfare is paralleled by the importance of the same means in peace to recover benzene and other solvents from air and gas effluents, to remove sulphur from oil and to perform many other chemical functions in a physical way. The absorption of water by "silica gel" is so energetic, and the substance can be so readily regenerated that its general use for refrigeration may be only a matter of time. The chemical engineering problems involved in this process are both interesting and profitable. The treatment of the air of factories to render it constant in temperature and humidity also offers a large field to the chemical engineer. (See ADSORPTION.)

Chemical Processes.—The treatment of materials in chemical reactions such as roasting, calcining, destructive distillation, electrolysis, catalysis, hydrolysis, fermentation, etc., demands careful consideration of physical, chemical and engineering factors of increasing exactitude. An examination of these processes on a laboratory scale must precede their study on a manufacturing scale. The chemist does the former and the chemical engineer the latter. Additional factors involving time of reaction, strength of materials, presence of traces of impurity, cost of materials and plant, continuous or discontinuous operation, the handling and disposal of by-products, etc., arise. Increase in efficiency can be obtained by changing from intermittent to continuous working.

Materials.—The design of plant involves the preparation of flow sheets showing the flow and expenditure of material, energy, time and labour, the experimental study of the nature and properties of the materials involved in plant construction and a continuous search for new materials to meet the conditions of service better than those at present in use. The name of a material, unfortunately, is no indication that it is suitable for a chemical engineering purpose. "Chemical cast iron" is a distinct kind of cast iron, characterised by the amount of silicon, sulphur and carbon content and its treatment. Other materials, alloys, bricks, compositions, cements, etc., must be specified for their work both as to composition and history if success is to be made certain. In recent years, great advances have been made in the production of chemical engineering materials of construction, silica-ware, stoneware, glass, alloy steels, alloys, etc., all of which tend to cause modification of design. The effect of heat on the strength of materials is becoming better known every year and the production of non-scaling steels which are as strong at a white heat as ordinary mild steel at the ordinary temperature will make many developments possible which have hitherto failed.

Lay-out of Plant.—The lay-out and construction of factories involves a knowledge of several branches of civil engineering and cannot be neglected, for the erection of buildings, heavy plant and chimneys on marshy soil is a common necessity in industry. The construction of foundations, roadways, railways, etc., must also

be understood. In the provision of power, heat and light, the relative value and use of the different methods must be considered for a sound view to be taken as to whether steam, electricity, gas or water-power shall be used. High-pressure steam providing power by means of turbines which exhaust into receiver from which evaporating steam may be drawn, presents the most efficient power plant in many chemical industries, while electricity generally provides the best method of power distribution, and occasionally of heating, in process work. The use of producer water gas for heating and other purposes must not be neglected nor the value of compressed air and hydraulic water for many purposes. Finally the chemical engineer must be familiar with the Factory Acts, trade union law and all those legal questions which factory managers have to face. (J. W. H.)

CHEMICAL WARFARE. The use of irritant and poisonous substances to diminish the resistance of an opponent is probably as old as organized warfare. Thucydides describes two instances of the use of burning sulphur and pitch in sieges in the

Peloponnesian War, and throughout classical times and the middle ages such methods were frequently employed, Greek fire being a device of this kind. As war became more mobile and the range of actions increased, the opportunities for using such a weapon in its primitive form disappeared, but in 1855 Lord Dundonald proposed a scheme for burning sulphur on a large scale under favourable wind conditions in order to reduce the Malakoff work during the siege of Sebastopol. The suggestion was rejected on the ground of inhumanity.

International Law.—The use of toxic substances was foreseen at The Hague Peace Conference of 1899, when the governments represented pledged themselves not to use any projectiles the sole object of which was the diffusion of asphyxiating or harmful gases. At The Hague Convention of 1907 the following rule was adopted: "It is expressly forbidden (a) to employ poison or poisoned arms, (b) to employ arms, etc., of a nature to cause unnecessary suffering." It has been argued that toxic gases were not contemplated as coming within the scope of this clause; but this was not the interpretation put on it by most of the Powers, and the Treaty of Versailles assumed that their use in any form was contrary to international law. This view was confirmed by the nations represented at the Washington Conference in 1922.

Gas in the World War.—At the outbreak of war none of the combatant nations had made any preparation for the use of gas or were equipped with any defence against it; but, after the failure of the initial German attack and the development of trench warfare, means were sought by the Germans to assist the artillery preparation for an offensive against entrenched positions, in order to get back to a state of open warfare again. Proposals to use gas were made at an early date and on Oct. 27, 1914, shrapnel containing an irritant substance (dianisidine chlor-sulphonate) were used by the Germans at Neuve Chapelle without, however, any success. They were followed by shell containing a strong lachrymator (xylyl bromide) in place of part of the charge of high explosive, which were used on the Russian front in Jan. 1915, when the low temperature made the lachrymator ineffective.

The introduction of gas as an effective weapon in modern warfare really dates from April 22, 1915, when the Germans discharged chlorine from cylinders on a front of about 4 m. at Langemarck opposite a sector held by the French. The effect of the discharge, which came as a complete surprise, against unprotected troops was to eliminate for a depth of several miles all resistance on the front affected. A similar attack was made on the Canadian front near Langemarck on April 24. Owing to various reasons the Germans failed to take advantage of the opportunity offered by these first attacks for a decisive stroke, and within a few days the Allied troops were equipped with a crude form of respirator and the immediate danger was over. The Germans soon found considerable difficulties in combining an infantry attack with a cylinder discharge which was dependent on a favourable wind. Consequently they abandoned the cloud gas attack except as a means of inflicting casualties on the Allies. From Dec. 1915 their cloud attacks became more dangerous owing to the admixture of an increasing amount of phosgene with the chlorine, which added greatly to its toxicity, but of course the protection of the Allies was improving at the same time.

The Allies were quick to adopt retaliatory measures: the first British gas attack was made at Loos on Sept. 25, 1915, with cylinders of chlorine, and from then to the end of the war frequent cloud discharges were made, as the wind was more often favourable to the Allies than to the Germans.

As a weapon for use in an attack the gas shell offers great advantages over the cloud discharge, as it allows the use of a much greater variety of toxic substances and its employment is independent of the wind. The Germans scored one success with lachrymatory shell in the Argonne in July 1915, but the French were the first to realize the possibilities of a gas shell filled with a highly toxic gas such as phosgene, with a small bursting charge just sufficient to open the shell. The French shell of this type surprised the Germans in the spring of 1916 and was of considerable assistance in the defence of Verdun. Subsequently the Germans modi-

fied their gas shell to the same type and made considerable use of them both at Verdun and in the Somme battle.

Gas in 1917.—In this year gas shell first became a serious factor in the tactical situation, as both the Allies and the Germans had provided themselves with considerable quantities as a result of their experience in 1916. The German shell contained mainly trichlormethyl chloroformate and chlorpicrin, toxic substances of a semi-persistent nature; the French phosgene, or prussic acid; the British chlorpicrin or lachrymators. Gas shells were used mainly during active operations for neutralizing the enemy's batteries, for interfering with the movements of troops, and for general harassing purposes. By firing gas shells it was always possible to compel the wearing of a respirator and, especially at night, this resulted in a considerable diminution of efficiency. Also sudden bursts of lethal shell were fired at targets known to be occupied in order to produce casualties by surprise before respirators had been adjusted. In order to achieve this it was necessary to set up suddenly a high local concentration of gas, and the most effective weapon for this purpose was the Livens Projector, first used at Arras in March 1917. This was a crude form of trench mortar, firing a bomb weighing 60 lb. and containing 30 lb. of phosgene. Large numbers could be installed together and fired simultaneously at the same target, producing very high concentrations of gas without any warning beyond the flash and noise of the discharge and the bursting of the bombs. The projector became one of the deadliest weapons of those used in trench warfare.

July 1917 is notable for the introduction of two new gases by the Germans, who had seen that, with the improved methods of protection, gases such as those mentioned above, which all betray their presence at once by their immediate irritant action on the eyes and respiratory tract, were losing much of their value. They therefore introduced two new substances, dichlorethyl sulphide, commonly known as "mustard gas," from its smell, or as "Yperite," from the place where it was first used and diphenylchlorarsine. Mustard gas was the most effective agent used in chemical warfare and it was responsible for the majority of gas casualties. Owing to its slight smell it is less easily detected than other gases; and, although it produces no immediate sensations of discomfort, exposure to a very low concentration is sufficient to put a man out of action, owing to the effects of the gas on the eyes and lungs. As the liquid has a low vapour pressure at atmospheric temperature and reacts very slowly with water, it may remain for days or weeks in the soil and continue to produce a dangerous concentration of gas wherever the temperature is high enough. In addition to its effects on the eyes and lungs, serious blisters are produced either by splashes of the liquid or by contact with ground or any object contaminated by it.

Diphenylchlorarsine, a solid melting at 46° C, when finely divided in the air causes sneezing, irritation and intense pain in the nose and throat, and nausea. There is a slight delay in the onset of the symptoms. Bottles of this substance are embedded in high explosive shell, so that on the burst of the shell it is scattered as a fine dust in the air. Unless respirators are provided with a special form of filter they may be penetrated by these small particles, and the resulting sneezing may compel the removal of the respirator. However, this did not occur in the field of battle.

Gas in 1918.—For their offensive in 1918 the Germans made great use of gas shell, on which they relied to produce rapid neutralization of the Allied artillery, thus enabling them to reduce the length of their preliminary bombardment to a few hours without previous registration. As much as 80% of gas shell was allotted for some tasks. The gas shell available at this date can be divided into two classes, from the point of view of tactical employment in an attack:—

(1) Shell containing liquids such as mustard gas, which may persist for long periods in the soil and cannot be used on ground which it is intended to attack or occupy.

(2) Shell containing volatile liquids such as phosgene or diphosgene, or non-volatile solids such as diphenylchlorarsine, which owing to their low persistence may be used immediately before an attack.

The Germans used shell of the first class on the flanks of the

attack and in other sections of the front to produce casualties, while the preliminary bombardment before each attack was mainly with gas shell of the second class, which compelled the continuous wearing of the respirator and added greatly to the strain and fatigue of the troops and interfered with movement and communication. The weather conditions in each offensive were suitable for gas shell except on July 15, when the attack failed. The Allies also were using large quantities of gas shell in 1918, including mustard gas after June, and so effective had they proved for various tasks that the proportion of gas shell was steadily increasing. It is noteworthy that no gas was used in naval actions during the World War, or from aircraft.

Gas As a Weapon.—The use of gas has added many complications to war. It compels all troops to carry a respirator, involving additional weight of equipment and training. The presence of gas compels the wearing of the respirator, thereby reducing a soldier's efficiency by the interference with vision, speech, etc., and by the added fatigue, and the respirator cannot be worn for long periods without arrangements which admit of eating and drinking. Also the possibility of a gas attack increases the strain on troops both by the constant watchfulness that is necessary and the moral effect of gas, which cannot be neglected.

Gas accounted for a moderate proportion of the casualties in the War. During the last year of the war 16% of the British and 33% of the American casualties were due to gas, but its tactical value cannot be judged by casualties alone; it proved invaluable in the neutralization of artillery, interference with movement, and hampering communication. Also, by the use of a persistent gas like mustard gas, it was possible to make a position

Types of Gas Used.—The gases used in war can be classified roughly as follows, according to the predominant effect which they produce on the body, although many gases may belong to more than one class:—

(1) Acute lung irritants, *e.g.*, chlorine and phosgene, which exert an intense irritant action on the respiratory organs leading to acute pulmonary oedema.

(2) Lachrymators (tear-gas), *e.g.*, xylol bromide, which even in low concentrations make vision impossible by their irritant action on the eyes, although the effect may not continue.

(3) Paralysants, *e.g.*, prussic acid, which in sufficiently high concentration cause death almost instantaneously by their effect on the nervous system.

(4) Sensory irritants of the eyes, nose and upper respiratory passages (also called sternutators as they often cause sneezing), *e.g.*, diphenylchlorarsine; these are often effective in very low concentrations, causing intense pain in the eyes, nose and throat, nausea, and subsequent depression.

(5) Vesicants, *e.g.*, mustard gas, which cause inflammation and blistering of the skin, eyes and respiratory tract, the effect being produced as a rule some hours after exposure.

Broadly speaking, the gases in groups (1) and (3) may be regarded as lethal agents, those in groups (2) and (4) as putting a man out of action immediately, though temporarily, while the vesicants are delayed in action but have a great casualty producing power, even when used against troops trained in defensive measures.

The following tables give the principal gases used in the World War, with a brief summary of their important characteristics:—

| Acute Lung Irritants | | | | | | |
|--|--|----------------------|-----------------------------------|--|---|---|
| Substance | Chemical formula | Date of introduction | Boiling point, degrees centigrade | Approximate concentration to incapacitate a man in a few seconds owing to lachrymation or coughing | Approximate concentration which if breathed for more than one or two minutes would cause actual damage to the lungs | Used by B = British F = French G = Germans |
| Chlorine | Cl ₂ | 1915 | −33·6 | 1: 10,000 | > 1:10,000 | B F G |
| Phosgene | COCl ₂ | 1915 | +8 | 1:100,000 | 1:50,000 | B F G |
| Trichloromethylchloroformate | Cl·COO·CCl ₃ | 1916 | +128 | 1:200,000 | 1:50,000 | F G |
| Chloropicrin | CCl ₃ NO ₂ | 1916 | +112 | 1:200,000 | 1:50,000 (Cumulative) | B F G |
| Lachrymators | | | | | | |
| Xylol bromide | CH ₃ C ₆ H ₄ CH ₂ Br | 1915 | +218 | 1:2,000,000 | .. | G |
| Ethyl iodoacetate | CH ₃ ICOOC ₂ H ₅ | 1916 | +180 | 1:5,000,000 | 1:50,000 | B |
| Paralysants | | | | | | |
| Hydrocyanic acid | HCN | 1916 | +26·5 | > 1:2,000 (immediately fatal) | No cumulative action | B F |
| Sensory Irritants of Eyes, Nose and Chest (Sternutators) | | | | | | |
| Diphenylchlorarsine | (C ₆ H ₅) ₂ AsCl | 1917 | +333 (M.P. +43) | < 1:10,000,000 | 1:50,000 | G |
| Diphenylcyanarsine | (C ₆ H ₅) ₂ AsCN | 1918 | > +300 (M.P. +31) | < 1:10,000,000 | 1:50,000 | G |
| Ethyl dichlorarsine | C ₂ H ₅ AsCl ₂ | 1918 | +156 | 1:500,000 | 1:20,000 | G |
| Vesicants | | | | | | |
| Dichlorethyl sulphide (Mustard gas) | (CH ₂ ClCH ₂) ₂ S | 1917 | +217 (M.P. +14) | .. | 1:100,000 with 60 min. exposure | B F G |

untenable except at the cost of heavy casualties; this occurred at Bourlon Wood in Nov. 1917 and at Armentières in April 1918. In such ways gas proved itself a valuable auxiliary to existing weapons. Again, a heavy gas would penetrate into the deepest dugout which was immune against high explosive or shrapnel, and gas shell might be effective without getting a direct hit, as the gas from each burst to the windward of a target would drift over it. And, above all, gas always carries with it the possibility of surprise, the importance of which is considerable in any kind of warfare.

Methods of Liberating Gases.—The method selected for liberating gas depends partly on the object to be attained and partly on the physical properties of the gas.

Gas can be discharged:—

(1) from cylinders as cloud gas;

(2) from projectiles, *e.g.*, shell, trench mortar bombs, or projectors, either as a true gas or in the form of liquid drops or as a fine dust;

(3) from aeroplane bombs as from other projectiles;

(4) as a spray from containers carried in aeroplanes or tanks.

Cylinder or cloud gas attacks were made by installing a large number of steel cylinders containing compressed gas in the front line trenches and discharging these in a suitable wind so that the gas was carried over into the enemy's trenches. The gas used must be denser than the air so that it does not rise when discharged, and it must be at a sufficient pressure to ensure that the contents of the cylinders are discharged rapidly when the valves are released. Chlorine and mixtures of chlorine and phosgene were employed mainly for this purpose. Gas projectiles contain a toxic substance and a bursting charge, and the effect on burst depends on the nature of the filling and the size of the burster.

A volatile substance like phosgene forms a small cloud which drifts with the wind, while with a liquid like mustard gas part of the filling is dispersed as a cloud, but a considerable proportion will be scattered over the ground in or near the shell crater and may continue to give off a dangerous concentration of vapour for days. A solid such as diphenylchlorarsine is dispersed as a cloud of fine dust which drifts down wind leaving no persistent effect. Similar results are obtained with aeroplane bombs. Liquids can be sprayed either from tanks or aeroplanes, but in the latter case there may be considerable losses by evaporation if the drops have to fall from a great height.

Protection Against Gas.—Like all other weapons gas has its antidote. This takes the form of a respirator which filters out toxic materials from the air before it reaches the lungs. The early patterns consisted of a pad of cotton waste, dipped in a solution of sodium thiosulphate and sodium carbonate, which was tied over the mouth. This was replaced by flannel or flannelette helmets, dipped in various solutions, which were worn over the head and protected the eyes as well as the lungs. The measure of protection obtainable by such means is obviously very limited, and the use of a general absorbent such as charcoal has many advantages to offer. All the combatants in the World War finally adopted respirators in which the inspired air was filtered by passing through activated charcoal in a small container, with various admixtures of other substances to increase the protection against specific gases. Pads of cellulose or other filtering material were added to give protection against the fine particles produced by the explosion of shell containing such substances as diphenylchlorarsine. The container was attached directly to an impermeable facepiece held in position by elastic bands over the head so as to make an airtight joint round the face, as in the German respirator, or it was carried in a haversack and connected to the facepiece by a rubber tube carrying a mouthpiece, as in the British Box Respirator, in which case it was necessary to prevent breathing through the nose by a nose-clip attached to the facepiece. In the French respirator, which resembled the German, the inspired air passed over the glass eyepieces and prevented the depositions of moisture on them, thus securing clear vision.

The ideal respirator represents a compromise between safety and military efficiency. Its weight must be small, it must admit of easy carriage and rapid adjustment, and offer little resistance to breathing; also it must be comfortable to wear and interfere as little as possible with vision and hearing. At the same time it must give a sufficient measure of protection against all gases likely to be encountered in the field.

But the respirator alone is no guarantee of safety; the soldier must be able to recognize the presence of gas by its smell or other effects, and thus know when he needs protection. Also he must be trained to carry out his duties while wearing a respirator for long periods so as to suffer the minimum loss of efficiency.

Apart from these measures of individual protection, there are a number of precautions which may be grouped together under the heading of collective protection. These include arrangements for giving the alarm in case of a gas attack, the provision of protected shelters in which men can remain during a gas attack without wearing respirators, or to which they can go to eat or drink, and the clearing of gas and the decontamination of ground after a gas attack of any kind.

Future of Chemical Warfare.—After the experience of the war there is a general feeling that gas may figure again in some future war in spite of international agreements, and all nations

are taking steps to equip their troops with protection against it. Gas proved itself so effective a weapon, it offers such possibilities of surprise, and it can be produced so easily in the peace equipment of the chemical industry that it would be rash to discount the possibility of its use under the conditions of war psychology. Moreover it is difficult to maintain that it is less humane than other weapons. For example, the total recorded British gas casualties were 180,983 with 6,062 deaths, whilst the mortality amongst other battle casualties was about 25%, and it was striking how small a proportion of the gas casualties who survived suffered any permanent disablement.

Most forecasts of future wars assign to gas an important rôle in its use from aircraft against mobilization and manufacturing centres and even against the civilian population, and under certain conditions there can be little doubt as to its effectiveness. As regards its use in the field, much depends on whether the type of warfare is such as to permit of its employment in sufficient quantity and concentration. Position warfare offers exceptional opportunities for its use, but the tank and the aeroplane, which favour a return to some form of mobile warfare, may themselves become the means by which gas may be discharged most advantageously.

AMERICAN DEVELOPMENTS

Chemical warfare deals with the direct application of chemicals as weapons. It is concerned with the chemical not as an explosive agent to propel a bullet or fragment of metal, but as the active agent itself to cause casualties by irritation, burning or asphyxiation; to make ground untenable; to screen operations or lessen the enemy's fire power by creating a smoke screen; and to damage enemy material or personnel in incendiary effect or otherwise. The adoption of chemicals as weapons was as logical as it was inevitable in the World War in which all the principal combatants were nations highly developed scientifically. When the German advance was halted by the Battle of the Marne, both sides firmly entrenched themselves. A stalemate resulted; it was found that neither side could advance. The machine gun had increased fire power to such an extent that only by an impossible superiority in man power could ground be captured. Mobility for either the Allies or the Germans had gone. Through the winter of 1914 and 1915, with both sides out of artillery ammunition, the man in the trench was bound to have a technical superiority over the attacker.

Both sides felt the need of a weapon that would search out the defender in his rabbit warren of trenches and holes and rob him of the protection of his sandbags and earthworks. The scientist provided this weapon in chemicals, a weapon continuous in time and space. Thus modern chemical warfare was born. The first definite gas attack against American troops took place on the night of Feb. 25, 1918 near Seicheprey. Approximately 175 projectiles containing phosgene and chloro-picrin were fired. The troops on this sector were warned that just such an attack might be expected. In spite of this warning, heavy casualties occurred. From that time on, American troops were subjected to numerous gas attacks, the results of which are best shown by the final report of the surgeon general, U.S. Army, on casualties. The question of whether or not chemical warfare is humane is very definitely answered by this report, which shows that while 27% of all American casualties were caused by gas, only 2% of these casualties resulted in death. Of the other 73% of battle casualties, more than 24% resulted in death. Furthermore, the report of the surgeon general shows conclusively that gas does not increase susceptibility to tuberculosis in after years and that there is seldom any permanent after effect from gassing. It is the opinion of military men who know the facts that gas is not as inhuman

a method as the more familiar methods of warfare and causes less suffering than the bullet, bayonet, high explosive or shrapnel shells.

That gas played an important part in the war is shown by the fact that it accounted for some 800,000 casualties divided approximately as follows: Russia, 275,000; France, 190,000; England, 181,000; Germany, 78,763; United States, 70,552; Italy, 13,300. Protection against gas started immediately after the first gas attack and has kept pace with the offensive since that time. The first protective devices were pads of cotton dipped in a chemical solution and tied over the mouth and nose. Then followed helmets saturated with a neutralizing solution worn over the head, thus protecting the eyes as well as the lungs of the wearer. Increase in the use of chemicals during the war caused the development of the type of mask or respirator which consists in an impermeable facepiece to which is attached a filter containing absorbent charcoal and neutralizing chemicals.

The American army adopted as their first mask one modelled after the British box respirator. This consisted of a facepiece to protect the eyes and respiratory tracts, a canister which filtered the air breathed and a canvas satchel for carrying. The facepiece of rubberized fabric covered the whole face and was equipped with a rubber mouthpiece and nose clip. A hose tube joined the canister to the facepiece. The air breathed passed through the canister where it was purified, up the tube and through the mouthpiece to the lungs of the wearer. Breathing through the nose was prevented by the nose clip. The American gas service recognized the discomfort of the mouthpiece and nose clip, and before the end of the war had developed a respirator which combined the advantages of the French Tissot mask which had no mouthpiece or nose clip, and the British box respirator. The present gas mask of the United States army is a further development of the American Tissot mask. The air is filtered by a highly activated form of coconut shell charcoal and neutralized by granules of soda lime and permanganate in the canister. It passes through a corrugated hose tube into the facepiece and across the eyepieces, thus keeping these clear. The facepiece is made of moulded rubber covered with stockinet for protection and is modelled accurately to fit all types of faces. The whole apparatus is carried in a satchel under the soldier's left arm. Protection of the body against burns from mustard gas is obtained by treating clothing with certain chemicals.

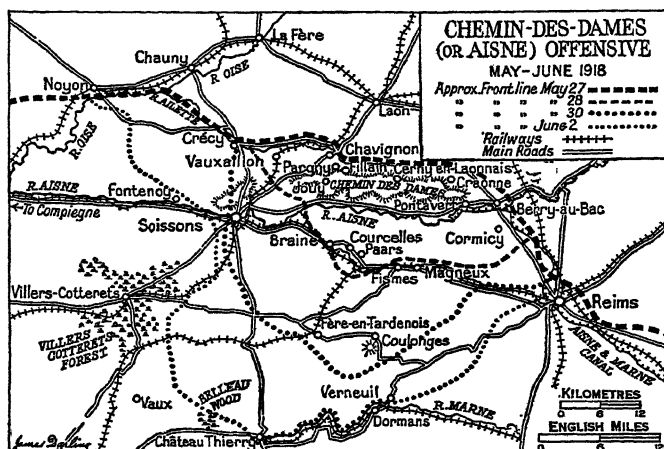

Chemical warfare presented to the Allies not only a new tactical and strategic problem but an industrial problem as well. The quantities of chemicals necessary to carry out gas operations on a large scale are measured in hundreds of tons. In the manufacture of practically all chemical agents, the Germans had the initiative. The sacrifices in men and money which the Allies had to make before their chemical plants could compete with German production served as a terrible lesson and in the future a State will regard its chemical industry as one of its greatest assets for national defence.

There has been considerable discussion as to the international legal status of chemical warfare. Several treaties have been proposed to outlaw the use of chemicals in war. In 1922 the United States ratified the Five-Power Treaty at Washington. It sought to make illegal the use in war of poison gas and submarines. This treaty required ratification by all five powers, before it became binding on any one of the contracting parties. As all have not ratified the treaty, it is not in effect. An authoritative letter published in the *Congressional Record* of Dec. 13, 1926, brings out clearly the point that no proposed treaty, if such treaty should finally become effective, would prevent the United States from doing all work in chemical warfare that it felt necessary to insure itself against surprise or disaster in a war. Most military writers agree that chemical warfare is an effective and humane weapon and that its use on a large scale must be viewed as probable. Although stabilized warfare brought about and presents the greatest opportunities for the use of gas, the development of chemical warfare in connection with the aeroplane and the tank must be counted upon to make even more advantageous its employment in mobile warfare.

CHEMIN-DES-DAMES, BATTLE OF THE, 1918.

This is the name commonly given to the May offensive of the Germans in 1918, the third act of their plan to reach a military decision before the weight of American numbers could turn the scales against them. It is alternatively called the Battle of the Aisne, 1918, or, less frequently, the Battle of Soissons-Reims. After the relative failure of the German offensives of March and

The German attack, launched May 27 on a 30 mile front, took the Allies by surprise and drove them across the Aisne to the Marne. Here, German efforts to push westwards failed.

April it was essential for the Germans, if they wished to preserve the initiative, to deliver another powerful blow without delay. The choice of the front of attack and the battle-ground fell on the oft-contested chain of heights between the Ailette and the Aisne, the Chemin-des-Dames.

Dispositions for the German Attack—The German Supreme Command had decided to attack with the VII. and I. Armies against the sector between north of Soissons and Reims. If this attack proceeded favourably it was to be prolonged on the right over the Ailette to the Oise and on the left as far as Reims. The German Supreme Command hoped that the push southward would succeed in reaching the neighbourhood of Soissons and Fismes, and by this means attract strong forces from Flanders, so that it might be possible to continue the attack there according to plan. Preparations began about the middle of May. The VII. Army under Böhm was charged with the main attack across the Chemin-des-Dames, the I. Army under Below with the neighbouring attack on the left in the direction of Compiègne. The right wing of the main attack, the LIV. Corps and the VIII. Res. Corps, had the task of pushing forward in a south-westerly direction on both sides of Soissons. The XXV. Res. Corps was to strike on both sides of Cerny-en-Laonnais direct towards Braine, and on the east to take as much country as possible towards the south; the IV. Res. Corps was to attack the high ground at the eastern end of the Chemin-des-Dames, immediately north of Craonne; in concert with this on the left the LXV. Corps was to occupy with its left wing the river bend north of Berry-au-Bac. Of the I. Army only one corps was to be launched at the outset to throw the opposing forces over the Aisne-Marne canal. The corps was to provide itself with bridgeheads in order to take the heights of Cormicy if the attack of the VII. Army proceeded favourably.

For success there were two essentials; the first, surprise; and the second, effective artillery preparation. Most elaborate and thorough precautions were taken to secure secrecy. As regards artillery preparation the ascent of the steep slopes on the heights of the Chemin-des-Dames was only possible if the Germans should succeed in silencing the bulk of the opposing guns. All registration was to be abandoned in order to surprise the enemy as much as possible. The first aim was to be a thorough gassing of the Allied position right down into the Aisne valley. Preparations were completed by the evening of May 26, 1918. At that moment four battle-worn British divisions were resting in this

supposedly quiet sector. They had been sent to the French front, after strenuous exertions in the battles of the Lys, in return for French reinforcements which had gone north to the aid of the British in the later stages of that "backs to the wall" struggle. On the tranquil Aisne they could recuperate, while still serving a useful purpose as guardians of the trench-line. It was too quiet to be true. But the uneasiness of the local British commanders—shared by certain of their French neighbours—was slightly discounted by their Allied superiors. On May 25 they received from French headquarters the message that "in our opinion there are no indications that the enemy has made preparations which would enable him to attack to-morrow."

At one A.M. on May 27, 1918, a terrific storm of fire burst on the Franco-British front between Reims and north of Soissons, along the famous Chemin-des-Dames; at 4:30 A.M. an overwhelming torrent of Germans swept over the front trenches; by mid-day it was pouring over the many unblown bridges of the Aisne, and by May 30 it had reached the Marne—site and symbol of the great ebb of 1914. Happily, it proved to be "thus far, and no farther." Like the two great preceding offensives of March 21 and April 9, that of May 27 achieved astonishing captures of ground and prisoners, but it brought the Germans little nearer to their strategic object. And, even more than its predecessors, its very success paved the way for their downfall. To the reasons for this we shall come. But why, a month after the last onslaught, in the north, had come to an end, why, when there had been this long interval for preparation and for examination of the situation by a now unified command, should a surprise greater than any before have been possible?

It has long been known, of course, that the French command, that directly concerned with the safety of this Aisne sector, did not believe in the likelihood of an attack. Nor did the British higher command, which, however, was personally concerned with the front in the north. But the intelligence of another of the Allies, better placed to take a wide survey, did give the warning—only to be disregarded until too late. On May 13, a fortnight after the fighting in Flanders had died away, the British intelligence came to the conclusion that "an attack on a broad front between Arras and Albert is intended." Next day this was discussed at a conference of the intelligence section of the American Expeditionary Force, and the head of the battle order (of the enemy) section gave a contrary opinion holding that the next attack would be against the Chemin-des-Dames sector, and between May 25 and 30.

The warning in detail was conveyed to the French general headquarters, but fell on deaf ears. Why should credence be given to an opinion coming from such a new army, not yet tested in battle, over the verdict of war-tried and highly-developed intelligence services? The warning was reiterated, however, and the French intelligence was won over to its acceptance. But now, as at Verdun two years before, the operations branch opposed until too late the view of its own intelligence. This time, however, it was less blameworthy, for it was tugged the other way by the comforting assurances of the commander of the VI. French Army, in charge of the Chemin-des-Dames sector. This general, indeed, had a still heavier responsibility, for he insisted on the adoption of the long-exploded and wasteful system of massing the infantry of the defence in the forward positions. Besides giving the enemy guns a crowded and helpless target, this method ensured that, once the German guns had eaten up this luckless cannon-fodder, the German infantry would find practically no local reserves to oppose their progress through the rear zones. In similar manner all the headquarters, communication centres, ammunition depots and railheads were pushed close up, ready to be dislocated promptly by the enemy bombardment.

Pétain's instructions on a deep and elastic system of defence had evidently made no impression on this Army command, so that it was still less a matter for wonder that the protests of junior British commanders met with a rebuff. It was unfortunate, also if perhaps less avoidable, that when the four British divisions forming the IX. Corps (Hamilton Gordon) arrived from the north at the end of April, their depleted ranks filled up with raw drafts

from home, they were hurried straight into the line, as the best place to complete their training. The backbone of the Aisne defences was formed by the historic Chemin-des-Dames ridge north of the river. The eastern half of this "hog's back" was to be held by the British, with the 50th Division (Jackson) on the left, next the 8th Division (Heneker), and, beyond the end of the ridge, in the low ground from Berry-au-Bac along the Aisne and Marne canal, the 21st Division (Campbell), joining up with the French troops covering Reims. The infantry of the 25th Division (Bainbridge) was in reserve.

Altogether the French VI. Army front was held by four French and three British divisions, with three and one respectively in reserve. Against these tired or raw troops, in the main attack from Berry-au-Bac westwards, fifteen German divisions, all but one brought up fresh, were to fall upon five, with two more for the subsidiary attack between Berry-au-Bac and Reims, while seven German divisions lay close up in support. Even so, the German superiority was not so pronounced as in the March and April offensives, whereas both the rapidity and the extent of their progress were greater. Yet this time the tactical surprise of the assault was unaided by the heavy ground mists which had previously helped so much by wrapping their initial advance in a cloak of invisibility. The conclusion is, therefore, that the advantage was due in part to the strategic surprise—the greater unexpectedness of the time and place—and in part to the folly of exposing the defenders so completely to the demoralizing and paralyzing effect of the German bombardment—by 3,719 guns on a front of under 40 miles. This last, indeed, was a form of surprise, for the object of all surprise is the dislocation of the enemy's morale and mind, and the effect is the same whether the enemy be caught napping by deception or allows himself to be trapped with his eyes open.

We pass to the events of May 27. For three and a half hours the unfortunate troops had to endure a bombardment of exceptional intensity. And the ordeal of those hours of helpless endurance, amid the ever swelling litter of shattered dead and untended wounded, was made more trying by crouching, semi-suffocated in gas-masks. Then the grey waves advanced—relief, if only of action, at last. Three-quarters of an hour later they had reached the crest of the ridge in the centre near Ailles. This uncovered the flank of the left British division, the 50th, forcing its survivors to fall back down the other slope. Next to it, the 8th Division was being forced to give way, although two of its brigades held on stubbornly for a time on the north bank of the Aisne. On the British right, the attack on the 21st Division developed later; this division was awkwardly placed with the swampy Aisne and Marne canal running through the centre of its battle zone, but most of it was successfully extricated and withdrawn west of the canal. By midday the situation was that the Germans had reached and crossed the Aisne at most points from Berry-au-Bac to Vailly—helped by the fact that the order to blow up the bridges had been given belatedly. Hitherto the German progress had been evenly distributed, but in the afternoon a heavy sagging occurred in the centre, at the junction of the French and British wings, and the Germans pushed through as far as Fismes on the Vesle. This was natural, both because the joint is always the weakest point, and because the heaviest weight—more than 4 to 1—of the assault had fallen on the two French divisions in the centre and the left of the 50th Division adjoining them.

This sagging, together with the renewed German pressure, compelled a drawing back of the flanks. On the east, or British flank, this operation was distinguished by a remarkable manoeuvre of the 21st Division, wheeling back during the night through hilly, wooded country, while pivoting on and keeping touch with the Algerian division, which formed the right of the Army. After a pause in the morning of May 28, the Germans forced the passage of the Vesle, and on the 29th they made a vast bound, reaching Fère-en-Tardenois in the centre, and capturing Soissons on the west, both important nodal points, which yielded them quantities of material. The German troops had even outstripped in their swift onrush the objectives assigned to them, and this, despite the counter-attacks which Pétain was now shrewdly directing against

their sensitive right flank. On the 30th the German flood swept on the Marne, but it was now flowing in a narrowing central channel, for this day little ground was yielded by the Allied right flank, where the 19th Division as well as French divisions had come to reinforce the remnant of the original four British divisions, which next day were relieved.

From May 31 onwards the Germans, checked on the side of Reims and in front by the Marne, turned their efforts to a westward expansion of the great bulge—down the corridor between the Ourcq and the Marne towards Paris. Hitherto the French reserves had been thrown into the battle as they arrived, in an attempt to stem the flood, which usually resulted in their being caught up and carried back by it. On June 1, however, Pétain issued orders for the further reserves coming up to form, instead, a ring in rear, digging themselves in and thus having ready before the German flood reached them a vast semi-circular dam which would stop and confine its now slackening flow. When it beat against this in the first days of June its momentum was too diminished to make much impression, whereas the appearance and fierce counter-attack of the 2nd American Division at the vital joint of Château-Thierry was not only a material cement, but an inestimable moral tonic to their weary allies. In those few days of "flooding" the Germans had taken some 65,000 prisoners, but whereas this human loss was soon to be more than made up by American reinforcements, strategically the Germans' success had merely placed themselves in a huge sack which was to prove their undoing less than two months later (*see* MARNE, SECOND BATTLE OF THE). As in each of the two previous offensives, the tactical success of the Germans on May 27 proved a strategical reverse, because the extent to which they surprised their enemy surprised and so dislocated the balance of their own command.

As the disclosures of Gen. Kuhl have revealed, the offensive of May 27 was intended merely as a diversion, to attract the Allied reserves thither preparatory to a final and decisive blow at the British front covering Hazebrouck. But its astonishing opening success tempted the German command to carry it too far and too long, the attraction of success drawing thither their own reserves as well as the enemy's. Nevertheless it is a just speculation as to what might have resulted if the attack had begun on April 17, as ordered, instead of being delayed until May 27, before the preparations were complete. The Germans would have worn out fewer of their reserves in ineffectual prolongations of the Somme and Lys offensives, while the Allies would have still been waiting for the stiffening, moral and physical, of America's man-power. Time and surprise are the two supreme factors in war. The Germans lost the first and forfeited the second by allowing their surprise to surprise themselves.

(B. H. L. H.)

CHEMIST, one who, for pleasure or profit, concerns himself with the acquisition of information relating to the composition of bodies and the changes of composition which they undergo. The chemist traces his evolution from the Greek philosophers, who speculated without experiment as to the constitution of matter, through the mediaeval alchemists, who experimented with little logic, in the hope of transmuting one element into another. During the middle ages another sect, the iatro-chemists, also existed, who carried out experiments which were to make chemistry more useful to medicine. Many types of chemists exist, classed usually according to the kind of matter or the kind of change with which they are most concerned. When the individual applies his information to the production, manufacture or commercial use of commodities, he is customarily considered a chemical engineer.

CHEMISTRY. The science that is concerned with the composition of bodies and with the changes of composition they undergo. Analytical chemistry deals with the methods of separation of purer substances from mixtures, of elements from compounds, and with their estimation; synthetic chemistry treats of the methods by which complex bodies may be built up from simpler substances. In each case it is the changes of composition that concern the chemist.

The combination of atoms, and the arrangement of atoms in a molecule, used to be regarded as the special province of the chemist; while the physicist dealt with changes of state and with

the motions of the molecules: but today this distinction cannot be maintained.

With the rapid growth of modern chemistry it has become the practice to divide the theoretical study of the science into three main branches, and this conventional division is adopted in the present article, which, in addition, contains sections dealing with the history of chemistry and the practice of chemical analysis:—History of Chemistry; Inorganic Chemistry; Organic Chemistry (Aliphatic Division, Heterocyclic Division, Homocyclic Division); Physical Chemistry; Analytical Chemistry (Inorganic Analysis, Ultimate Organic Analysis, Gas Analysis).

HISTORY OF CHEMISTRY

Chemistry as a science had its origin in Egypt (*see* ALCHEMY)—the product on the one hand of much practical experience of workers in metals, glass and pottery, of users of dyeing and tanning materials; and on the other of Greek and Eastern speculation on the nature of the material world. The great school founded at Alexandria was the natural meeting place of the two streams, and from their union came in time the alchemy of the Arab conquerors, the iatrochemistry (*q.v.*) of the medical chemists and finally our modern science. In all the older cosmogonies we find the idea that there was some primordial element or principle from which the visible universe was derived. Perhaps the oldest speculations assigned to water this elementary character; its teeming life, its vivifying power, its solid deposits all marked it as the origin of things. The doctrine that water was the prime element—associated with the name of Thales—exerted an immense influence on scientific thought throughout the centuries. Van Helmont in the early 17th century thought he had proved it experimentally; it remained for Lavoisier in the late eighteenth to disprove it by more decisive experiment. But water was not the only "element" that was regarded as primordial by Greek philosophers. That air could be condensed into clouds and clouds into rain was taught by Anaximenes; water could be evaporated into air, leaving solid earth behind. Everything therefore sprang from air. That fire was the first principle of things would appeal to those who came in contact with the fire-worship of the Chaldeans, or with the religion of the Persians and Parsees, whom Zoroaster taught to look on fire as the symbol of goodness in creation. Heraclitus among the Greeks espoused the cause of fire, Pherecides that of earth; it was indeed easy to show that from combustible solids fire, air and water could be derived. That all four were primal elements, and that the varieties of matter were made from intermixture of these, was the conception of Empedocles, who regarded each element as distinct and unchangeable. But the doctrine of the Four Elements which gave so powerful an impulse and direction to chemistry was that taught by Aristotle. The importance of his doctrine lay not so much in the nature he assigned to matter, or to the modes in which qualities might be affixed to it, but in the broad principle that one kind of matter could be changed into another kind—in a word, that transmutation was possible. Underlying all tangible bodies was an indeterminate *matter-stuff* (*ύλη*) on which properties might be impressed giving matter its particular *form* (*εἶδος*).

If such fundamental qualities as hotness and dryness (or their opposite qualities, coldness and wetness) are impressed on the matter-stuff, we may conceive two qualities combining to give a primal form of matter. For instance, the combination of dryness with heat gives fire, with cold gives earth: the combination of wetness with heat gives air, with cold gives water. Moreover these qualities are not unalterable. If the coldness of water is overcome by heat, the water changes to steam or air; if its wetness is overcome by dryness it leaves earth.

Aristotle's conception differed therefore not only from the unchangeable elements of Empedocles, but from the mechanical hypothesis of Democritus, who imagined the world built up by the fortuitous meeting of rapidly moving atoms—themselves of unalterable nature.

In Egypt the Aristotelian doctrine of the four elements readily took root. Working in metals had been practised for centuries not only along the Valley of the Nile, but in the Valleys of the

Euphrates and the Indus, between which there had long existed intercourse.

How far the teaching of the Alexandrine school directly affected chemical practice among the Egyptians is doubtful. It is clear from the chemical writings that have been preserved—especially from the famous papyrus at Leyden—that the priests were well acquainted with methods for imitating gold and silver, and for covering metal vessels superficially with gold alloys so that the base metal could be removed and leave a pure gold surface which would "pass the test."

ALCHEMISTS AND IATROCHEMISTS

When the Arabs conquered Egypt in the 7th century and overran Syria and Persia, they brought a new spirit of enquiry to bear on the old civilizations they subdued. The great name that stands out in the alchemic period is that of Jabir—probably the same Geber of the Latin books *Summa Perfectionis* and *Liber Fornacum* of which the existing mss. date from the 13th century. Jabir ibn Hayyan accepted the Aristotelian doctrine of the four elements, but to these he added the special chemical elements mercury and sulphur, by which he meant not so much the two elements as met with in nature, but rather the principles giving metals their unalterable property, and the earthly impurity that it was possible to cleanse them from. Gold, unaltered by fire, contained a very pure mercury; lead and copper contained much sulphur. That gold could be extracted from copper pyrites, and that silver remained when galena was long roasted, were regarded as evidence that the lustrous crystals of pyrites and galena, looked on as metals, had been transmuted by purification from the sulphur or dross into the nobler metals.

The two alchemic elements were thus introduced; the third element "salt"—representing the residue that remained fixed after calcination—was added by the iatrochemists. These three elements constituted the *tria prima* of Paracelsus and his disciples of the 16th century. Jabir himself seems to have believed in the philosopher's stone, and the term *Kimya* may have signified the secret powder which had to be projected on the molten metal to cause transmutation.

A century after Jabir came Rhazes, physician and chemist; and he was followed by Ibn Sina, better known as Avicenna, who knew that metals could be changed in colour, but not really altered in substance.

In the 11th century Mansur distinguished between *natron* (sodium carbonate) and *qali* (potassium carbonate). He describes the preparation of a plaster of Paris, for use in surgery, by heating gypsum and mixing it with white of egg.

When the Arabs penetrated into Spain they brought with them their chemical knowledge and their love of learning. Through the Arab universities founded in Spain, the knowledge not only of alchemy, but also of much of Greek thought first illuminated the backward States of Europe. We cannot be sure of the origin of many of the Latin texts of the 12th and following centuries. It is said that the book translated from the Arabic by Robert of Chester in 1144 contains passages which occur in the earlier alchemist mss. It is even probable that the names which figure largely among the early chemists in Europe—Albertus Magnus, Roger Bacon, Raymond Lully, Vincent de Beauvais—are those of writers who made known not so much their own chemical experience as that of the Arabian alchemists. Albertus takes the same view as Avicenna concerning "chemical gold"—it is a superficial imitation, not real gold.

Paracelsus, the son of a physician, studied at Basle and at Würzburg, and after wandering through Europe returned to Basle in 1526 and was appointed professor of medicine. His first public act was to burn the works of Galen and of Avicenna, the great handbooks of medicine, and to proclaim that chemistry was not concerned with the transmutation of metals but was the handmaid of medicine. His reckless use of inorganic salts—many of them poisonous—led to his expulsion from Basle.

Contemporary with the restless and dogmatic Paracelsus, Agricola devoted many years to the study of ores and the preparation of pure metals and salts from them. His *De Re Metallica*

records many first-hand experiments—on the amalgamation process of extracting gold, on the properties of bismuth, on flame-tests for various metals. A little later Libavius, a German physician, published his *Alchymia*, which may be regarded as the first European textbook of chemistry. Coming later still, Glauber made his reputation as a great practical chemist: he gave a clear description of the mineral acids and of *aqua regia* (q.v.), and he left his name attached to sodium sulphate.

Last of the iatrochemists came van Helmont, regarded by many as the link between the alchemists and the modern chemists. He rejected the *tria prima* of Paracelsus and the four elements of Aristotle, going back to the older doctrine of Thales that water was the origin of all things. His well-known experiment of growing a willow-shoot in dried earth, and watering it regularly until it had gained many pounds in weight without receiving any appreciable nutriment except from the water, is recalled now with a feeling that Nature had a sense of irony in deceiving the man who discovered carbonic acid gas.

He showed that an air was given off when an acid acted on limestone or potashes, and that this air extinguished a flame. The same air he found was produced in fermentation and occurred naturally in the Grotto del Cane. In his endeavours to prepare the air in closed vessels he discovered the enormous force developed by it; *Ideo, nominis egestate*, he writes, *halitum illum Gas vocavi, non longe a Chao veterum secretum* (*Opera Omnia*, Frankfurt, 1682, p. 69). The term *gas sylvestre*, applied to carbon dioxide, meant the wild chaotic air that could not be coerced into vessels. Van Helmont found he could make an inflammable air, *gas pingue*, by heating animal matter, but he did not further distinguish between his gases.

BIRTH OF MODERN CHEMISTRY

Boyle.—A new era began with Robert Boyle. In early life, a member of the "Invisible College" (the germ from which the Royal Society sprang), he was drawn in 1654 to Oxford where several of the members were in residence. Here he spent his most active years in experimental research. He established by careful experiments the law known by his name—that the volume of a given mass of air varies inversely as the pressure upon it. He determined the density of air and pointed out that bodies altered in weight according to the varying buoyancy of the atmosphere; and he compared the lower strata of the air to a number of sponges or small springs compressed by the weight of the layers above them. It is notable that not only the facts published by Boyle on the "Spring of the Air," but the very images he used were repeated by Mariotte 14 years later.

In 1661 Boyle published the *Sceptical Chymist*, in which he gravely questions the *tria prima*: "There are some bodies from which it has not yet been made to appear that any degree of fire can separate either salt, or sulphur or mercury, much less all three. Gold may be heated for months in a furnace without losing weight or altering, and yet one of its supposed constituents is volatile and another combustible. Neither can solvents separate any of the three principles from gold; the metal may be added to, and so brought into solution . . . but the gold particles are present all the time: and the metal may be reduced to the same weight, of yellow, ponderous malleable substance it was before."

Boyle gives many instances in which metals, such as lead or copper, may be dissolved in acids and their properties entirely disguised in the compound. The corpuscles of which the metal is composed, meeting with corpuscles of another kind, may be more disposed to unite with them than with the particles forming their original metallic cluster. From the coalition of two different corpuscles a new body may be formed "as really one as either of the corpuscles before they were confounded." We can trace here the modern idea of chemical affinity uniting atoms into compounds. Boyle devised a method for extracting the element phosphorus, which was long known as Boyle's phosphorus; he made many experiments on air and other gases. He prepared hydrogen by the action of acids on steel filings and on iron nails, and showed that it would burn with a strong flame though with little light. He collected the gas in an inverted glass flask over dilute acid, and

showed that the imprisoned gas was permanent and "dilated itself" like air when the vessel was warmed.

In his "New Experiments touching the Relation betwixt Flame and Air" he showed that the flames of hydrogen, of sulphur, and of a candle were extinguished in the receiver of his air-pump when the air was rarified. But, finding that gunpowder and fulminating gold would burn in his vacuum, he was forced to conclude that flame may exist without air: it was left to his assistant Hooke to make the next advance.

By observing that wood-charcoal was immediately dissipated into white ashes if the retort was opened in the air while still red-hot, Hooke grasped the fact that the air "preyed upon" or "dissolved" the charcoal; and he compared the active constituent of the air with that which is fixed in saltpetre. The oil rising as vapour from a lighted wick is not burnt inside the flame (which is dark) but only as it reaches the surrounding atmosphere where it meets the "nitre-air."

Mayow made careful experiments on the burning of combustible bodies in air confined over water. He showed that part of the air disappeared both in combustion and respiration, and that the residue left would not support flame or life. This residue differed then from ordinary air. He did not isolate his nitre-air, nor show what became of it.

THEORY OF PHLOGISTON

The theory of *phlogiston* first proposed by Becher and greatly advanced by Stahl went back to the old idea of Jabir that combustible bodies lost something when they burnt. Becher's *terra pinguis* became Stahl's *phlogiston*, which was not fire itself but the material of fire. Metals were composed of a *calx*, different for each metal, combined with phlogiston, which was the same in all metals and common to all combustibles. When a metal, such as lead or tin, was calcined in the air, phlogiston was evolved and a *calx* was left behind. When a candle or charcoal was burnt in the air it gave off phlogiston (manifest as heat and light) and very little residue was left: wax and charcoal mainly consisted of the material of fire. When a *calx* was heated with charcoal out of contact with air the phlogiston of the charcoal recombined with the *calx* and the metal was re-generated. In this way a generalization was made which accounted for the two opposite processes of oxidation and reduction, and moreover was able to predict certain chemical consequences which were verified later by experiment. The heat given off by animal bodies and its restoration by food were also explained by phlogiston. The fact that combustion and life ceased in a confined volume of air was due to the swift whirling motion of the phlogiston that filled the air, which when saturated could take no more. In considering the wide acceptance of Stahl's theory it must be borne in mind that it gave expression to the very striking facts that in combustion something was emitted by the burning body, viz., *heat*, and in the reduction of a *calx* by charcoal something—potential energy, or the power of giving out heat again—was restored to it.

ANTIPHLOGISTIC EXPERIMENTS

Black and Cavendish.—The first blow to the phlogistic theory was dealt by Black, himself an adherent. It had long been known that limestone was turned into quicklime by heating, and that quicklime brought into contact with the mild alkalis rendered them caustic, returning itself to chalk. This was explained by supposing that the fire gave a "burning principle" to the limestone, which handed it on in turn to the mild alkali. Black, using the balance, found that both chalk and magnesia alba lost weight when they were heated, the loss being due to the escape of a gas previously fixed in them. The caustic lime and magnesia, freed from the gas, no longer effervesced with acids: moreover, the chalk and magnesia alba lost the same weight of gas whether they were strongly heated or were dissolved in an acid. The effervescence was obviously due to the escape of the air. Then an aqueous solution of the caustic lime or magnesia when exposed to the atmosphere gradually formed a white precipitate and lost its causticity as the "Fixed Air" from the atmosphere dissolved in the surface layer of the liquid. Caustic lime and magnesia act

on the mild alkalis by combining with their fixed air, and not by any exchange of phlogiston. Black had proved by quantitative experiments the difference between the mild and caustic alkalis, and had shown that fixed air (CO_2) was a normal constituent of our atmosphere (1756).

Twenty years later Cavendish published his researches on "Factitious Air," in which he described the preparation and properties of carbon dioxide and hydrogen. His work on hydrogen is of the first importance. "Inflammable Air," he found, could be produced readily by the solution of zinc, iron and tin in dilute sulphuric or in hydrochloric acid. He collected and measured the gas over water, and found that a given weight of one of the metals gave the same measure of gas whichever acid was used as the solvent and however diluted the acid. He concluded therefore that the gas came from the metal and was either phlogiston or a compound of phlogiston with water.

Informed of Priestley's observations that in the explosion of inflammable air with common air a dew was deposited on the vessel and a loss of weight ensued, Cavendish carefully repeated the experiments and showed there was no loss of weight, while "almost all the inflammable air, and about one-fifth part of the common air, lose their elasticity and are condensed into a dew which lines the glass." He then burnt a quantity of hydrogen in air and, collecting the dew, found it had the properties of water; the two airs, he said, "are turned into pure water." Then Cavendish fired a mixture of hydrogen and oxygen, and was puzzled for some time by finding the condensed water to be acid. He proved this acid was due to the presence of adventitious nitrogen (from the air) which was acted on in the explosion if the oxygen was in excess. Afterwards he passed electric sparks through a mixture of air and oxygen in a bent tube over mercury in presence of potash. In this remarkable experiment he not only proved the composition of nitre, but proved that the nitrogen of the air could be completely removed with the exception of a small inert bubble of gas about one $\frac{1}{120}$ part of the whole. He had isolated argon (*q.v.*) from the air—by the same method used by Rayleigh and Ramsay more than 100 years later. In spite of the accuracy and the definite plan of his work, Cavendish was not convinced that water was a compound substance; James Watt saw the true significance of his work, and so did Lavoisier when he repeated it.

Scheele and Priestley.—In contrast to the deliberative work of Black and Cavendish, the rapid series of experiments carried out by Scheele in Sweden and by Priestley in England were remarkable for the brilliant observational powers brought into play and for the many discoveries that flowed from them.

Scheele found that various substances—especially bodies like sulphur and phosphorus—diminished the volume of air in which they were burnt; and the residual gas he found, against his expectation, to be lighter than ordinary air, and this lighter portion was no longer able to support combustion. The portion of the air concerned in the burning—his "fire-air" had disappeared. He burnt a jet of hydrogen in a measured volume of air over water, noticed how the flame died out, and then how the water rose in the vessel. Finding no evidence of any change in the water, he concluded that the missing air being neither condensed in the residual "foul air," nor dissolved in the water, must have escaped through the glass. The phlogiston (hydrogen) must have combined with the fire-air to form "caloric," and this had passed through the glass walls. He set himself to reverse the process. If caloric could be passed into a substance avid for phlogiston, the caloric might be broken up, the phlogiston retained and the fire-air liberated. Several bodies, he thought, would strongly attract phlogiston—such as nitric acid, pyrolusite (which he had himself investigated) and the red *calx* of mercury. When heat was applied to nitric acid, red fumes were evolved, and when these were absorbed by lime, a colourless gas remained, which supported combustion brilliantly. He had liberated the sought-for "fire-air." Similarly the *calx* of mercury, when heated in a vessel over a charcoal furnace, combined with the phlogiston of the caloric to form metallic quicksilver and the pure fire-air was set free. He added his fire-air to the residual "foul-air" in due proportion and found the mixture behaved as common air.

Scheele interpreted all his results in terms of the phlogistic theory. Thus when he first isolated chlorine by heating pyrolusite with hydrochloric acid, he imagined the pyrolusite had absorbed phlogiston from the acid, and he named the new gas "dephlogisticated marine acid." We owe to Scheele hydrofluoric, hydrocyanic, arsenic, tungstic and molybdic acids, and a long list of organic substances including glycerine and milk-sugar, with oxalic, tartaric, citric, malic and other acids.

Scheele's discovery of fire-air, probably made in 1773, was not published until 1777. Meanwhile, on Aug. 1, 1774, Priestley had concentrated the sun's rays through his new burning-glass on the red calx of mercury contained in a glass vessel over mercury, and found an air was expelled from it very readily. This air he found was not soluble in water, "but," he writes, "what surprised me more than I can well express was that a candle burned in this air with a remarkably vigorous flame." Now Priestley had previously shown that the respiration of animals acted like burning bodies on common air, diminishing its volume and rendering it noxious. This new air, he found, differed from common air not only in supporting combustion more vividly but in prolonging the life of animals breathing it. His explanation was that while common air is always partially saturated with phlogiston and cannot make room for much more, the new air is uncontaminated and phlogiston can rapidly escape into it—as into a vacuum. He named the new gas therefore "dephlogisticated air," and the residual inert nitrogen he named "phlogisticated air."

Priestley was the first to prepare and describe the gases nitric oxide and nitrous oxide, which he collected over water, and the gaseous hydrogen chloride, ammonia, sulphur dioxide and silicon fluoride, which he collected over mercury.

Lavoisier.—The outstanding feature of Lavoisier's work is the clearness with which he interpreted quantitative results, a clearness founded on his conviction (partly gained from Black) that no ponderable matter disappears in any chemical change. He heated water in a sealed glass vessel for many days, and found the weight of the whole unaltered. On pouring out the water he found the glass had lost in weight, but on evaporating the water he recovered the lost weight in the alkaline silicates which had been dissolved from the glass.

In 1772 Lavoisier began his researches on combustion. When sulphur and phosphorus were burnt in air a portion of the air was fixed. The same thing was observed when lead and tin were calcined in air sealed in glass vessels: there was no change in weight until the vessels were opened and the air rushed in. In 1775, after hearing from Priestley of his "dephlogisticated air," and after repeating the experiment with the red calx of mercury, Lavoisier grasped the true explanation of combustion. The "pure" or "vital" air was combined with the metal in the calx, and this pure air formed that portion of common air which produced calcination by combining with the metal. Then followed the quantitative demonstration that mercury heated in common air slowly combined with the "vital" part and formed the red powder—*mercurius calcinatus*: from this powder, more strongly heated, the vital air was recovered, and this mixed with the inert "azote" (left in the first experiment) exactly reformed the original common air.

Finding that non-metallic elements such as sulphur and phosphorus gave acids when combined with his vital air, and having shown that carbon yielded Black's Fixed Air (Bergman's Aereal Acid), Lavoisier adopted the name oxygen (acid-maker) for the substance which, combined with caloric, formed "oxygen gas." While the non-metallic elements gave acids by their combination with oxygen, the metals gave calces—the oxides of the metals; and the union of the two kinds of oxides gave the various metallic salts. But, the phlogistonists could still object, this did not explain the formation of inflammable air when metals were dissolved in acids. Just the same salt was formed by the union of a calx with an acid as by the solution of the metal in the acid; but in the latter case the metal gave up its phlogiston as inflammable air. Moreover, unless the calx were originally present in the metal, there was no obvious source from which the metal could

obtain the oxygen necessary to form the calx. It was a difficulty only to be solved by Cavendish's proof that water was formed when inflammable air was burnt. Informed of Cavendish's work, Lavoisier and Laplace repeated the experiment and by their correct interpretation supplied the missing data. In the solution of a metal by an acid, the oxygen of the water combines with the metal, liberating the inflammable air—now named hydrogen—whilst the two oxides (the calx and the acid) combine to form the salt. This was the death-blow to the Phlogistic Theory.

Founded on Lavoisier's oxygen theory, a new nomenclature was evolved, and this has largely survived to our day. It was perhaps natural that the new school should consider oxygen to be an essential constituent of all acids, and that the acid from sea-salt, muriatic acid, should be regarded as formed by the union of an oxide of an unknown non-metallic element Murion with water, and that chlorine—Scheele's "Dephlogisticated Marine Acid"—should be an oxygenated compound of this, or "Oxy-muriatic Acid."

CHEMICAL COMBINATION

Berthollet, the most distinguished of Lavoisier's colleagues, was one of the group who drew up the new system of chemical nomenclature. He considered he had a decisive proof that chlorine contained oxygen when he had shown that a solution of the gas in water gave off oxygen when exposed to sunlight, and—gradually losing its colour—was reduced to muriatic acid. It remained for Davy to prove that Scheele's gas contained no oxygen, and that chlorine—the non-committal name suggested by him—was one of a family of elements having acid-forming hydrides.

Berthollet's chief claim to fame rests on his statement of the Law of Mass Action (*see* CHEMICAL ACTION), that the amount of a compound formed by an element A with B or with C depends, not only on the relative affinity of A for B and for C, respectively, but also on the quantities of B and C which are present and in a state to interact with A. This law has been of great importance in theoretical chemistry as well as in manufacturing operations.

But Berthollet carried his doctrine further: he considered that the constancy of composition shown by most known compounds depended on certain conditions prevailing at their preparation. When two elements were combining, a particular composition might correspond with insolubility or volatility, and so this compound might be separated out. Under other conditions the two elements might unite to form compounds in proportions varying between certain limits depending on the active masses of the elements. Berthollet instanced the oxides of lead and of other metals as showing such varying composition. This conception was opposed by Proust, and a long controversy ensued in which it was proved that the "varying" oxides were mixtures of two or more definite oxides, while it was still maintained that liquids such as alcohol and sulphuric acid combined with water in all proportions.

DALTON'S ATOMIC THEORY

Not only were Black and Cavendish clearly convinced that chemical combination took place in definite proportions by weight, but all Lavoisier's work shows his belief in this law. On the other hand, Bergman and his followers had worked on the quantities of acid and base required to form neutral salts, and Richter and Fischer had shown that there was a "reciprocal" law governing the weights of acids and bases which would just saturate each other. The several weights of different bases required to neutralize a given acid were also the weights required to neutralize a constant but different weight of another acid. This law of neutrality, embodied later in the "Law of Reciprocal Proportions," received little recognition at the time: it was revived to give support to and be explained by the Atomic Theory.

Dalton first briefly announced his theory in a memoir on the solubility of gases in 1803. He was led back to the old hypothesis of atoms through his study of the physical behaviour of gases, for he states that *the solubility of a gas depends upon the weight and number of the ultimate particles of the gas*. Already in 1801 he had shown experimentally that different gases under the same pressure expanded equally by heat, and had concluded that "all

elastic fluids" did the same; this fact he attributed to the expansion of a gas being entirely due to repulsion between the separated particles caused by heat alone, independently of any chemical attraction between them such as is shown in liquids and solids. His laboratory note-books show that Dalton had the idea of atoms in his mind some time before 1803, and the first table as published (in 1805) differs from the earliest tables found in his notes, but the essential facts are the same—if the weight of an atom of hydrogen is 1 a definite relative weight may be assigned to each atom of another element and to each compound atom formed by the union of these elementary atoms.

Dalton's table of the relative weights of the ultimate particles of gaseous and other bodies

| | | |
|----------------------|-----------------------------------|--------------------------------|
| Hydrogen . . . 1 | Nitrous gas . . . 9.3 | Carbonic acid . . . 15.3 |
| Azote . . . 4.2 | Ether . . . 9.6 | Alcohol . . . 15.1 |
| Carbon . . . 4.3 | Gaseous oxide of carbon . . . 9.8 | Sulphureous acid . . . 19.9 |
| Ammonia . . . 5.2 | Nitrous oxide . . . 13.7 | Sulphuric acid . . . 25.4 |
| Oxygen . . . 5.5 | Sulphur . . . 14.4 | Carburetted hydrogen . . . 6.3 |
| Water . . . 6.5 | Nitric acid . . . 15.2 | Olefiant gas . . . 5.3 |
| Phosphorus . . . 7.2 | Sulphuretted hydrogen . . . 15.4 | |

The Law of Multiple Proportion is clearly embodied in this table (in spite of mistakes in the weights given for nitrous "gas" and "oxide"). The two compounds of carbon with oxygen, the two compounds of sulphur with oxygen, and the two compounds of carbon with hydrogen are represented by the sum of their atomic weights—CO and CO₂, SO and SO₂, CH₄ and CH.

Taking, as Dalton did, a fixed weight of one element in two or more compounds formed by it with another, then the weights of the second element which combine with the fixed weight of the first are simple multiples of each other. Dalton seems to have sought for instances of this chemical law to support the theory he had conceived on other grounds. Dalton published the full theory in his *New System of Chemistry* (1808), representing his atoms by circles—○ for hydrogen, ⊙ for nitrogen, ● for carbon, ○ for oxygen, etc., and placing these symbols to touch one another in compounds; e.g., ○○ for water, ○● olefiant gas, ○●○ marsh gas.

Dalton laid down certain rules for determining atomic weights, remarking that one must always presume where only one compound is known that it is a *binary* one, and that such compound should always be specifically heavier than the mixture of its two ingredients.

Dalton's theory was soon adopted, and elaborate researches were made—especially by Berzelius—to determine by analysis the correct atomic weights. One of the first changes in Dalton's weights was due to Davy's decomposition of soda and potash by the electric current, and the recognition that the alkaline earths were also oxides of metals.

In 1808 Gay Lussac announced his law that *gases when they combine do so in very simple proportions by volume*, and the product formed, when gaseous, also occupies a volume simply related to those of its ingredients. Hydrogen unites with chlorine in equal volumes, and the acid gas formed occupies the same volume as the two; similarly two volumes of hydrogen unite with one volume of oxygen to form two volumes of steam measured under the same conditions. In such facts Gay Lussac saw a strong confirmation of Dalton's theory: assuming that the atoms of his gases occupied the same space, the volumes in which the gases combined ought to be simply related. But the idea that different atoms occupied the same space was repugnant to Dalton, who pointed out that steam was lighter than oxygen, and therefore in forming steam, according to Gay Lussac's idea, the oxygen atom must have divided itself.

The difficulty was overcome by *Avogadro's Hypothesis* (1811) that the chemical particles occupying the same gaseous volume were not single atoms but molecules consisting of 2 atoms, and in the formation of steam the oxygen molecule had divided itself between two hydrogen molecules. That "*equal volumes of all gases, simple or compound, contain the same number of molecules*" was in agreement both with physical and chemical data. This

generalization, however, was long opposed by Berzelius, who could not reconcile the diatomic molecule of a simple element with his electro-chemical theory: moreover, the vapour densities of elements such as sulphur and phosphorus appeared anomalous.

With regard to the atomic weights of the metals the law of Dulong and Petit (1819) that "*the specific heats are inversely proportional to the atomic weights*," and the law of Mitscherlich (1820) that "*salts having the same crystalline forms have similar chemical constitutions*" were of great assistance: but in spite of much detailed progress great confusion existed in the use of different "equivalents" and atomic weights. Order was only restored by the reform advocated by Cannizzaro (1858), who insisted that the atomic weight deduced from the weight of the gaseous molecule agreed with that calculated from the specific heat, and should be adopted.

Meanwhile, the elements had been grouped into families some of which showed marked resemblances between their members. Moreover, it was observed that the members of a family showed a regular gradation in their chemical and physical properties and in their atomic weights. Dumas drew attention to several such "triad" groups and showed that the central element was nearly the mean, in weight and properties, between the first and third; for instance sodium was half-way between lithium and potassium; bromine half-way between chlorine and iodine; selenium half-way between sulphur and tellurium; strontium half-way between calcium and barium. Elements seemed to be cast in certain moulds. Similarly, the formulae of compounds were built up on certain simple types. The use of the water-type by Williamson and of the ammonia-type and methane-type by Hofmann did much to explain similarities in chemical reactions, and led to the recognition of the different valencies of the elements. That atoms had valencies or bonds by which they attached themselves to each other, and that one atom differed from another in this power, gave a reason for the several types—if it was assumed that elements like hydrogen had one valency, others like oxygen had two, and so on. Frankland, who introduced this conception, accounted for elements having varying valencies by supposing that two of the bonds might be mutually satisfied, so that a pentad atom like =N≡ (with five bonds) might also act like a triad by the self-junction of two bonds, <N≡.

CLASSIFICATION OF THE ELEMENTS

As early as 1815 Prout put forward the view that all the elements were compounded of hydrogen, and all the atomic weights were simple multiples of that unit. That so many of the atomic weights approached whole numbers very closely seemed to exclude that this was a mere chance coincidence; but on the other hand there were well-established cases, such as chlorine, where the weight could not be reconciled with Prout's hypothesis. It was only after Cannizzaro's reform that a "natural" arrangement of the elements became possible. A scheme due to de Chancourtois in 1862 was followed by the law of Octaves published by Newlands in 1864. The latter placed all the known elements in eight vertical columns of seven each in the order of their weights, the second column starting with fluorine, the third with chlorine, and so on. Neither of these arrangements was accepted by chemists, although they both embodied the idea that carried conviction when put forward, quite independently, by Mendeleev in 1869.

In the Periodic Classification (*q.v.*) Mendeleev showed how regularly the elements changed in character as they changed in weight until the end of each "period" was reached, when by a sudden leap the character of the first was reproduced. In some doubtful cases he assigned atomic weights so that the elements should fit their places. Moreover he left many blank places to be filled, and was able to predict in some cases the atomic weight and the chief properties of the undiscovered element. His predictions were most startlingly fulfilled in the discovery of gallium, scandium and germanium.

The discovery of the inert gas, argon, by Rayleigh and Ramsay in 1894, and their proof that its molecule contained a single atom only, appeared at first at variance with the Periodic System.

But when Helium was discovered Ramsay was able to place these two gases as transitional elements and to predict another member of this family with an atomic weight between those of fluorine and sodium. By an exhaustive series of fractional distillations of the argon residues from air he and his colleagues separated first Neon and finally the two heavier gases Krypton and Xenon. These gases, like helium and argon, are chemically inert, and like them are monatomic. The chemical inertness of these elements has been explained, on the electron theory, by the symmetry of the orbits of their valency-electrons.

The proved success of the Periodic System both in co-ordination and prediction of chemical facts naturally led to the conviction that either its "weight" or its "place" held the secret of an element's properties. Many attempts were made to show "multiple" relations between the atomic weights, but no real advance was made until new discoveries in physical chemistry gave fresh views as to the ionization of salts in solution, the nature of electric discharges in gases, and the mechanism of radioactivity (*q.v.*).

IONS AND ELECTRONS

J. H. van't Hoff first explained osmotic pressure, the molecular depression of the freezing-point and raising of the boiling-point of solutions by showing that in dilute solution substances behaved like a gas. This conception was widened by S. Arrhenius and W. Ostwald, who concluded that salts and strong acids in aqueous solution were dissociated into charged ions, and the electric conductivity of the solution measured the number of such ions. The theory of electrolytic dissociation has given a consistent explanation of a great number of observed facts concerning solutions, and familiarized the idea of a mobile hydrogen atom bearing a unit charge of positive electricity. After Crookes' pioneering work on discharges in high vacua—his "fourth state of matter"—the discovery of the Röntgen rays in 1895, and of the radioactivity of uranium in 1896 opened a new era. In 1897 J. J. Thomson showed the independent existence of "gaseous" electrons as electrified units with a mass very minute compared with the lightest atom known; and since the same electrons were produced from different elements, he inferred that all atoms might be built up of these minute electrons. The charge carried by a gaseous ion was proved to be equal to that borne by the hydrogen ion in electrolysis.

The separation of radium salts from uranium ores by the Curies in 1898 revealed that the uranium was undergoing a spontaneous transformation through a succession of atomic explosions giving out radiations of three kinds—the heavy α -particles, the β -electrons and the γ -high-frequency waves. That the α -particles shot out from radium were atoms of helium was shown in Ramsay's laboratory in 1903.

Then followed Rutherford's achievement in counting the individual helium atoms shot out in unit time from a disintegrating element, from which he could deduce the actual number of atoms and molecules of any gas in a defined volume. The speed of the rejected α -particle showed the intense internal energy of the disintegrating atom, and the use of this "projectile" to probe other atoms led to the conception of an atom as composed of a heavy but very small positive nucleus, round which the inner electrons revolved with enormous rapidity, while the orbits of the outer electrons, circular or elliptical, were far removed from the positive focus (*see* ATOM).

ATOMIC NUMBERS

It was from the study of the X-ray spectra of various elements, all exhibiting bright lines similar in type, that H. G. J. Moseley was led to his Atomic Numbers. The vibration-frequency of these lines varied as the squares of whole numbers which advanced by one unit as the series of elements was ascended.

This series of whole numbers when applied in order to the elements in the Periodic Table, beginning with H=1, gives the number of units of positive electricity in the nucleus and the number of negative electrons round the nucleus required to neutralize them, thus fixing the number of electrons attached to each element—a number ranging from one in the hydrogen atom

to 92 in the uranium atom. The atomic numbers in this system are more fundamental than the atomic weights, for the properties of the elements depend directly upon them. The Table of Atomic Numbers could, like the Periodic Table, claim the power of successful prediction, for the element hafnium (celtium) (*q.v.*), subsequently discovered, filled the vacancy left at No. 72.

The breaking down of radioactive elements such as uranium and thorium by the successive losses of a helium atom to produce in many cases substances which appeared to have almost identical chemical characters, and the natural occurrence of groups of elements of similar character and approximately equal atomic weights, led F. Soddy and K. Fajans, quite independently of each other to formulate the theory of isotopes (*q.v.*), *i.e.*, of elements having the same number in the atomic order, but having different atomic weights. If, for instance, both uranium and thorium lose helium atoms until they reach a stable form in lead, it might be conjectured that two forms of lead could be found—associated with different minerals—differing only in atomic weight. Chemical analyses have shown such differences in lead from different sources, so that it is permissible to regard ordinary lead as a mixture of two isotopes. This conclusion is much strengthened by the actual separation by F. W. Aston of the positively charged atoms travelling to the negative pole in the case of many of the simpler elements, of which neon formed a striking example. Similarly Aston was able to show that ordinary chlorine contains at least two isotopes differing by two weight-units. In all the cases examined, Aston found the weights of each isotope to be close to a whole number.

Lastly Rutherford, using the newly ejected helium atom as his shell, and C. T. R. Wilson's water-laden gas as marker, has shown that certain elements of low *uneven* atomic number yield on bombardment a swiftly moving atom which is conjectured to be hydrogen. Elements of *even* number are not so attacked. The inference is that elements such as nitrogen may contain hydrogen atoms in or close to the nucleus, whilst the even elements are built up of helium atoms, in each of which four hydrogen atoms are so packed that they have lost a portion of their mass.

In Bohr's theory of the genesis of atoms, it is assumed that electrons are bound on successively to a nucleus originally naked. If such a synthesis begins in the interior of a star by the coalescence of four hydrogen atoms into one helium atom weighing less than its four components, there must be a definite loss of mass (energy) which might maintain the heat and radiation of the star. Again, if the outer electrons failed to join up, or were stripped off in the turmoil of the stellar centre, matter far denser than any of our elements might be formed. Of such condensation of matter there is astronomical evidence in *dense* stars—such as the Companion of Sirius.

INORGANIC CHEMISTRY

Inorganic Chemistry, which is concerned with the preparation and properties of the elements and non-carbon compounds, was primarily developed through the investigation of minerals, and was in consequence termed mineral chemistry, whereas organic chemistry resulted from the study of plant and animal products. Though it was well recognized that organic substances were amenable to the same general chemical laws as mineral substances, it was not found possible, prior to 1828, to prepare organic substances from the elements synthetically, and it was supposed that a fundamental difference existed between organic

and inorganic substances. In 1828, F. Wöhler's synthesis of urea imparted a great impetus to the study of organic substances, and within a few years it was found convenient to separate chemical science into the domain of the carbon compounds, organic chemistry, and that of the elements and non-carbon compounds, inorganic chemistry. It is usual and convenient, however, to include in inorganic chemistry the oxides and nitride of carbon and their simpler derivatives, such as metallic carbonyls, carbonates and cyanides.

Early Discoveries.—The earliest discoveries in inorganic chemistry were made in the metallurgical and medical arts and in the domestic economy of the ancients. Gold, silver, copper, tin, iron and lead, some of the simpler alloys, metallic salts and mineral products, and the rudiments of metallurgical, glass-making, enamelling, painting, dyeing, alchemical and medical arts were known to the ancient Chaldeans, Hindus, Chinese, Egyptians and Greeks, many centuries before the Christian era. By about the middle of the 17th century, the alchemists were acquainted with most of the common metals, their alloys and salts, a few acids, alkalis, medicinal minerals, and non-metallic elements. In 1733 G. Brandt of Sweden isolated cobalt, and in 1750 A. F. Cronstedt prepared metallic nickel. These discoveries were followed by Henry Cavendish's recognition of elementary hydrogen in 1766, the isolation of nitrogen by Daniel Rutherford in 1772, manganese by J. G. Gahn in 1774, oxygen by Joseph Priestley and chlorine by K. Scheele in 1774, and molybdenum by P. J. Helm in 1782. Cavendish in 1784 made the far-reaching discovery that water is composed of two volumes of hydrogen to one of oxygen, and in the following year he succeeded in synthesizing nitric acid by passing electric sparks through moist air. His further discovery, that a minute residue of the air would not combine with oxygen, was ignored for over a century, until Lord Rayleigh and Sir William Ramsay in 1895 proved that the inert residue consists of a mixture of the noble gases, argon, krypton, neon and xenon.

The mineral pitchblende, in which M. H. Klaproth detected uranium in 1789, is of great historical importance, for W. F. Hillebrand exactly a century later obtained from it a gas which he supposed was wholly nitrogen, but which Ramsay in 1894 proved was a mixture with about 12% of the noble gas, helium, first detected spectroscopically in the sun by E. Frankland and Sir J. N. Lockyer in 1868. Henri Becquerel's detection in 1896 of the emission of radiation by uranium salts from pitchblende, led to the epoch-making discovery in 1898 of the radioactive compounds of polonium and radium by Marie and Pierre Curie, and of the heaviest noble gas, radon, by Ernst Dorn in 1900 (*see* RADIOACTIVITY).

Zirconium was detected by Klaproth in 1788, and titanium by McGregor in 1791. Don Fausto d'Elhuyar isolated tungsten in 1794, though the existence of tungstic acid had been proved by Scheele 20 years earlier. In 1794 J. Gadolin discovered the "rare earth" yttria, the chief constituent of the mineral later called gadolinite found in Ytterby in Sweden. The "rare earth" group of closely allied elements has been the subject of intensive chemical research for over a century. Cerium was detected simultaneously and independently by Klaproth, J. J. Berzelius and W. Hisinger in 1803. C. G. Mosander detected lanthanum in 1839, "didymia" in 1841 and terbium and erbium in 1843. "Ytterbia" was detected by J. C. G. de Marignac in 1878, scandium by Lars F. Nilson in 1879, samarium in the same year by Paul E. Lecoq de Boisbaudran and also holmium and thulium by P. T. Cleve. Mosander's "didymia" was resolved in 1885 into praseodymia and neodymia by Carl Auer von Welsbach, and G. Urbain resolved Marignac's "ytterbia" into ytterbia and lutecia in 1907. In 1886 Lecoq de Boisbaudran detected dysprosium and, with Marignac, gadolinium. The radioactive element actinium, the heaviest of the "rare earth" series, was detected by A. Debierne in 1899. The gap in atomic number between neodymium (60) and samarium (62) was filled in 1926 by the discovery of illinium by X-ray spectroscopy by J. A. Harris, L. F. Yntema and B. S. Hopkins, thus completing the series of "rare earth" elements. These eighteen elements are all proper to group III, of the

periodic classification (*q.v.*), scandium to period 4, yttrium to period 5, the 15 elements from lanthanum to lutecium to period 6 and actinium to period 7.

Platinum was probably known to the natives of Mexico and South America many centuries before its recognition by Scalinger in 1558 and William Brownrigg's description of it to the Royal Society in 1750. W. H. Wollaston discovered palladium in 1803 and rhodium in 1804. In the following year Smithson Tennant discovered iridium and osmium. The lightest of the "platinum metals" was not discovered till 1826, when Osann claimed to have isolated three new elements in native platinum alloys from Ruthenia in Russia. C. E. Claus was able to confirm the existence of only one of these new elements, which he called ruthenium.

Beryllium and chromium were detected by L. N. Vauquelin in 1797, and in the following year Klaproth isolated tellurium. Its congener, selenium, was not discovered till 1817, when Berzelius detected it as a red deposit in Swedish sulphuric acid chambers. In similar seleniferous deposits in German sulphuric acid works, Sir William Crookes in 1861 discovered thallium, the heaviest metal of the aluminium family.

The beginning of the 19th century witnessed the discovery of the most powerful method for the analysis of compounds into their elements, that of electrolysis. By this means Sir Humphry Davy was enabled to decompose the supposed elements, soda and potash, and isolated the metals sodium and potassium in 1808. Shortly afterwards he obtained magnesium, calcium, strontium and barium from magnesia, lime, strontia and baryta respectively. The discovery of boron by J. L. Gay Lussac and Davy in 1809 led Berzelius to investigate the supposed element, silex or silica, which he proved in 1810 to be the oxide of a new non-metallic element, silicon. The element was obtained by the reduction of fused silica with carbon and iron, and was finally obtained pure in 1823 after Berzelius had discovered the general method of reduction by heating potassium double fluorides with potassium. Using the new method he isolated zirconium in 1824, titanium shortly afterwards and thorium in 1828. A similar but more accessible method was introduced by Wöhler in 1827, beryllium and aluminium being isolated by heating their chlorides with potassium.

In 1812 B. Courtois isolated the element iodine from the ashes of marine plants. The analogy of iodine to chlorine was quickly recognized, and in 1815 Gay Lussac isolated cyanogen, a compound which in combination behaves very similarly to the halogen elements, chlorine and iodine. Bromine, intermediate in atomic weight and properties between chlorine and iodine, was discovered by A. J. Balard in 1826. The lightest of the halogen family of elements, fluorine, though well recognized as an element, resisted numerous attempts to isolate it until 1886, when Henri Moissan obtained the elementary gas by the electrolysis of a solution of potassium hydrogen fluoride in hydrofluoric acid in a platinum vessel.

The lightest of the alkali metals, lithium, was discovered by Arfvedson in 1817, but the two heaviest, rubidium and caesium, were not detected till 1861 and 1860, respectively, when Robert W. Bunsen and G. R. Kirchhoff applied spectrum analysis to the detection of elements, a new method discovered by them in 1859. This method has been of immense service in chemistry, and has led to the discovery of thallium by Crookes, indium by F. Reich and H. T. Richter in 1863, and gallium by Lecoq de Boisbaudran in 1875, all members of the aluminium family. The spectroscopic method has also played an important part in the characterization of the "rare earths," and has proved of fundamental importance in ascertaining the composition of the sun and stars. Its extension to X-ray spectra has in recent years led to great advances in physical knowledge of the structure of atoms.

Vanadium was discovered by Del Rio in 1801, and the allied element, niobium (columbium), by C. Hatchett in the same year. Tantalum, the next heavier member of this family, was discovered by A. G. Ekeberg two years later, but Wollaston in 1809 pronounced niobium and tantalum to be identical. These elements were not separately distinguished until 1844, when H. Rose showed that the mineral columbite contained two distinct elements, the lighter of which he named niobium and the heavier

tantalum. Nevertheless, confusion continued to exist between these elements till Marignac proved in 1866 that Rose's niobium was in fact Hatchett's columbium. The separation of these elements is one of the most difficult problems of analytical chemistry, most methods being based on slight differences in solubility or hydrolyzability of their double fluorides. The radioactive element, protoactinium, is the heaviest of the vanadium family, and was discovered by Otto Hahn and Lise Meitner in 1918. The atomic weight of protoactinium is uncertain and its atomic number is known only by inference from the radioactive disintegration series.

FORMULAE AND NOMENCLATURE

A chemical formula is a collection of letters and numerals indicating the elementary composition of a compound substance. The symbol for an atom of an element is either the capital letter of its English or Latin name, as C for carbon and K for potassium (Latin, *kalium*), or the capital letter followed by a small letter, as Co for cobalt and Cr for chromium. The qualitative composition of a compound substance is indicated by a formula consisting of the symbols of the elements in juxtaposition, as CO for carbon oxide. Chemical formulae, however, convey quantitative as well as qualitative composition. Empirical formulae indicate the component elements and the simplest ratio between them, as Fe_2O_3 for iron oxide, the subscript numerals signifying a ratio of two atoms of iron to three of oxygen. Rational formulae indicate further the actual number of atoms of each element in one compound molecule, *i.e.* in the smallest portion of the compound that can exist as a separate entity. The empirical formula of acetylene, for example, is CH, but the rational formula is known to be C_2H_2 . Empirical and rational formulae are, however, often identical. A chemical formula generally attempts to show the scheme of combination between the various atoms comprising a molecule. For example, the rational formula of thorium sulphate is Th_2SO_4 , but is usually rearranged as $\text{Th}(\text{SO}_4)_2$, the subscript numeral 2 indicating that two SO_4 or sulphate groupings are separate radicals independently in combination with one atom of thorium. Rational formulae thus rearranged as structural formulae are in general use, particularly in organic chemistry, and conventional schemes have been adopted to convey the *exact* mode of combination in compounds with many different identifiable radicals.

By common agreement, the names of compounds of atoms of two elements are formed from the name of the electro-positive element followed by the name of the electro-negative element inflected by the suffix *ide*, as in sodium chloride, calcium oxide, zinc sulphide. When two elements form more than one compound, Greek numerical prefixes are generally used to inflect the electro-negative term, as in carbon monoxide, carbon dioxide, phosphorus trioxide and phosphorus pentoxide. The Latin prefix *sesqui* is, however, used to indicate one and a half, as in the case of chromium sesquioxide (Cr_2O_3), in order to distinguish it from chromium trioxide (CrO_3). Elements, which form more than one oxide and give rise to corresponding series of salts, have the different series distinguished by an inflecting suffix to the electro-positive term, the numerical prefix to the electro-negative term being omitted. The suffix *ous* is used to indicate the lower and the suffix *ic* to indicate the higher condition of oxidation, as in the copper compounds, cuprous oxide (Cu_2O), and cupric oxide (CuO).

Oxides may be classified as acidic or basic, according to whether they neutralize bases or acids. Acidic oxides on solution in water give rise to acids, sulphur dioxide (SO_2), for example, combining with water to form sulphurous acid (H_2SO_3). The more highly oxygenated sulphur trioxide (SO_3) yields sulphuric acid (H_2SO_4). The terminations *ous* and *ic* are generally used to distinguish the acids derived from the lower and higher acidic oxide. Basic oxides also usually combine with water, but form bases not acids, basic barium oxide (BaO), for example, combining with water to form the base, barium hydroxide [$\text{Ba}(\text{OH})_2$]. When acids and bases neutralize one another water is eliminated and the same salt is formed as by the combination of the basic and acidic oxide. Barium hydroxide, for example, combines with sulphurous acid to form the salt, barium sulphite (BaSO_3), the product of the combination of barium oxide and sulphur dioxide. Similarly, barium hydroxide and sulphuric acid yield barium sulphate

(BaSO_4), the product of the combination of barium oxide with sulphur trioxide. The terminations *ite* and *ate* are used to indicate the salts derived from acids terminating in *ous* and *ic*, whereas the termination *ide* is used for salts and compounds in general formed from only two elements, as in the case of oxide, chloride and sulphide. If more than two series of acidic oxides, acids and salts are derived from an element, the inflecting prefix *hypo* is used for the series lowest in oxidation, and *per* for the series highest in oxidation, as in the case of hypochlorous, chlorous, chloric and perchloric acids, and hypochlorites, chlorites, chlorates and perchlorates. As acidic oxides are derived from acids by abstraction of water, such oxides are alternatively referred to as anhydrides, particularly in organic chemistry.

A few oxides and hydroxides are at once basic and acidic, combining with either acids or bases, and are termed *amphoteric*. Aluminium oxide, for example, is amphoteric in yielding aluminium salts with acids and aluminates with bases, as in the case of aluminium nitrate and sodium aluminate.

The oxygen of acids is replaceable in whole or in part by other elements allied to oxygen, for example sulphur. If one oxygen atom in a sulphate, for example, be replaced by a sulphur atom, the product is a thiosulphate (*theion*, sulphur), as in the case of sodium thiosulphate ($\text{Na}_2\text{SO}_3\text{S}$ or $\text{Na}_2\text{S}_2\text{O}_3$). Similarly the replacement of the oxygen by sulphur in potassium carbonate gives potassium thiocarbonate (K_2CS_3).

The capacity of an element for combination is not exhausted by simple salt formation by reaction of its oxide or hydroxide with acids. Aluminium sulphate, $\text{Al}_2(\text{SO}_4)_3$, for example, is the salt formed by the reaction of aluminium hydroxide with sulphuric acid, but this salt combines, molecule for molecule, with potassium sulphate K_2SO_4 , and water to form a double salt, alum, $\text{Al}_2(\text{SO}_4)_3 \cdot \text{K}_2\text{SO}_4 \cdot 24\text{H}_2\text{O}$, which has many analogues (*see* ALUM). Diverse double salts are furnished by other metals in combination with acidic radicals other than sulphates. Magnesium chloride, for example, combines with potassium chloride and water to form the double chloride, carnallite ($\text{MgCl}_2 \cdot \text{KCl} \cdot 6\text{H}_2\text{O}$). The combination between the simple salts in double salts is, however, relatively loose, and the salts are split into their components often merely by solution in water, and the various metallic and acidic radicals are readily detected by the usual analytical tests. In other types of similar compounds, however, the union between the component simple salts is very much closer, and frequently the compounds are not readily decomposed into their components by the usual reagents. Such compounds are referred to as complex salts, and in these cases two or more of the component radicals, acidic or metallic, cannot be detected by the usual analytical processes. The compound of sodium chloride and platinum chloride, sodium platinichloride or chloroplatinate (Na_2PtCl_6), for example, is soluble in water without decomposition and yields none of the ordinary analytical reactions of either chlorides or platinum salts. The complex salt, potassium ferrocyanide [$\text{K}_4\text{Fe}(\text{CN})_6$ or $\text{Fe}(\text{CN})_2 \cdot 4\text{KCN}$], similarly gives none of the usual analytical reactions of cyanides or iron salts.

A new viewpoint of the constitution of these and many other complex compounds was put forward by Alfred Werner in 1891 and 1893 by the promulgation of his theory of co-ordination (*q.v.*), in which the valency of an atom was regarded as distributed in space around the atom and thus partly available for binding atoms other than those primarily engaged in the principal valency combination (*see* AMINES).

The simplest inorganic compounds are the hydrides, compounds of the elements with hydrogen, but until recent years comparatively few hydrides had been prepared and investigated. The hydrides of the halogen elements, such as hydrogen chloride (HCl), and the hydrides, water, sulphuretted hydrogen (H_2S), and methane (CH_4), have been known for centuries. The phosphorus, arsenic and antimony hydrides analogous to ammonia (NH_3) have long been known, but the corresponding bismuth and polonium hydrides were discovered by F. Paneth only in 1918. The hydrides of tin and lead were discovered by Paneth two years later, and are probably analogous to methane, silane and germane, the last of which was discovered by E. Vogelen in 1902, though its composition as germanium tetrahydride was not established till 20 years later by Paneth. It is a curious fact that the

gaseous hydrides of the elements (except boron) are confined to groups IV., V., VI. and VII. of the periodic classification (*q.v.*) the hydrides of the alkali metals, the alkaline earth metals, the "rare earth" metals and of thorium and copper all being solids. The hydrides of chromium, cobalt, nickel and iron are also solids. Though hydrides of boron have been known for half a century, their composition was uncertain till 1913, when Alfred Stock commenced his extensive researches on the hydroborons. The simplest hydroboron is diborane, B_2H_6 , other hydrides having the formulae B_2H_{10} , B_3H_8 , B_3H_{11} , B_4H_{10} and $B_{10}H_{14}$. Owing to the presence of an odd number of hydrogen atoms in some of these hydrides, their formulation is impossible on the ordinarily accepted theories of valency. The existence of these compounds appears to demand the abandonment of the usual conception of valency, and the substitution of the actual number of electrons participating in each chemical bond. It is usual to postulate an invariable valency bond of two shared electrons, and it is almost certain that this type of bond is common to the majority of organic compounds. Evidence is accumulating, however, that this type of bond is not general in inorganic chemistry, particularly in the case of the more reactive non-ionized compounds, and a bond of a single shared electron appears to accord better with the experimental evidence.

Each element is described, together with its commoner compounds, under its own heading.

ORGANIC CHEMISTRY

Organic chemistry, in its modern sense, is the chemistry of all carbon compounds. Carbon, occupying a position in the periodic table between the metals and non-metals, is capable of combining with a large number of elements having widely varying chemical properties, and, in addition, has the special property of combining with itself to an unlimited extent. The result is that the carbon compounds are so numerous that a special branch of chemistry is devoted to their study. Usually, however, the simpler compounds, such as the oxides, cyanogen, etc., are dealt with under inorganic chemistry, and organic chemistry is reserved for the extensive treatment of the more complicated compounds, including those existing in living matter.

HISTORICAL INTRODUCTION

Whereas inorganic chemistry originally arose from the examination of the metals and mineral or earthy materials, the organic side was developed by the study of substances of vegetable and animal origin. The beginnings of organic chemistry were hindered by the alchemists' quest for the philosopher's stone, which should transmute the base metals into gold, and for the elixir of life, a universal medicine to confer immortality, or at least, longevity upon those who drank it. The iatrochemists in the 16th century confined their attention chiefly to the search for medicinal products, which included a study of the distillation of such materials as herbs and resins. The only general classification of substances, based on their physical and superficial properties, led to the correlation of organic and inorganic compounds without regard to their chemical characteristics. All organic substances were grouped with the combustibles in the period of the phlogistic theory.

Development of organic chemistry in the 18th century was confined to improvements in a few practical applications, especially in the arts of medicine and dyeing. It received some impetus from the work of Karl Wilhelm Scheele, and later from that of Michel Eugène Chevreul, who showed the general occurrence of

glycerine and fatty acids in all oils and fats, both of vegetable and animal origin. Theoretical speculation was revived by Antoine Laurent Lavoisier, who, after explaining the true nature of combustion, and devising methods of analysis, concluded that vegetable substances in general contained carbon, hydrogen and oxygen, whilst animal substances contained, in addition, nitrogen and sometimes phosphorus and sulphur.

It is well said that the mechanism of chemical combination is the ultimate problem of chemistry, and theories regarding it were propounded even prior to the advent of the atomic theory. In 1787, Guyton de Morveau suggested that all compounds consisted of oxygen combined with a *base*. Lavoisier went further and considered inorganic compounds to be oxides of simple substances, and organic compounds, oxides of complexes or *radicals*. He had observed that some elements were capable of forming more than one oxide, and concluded that organic radicals acted similarly. He thus regarded sugar as a neutral oxide of a hydrocarbon radical (a complex consisting of carbon and hydrogen), and oxalic acid as a higher oxide of the same radical, since it was formed from sugar by treatment with the powerful oxidizing agent nitric acid. Lavoisier considered all radicals as bases, but the latter term was later restricted to the oxides of metals.

There was, at this time, a wide-spread belief, held until much later by Jöns Jacob Berzelius, Leopold Gmelin and others, that the formation of organic compounds was conditioned by the intervention of a so-called *vital force*, a force which could not be imitated for the purpose of a laboratory synthesis. Berzelius was of the opinion that in the sphere of living nature the elements obeyed laws totally different from those ruling in inanimate material. In fact, he stated (1811) that the composition of the majority of organic compounds appeared to be inconsistent with the requirements of the ordinary laws of simple and multiple proportions. Improved appliances and methods of analysis convinced him (1813–14) that, although they possessed much more complicated compositions than the mineral compounds, they did, in fact, follow the simple laws applicable to the inorganic world. The first real blow to the vitalist theory was the synthesis, by Friedrich Wöhler (1828), of urea from ammonium cyanate. Urea, a product of animal metabolism, was thus obtained from a compound hitherto regarded as truly inorganic.

Theories of Organic Radicals.—Berzelius adopted Lavoisier's view that organic compounds were oxides of compound radicals, and contained, therefore, at least three elements: carbon, hydrogen, and oxygen. This view was acceptable to Gmelin, who, in his book of 1817, described inorganic compounds as being of *binary* composition, and organic compounds as *ternary*. Consequently, marsh gas, ethylene and cyanogen were regarded as inorganic. This binary conception received apparent support from the inference by Louis Joseph Gay-Lussac (1815) that alcohol and ether could be regarded as water coupled with one and two particles of ethylene respectively. Gay-Lussac examined the cyanogen compounds and showed that the cyanogen group was an unvarying radical which persisted throughout a series of compounds. As a consequence of these observations, numerous attempts were made to find other radicals which would function as elements.

At this stage another problem was introduced into organic chemistry, namely, to account for the occurrence of two or more substances with similar percentage compositions, but dissimilar chemical and physical properties. John Dalton (1820) discovered a hydrocarbon in oil-gas having the same percentage composition as ethylene (C_2H_4), and it was later suggested that it consisted of two ethylene particles (the formulae in brackets represent the correct modern version). This was confirmed by Michael Faraday (1825), who called the gas butylene (C_4H_8). Justus von Liebig (1823) announced that his analysis of silver fulminate gave the same results as those ascribed to silver cyanate by Wöhler in the previous year. Berzelius (1826–27) followed up Gay-Lussac's suggestion that the difference in properties of these substances with the same percentage composition must be due to differences in the arrangements of the same relative numbers of the same atoms, a suggestion which gained ground with Wöhler's urea synthesis, but it was not until 1832–33 that Berzelius finally accepted

this doctrine, which he called *isomerism*.

Jean Baptiste André Dumas and Polydore Boullay (1827) put forward the theory that ether and the simple derivatives of ethylene all contained the ethylene group, $C_2H_4(C_2H_4)$, for which Berzelius proposed the name *etherin*. Liebig, however, adopted the dualistic view and regarded ether as the oxide of the radical $C_4H_{10}(C_2H_5)$, which he called *etheryl* or *ethyl*, and alcohol as the hydrate of ethyl. He was wrong, since he attributed to alcohol twice its true molecular weight, but despite this and similar errors, the value of the *Ethyl Radical Theory* was recognized. In 1832, Wöhler and Liebig published their outstanding researches on the radical of benzoic acid, and showed that the radical containing carbon, hydrogen and oxygen (C_6H_5CO), which they named *benzoyl*, formed the basis of benzaldehyde, benzoic acid, benzoyl chloride, benzoyl bromide, and benzoyl sulphide, benzamide and benzoic ether. Berzelius recognized the importance of this work, although it overthrew his belief that oxygen could play no part in a compound radical. In the following year he reverted to his earlier views and his electro-chemical theory. He then regarded benzoyl as an oxide of the radical $C_{14}H_{10}(C_6H_5C)$, which he named *picramyl*, the peroxide being benzoic acid. Many workers were attracted to the task of investigating radicals, and of these, *formyl*, *methyl*, *amyl* and *acetyl* were soon established. In this connection should be mentioned the very important work of Robert Wilhelm Bunsen (1839) on *cacodyl*. He proved that the so-called *fuming liquor of Cadet*, the product of distillation of potassium acetate with arsenious acid, contained the oxide of an arseniuretted group, $As_2C_4H_{12}$, which he showed to be a true radical.

In 1837, Dumas admitted the failure of the etherin theory, and, in conjunction with Liebig, outlined what is now known as the *Older Theory of Radicals*, and defined organic chemistry as the chemistry of compound radicals. In the following year Liebig described a compound radical as the unchanging constituent of a series of compounds, which should be capable of replacement in these by simple substances, and, where it is combined with a single element, the latter should be exchangeable for its equivalent of another element. The radical was supposed to be constituted of atoms held together by forces stronger than those uniting the complete group to other atoms. These ideas attained a real significance for chemists, and, as the dualistic theory and the theory of compound radicals became more definitely useful, they rendered the atomic theory, on which they were founded, essential to chemistry.

Instances had already been recorded of the substitution of electro-positive atoms by electro-negative ones. Gay-Lussac obtained cyanogen chloride from hydrocyanic acid, and Faraday, hexachlorethane from ethylene dichloride, in both cases a replacement of hydrogen by chlorine. Dumas, especially, studied these substitutions, and from his examination of the action of chlorine on alcohol, put forward his *Substitution Theory*, in which he postulated that for every hydrogen atom eliminated, an equivalent amount of chlorine was taken up, without any material alteration in the nature of the resulting product. Dumas' pupil, Auguste Laurent (1836), went further, and compared in detail the original compounds with their substitution products. As a result, he propounded his *Nucleus Theory*, which differed from the original radical theory in that it recognized that the groups formerly termed radicals were subject to change, such as substitution by the interchange of equivalent amounts of their constituents. The discovery of chloracetic acid afforded Dumas the occasion for attacking the radical theory, and for supporting Laurent's view. There was vigorous opposition from Liebig and Berzelius, especially the latter, who resorted to fantastic hypotheses to explain the observed facts in order to suit his own theories. Finally he abandoned experiment for pure speculation, and there arose an embittered controversy which lasted for years.

Charles Frédéric Gerhardt also rejected the theory of unchangeable radicals and put forward his *Theory of Residues*, by which the substitution process consisted in the union of two residues to form a unitary whole. He considered radicals to be merely the residues of molecules which took no part in a particular chemical reaction, but which appeared as independent portions of those molecules, only when displaced in a reaction by combination be-

tween the reacting portions of molecules. Such residues then joined together to form a *copulated* or *conjugated* compound. He thus represented Liebig and Wöhler's reactions with the benzoyl compounds as double decompositions.

Theories of Chemical Types.—The radical theory, essentially dualistic, was destined to fall before a unitary conception. Dumas (1840) combined his theories of radicals and substitution with portions of Laurent's nucleus theory and Gerhardt's theory of residues into a comprehensive whole, now known as the *Older Theory of Types*. According to this a chemical type embraced compounds containing the same number of equivalents combined in a similar manner and exhibiting similar properties; thus acetic and trichloroacetic acids (CH_3COOH and CCl_3COOH), acetaldehyde and chloral (CH_3CHO and CCl_3CHO), marsh gas and chloroform (CH_4 and $CHCl_3$) are pairs of compounds referable to the same type. He also postulated, with Henri Victor Regnault, the existence of *molecular* or *mechanical types*, referring to substances which, although having the same number of equivalents, are essentially different in character; for example, alcohol and acetic acid (CH_3CH_2OH and CH_3COOH), in the second of which one atom of oxygen replaces two of hydrogen. This unitary conception may be summarized as follows: every chemical compound forms a complete whole and its chemical character depends primarily upon the number and arrangement of the atoms, and, in a lesser degree, upon their chemical nature.

Charles Adolphe Wurtz (1849) described the amines or substituted ammonias, previously predicted by Liebig. August Wilhelm von Hofmann continued the investigation, and established their recognition as ammonia in which one or more hydrogen atoms had been replaced by alcohol or hydrocarbon radicals, thus formulating the *ammonia type*. Alexander William Williamson (1850) demonstrated in a similar manner that the alcohols and ethers could be referred to the *water type*. In 1851, Adolph Wilhelm Hermann Kolbe put forward his *New Theory of Radicals*, but the main theoretical conclusions were better correlated by Gerhardt (1853) in his *Theory of Simple Types*, in which he regarded all compounds as derived from hydrogen, hydrogen chloride, water, and ammonia types. Thus the hydrogen type included the hydrocarbons, aldehydes and ketones, the hydrogen chloride type, all halogen derivatives, the water type, alcohols, ethers, monobasic acids, acid anhydrides and analogous sulphur compounds, and the ammonia type, amines, acid amides, and the analogous phosphorus and arsenic compounds. Gerhardt's services to chemistry can never be questioned.

The recognition of the polybasicity of some acids, following the researches of Thomas Graham, led Williamson to suggest that dibasic acids could be referred to a *double water type*, and the multi-basic acids to *multiple water types*. These views were extended by William Odling, and adopted by Gerhardt. A further generalization was effected by August Kekulé (1857), who rejected the hydrogen chloride type as being a variant only of the hydrogen type, and introduced instead the *methane type*. He elaborated Gerhardt's suggestion of *mixed types*, compounds derived from more than one fundamental type, and in so doing, laid the foundation of the doctrine of valency.

The Idea of Valency.—In 1852, Edward Frankland published his classical research on the organo-metallic compounds and represented them by formulae which brought out the analogy with the inorganic types. Frankland then developed the idea of *saturation capacities* of the various elements, the germ of which may be recognized much earlier in the law of multiple proportions. This law states, in effect, that the elements show different, yet definite stages in their combination. Frankland was able to predict the possibility of compounds then unknown, namely, the secondary and tertiary alcohols, and to show relationships between compounds previously held distinct, for example, lactic acid and alanine, glycollic acid and glycine, and salicylic and benzoic acids, were shown to be hydroxy- and amino-derivatives of propionic, acetic and benzoic acids respectively.

Kolbe and Frankland had recognized the quadrivalency of carbon, but this was first expressly stated by Kekulé (1858). Kekulé went further, and suggested the manner in which two or more of

these quadrivalent carbon atoms could unite with one another, mutually satisfying some of their saturation capacities. In the same year Archibald Scott Couper, quite independently, developed a similar system of atomic linkage. From this arose the idea of atomic carbon chains, either open, as in the fatty, or closed, as in the aromatic and cyclic series. This gave precision to the earlier observation of Jacob Heinrich Wilhelm Schiel (1842) that a very simple relation existed between the then known alcohols (general formula $C_nH_{2n+1}.OH$), and to Dumas' demonstration in the same year of the existence of a similar relation between the several members of the fatty acids ($C_nH_{2n+1}.COOH$). Gerhardt (1844) was the first to use this knowledge of related series of chemical compounds to predict the possibility of hitherto unknown members. These series of compounds, called *homologous series*, are now known to possess the same characteristic groups at the ends of carbon chains of variable length. Thus the first members of the simple fatty acid series are: acetic acid, $CH_3.COOH$; propionic acid, $CH_3(CH_2).COOH$; butyric acid, $CH_3(CH_2)_2.COOH$, etc.

The doctrine of valency permitted the graphic representation of the molecule. These representations were at first written in one plane only, but a number of cases were then discovered which did not appear to be capable of explanation by such *structural formulae*. Ludwig Carius (1864) suggested the term *physical isomerism* to describe these anomalies, but Johannes Wislicenus (1873) introduced the term *geometrical isomerism* and showed that it was possible to account for the phenomenon if such molecules were represented in three dimensions. This *Structure Theory* of the carbon compounds, founded by Kekulé and Couper, was further developed by the work of Jacobus Henricus Van't Hoff and Joseph Achille Le Bel on *stereochemistry* or chemistry in space. By its aid the molecule is represented as a collection of atoms connected together by chemical *bonds* or valencies in such a manner that the part played by each is adequately represented. After 1870 the determination of the constitution of complex molecules became one of the chief aims of chemistry, to be brought to a logical conclusion by subsequent synthesis.

ALIPHATIC DIVISION

In this section are outlined the classification, general methods of preparation, and characteristics of the very large number of substances concerned. There are special articles on most of the technically valuable members of this subdivision and on important theoretical considerations such as valency, isomerism and stereochemistry.

Hydrocarbons.—The compounds of carbon and hydrogen known as hydrocarbons occur naturally as petroleum, mineral oil, and ozokerite, or are formed by the distillation of coal, brown coal or shale. The chemical characteristics of those individual hydrocarbons isolated from such sources are so well defined that it is possible to classify them into three groups: aliphatic, homo-cyclic and heterocyclic, this section dealing with the first group. This group, of which marsh gas found in the coal measures is the simplest representative, is further subdivided by the chemical properties of its members into four main classes: (i.) paraffins, (ii.) olefines or ethylenes, (iii.) acetylenes and (iv.) di-olefines. The number of these hydrocarbons, and more particularly of their derivatives, is so large that it will only be possible to consider a few simple members in each important class; but since the members of any one series closely resemble one another, a description of the simpler gives a general knowledge of the more complicated.

(i.) *Paraffins*. Analysis and molecular-weight determination of the simplest possible hydrocarbon, marsh gas or methane, lead to the formula CH_4 . Organic chemistry has been built up on the

conception that carbon is quadrivalent; *i.e.*, that this element is capable of combining with four atoms of hydrogen to form a stable compound. Further, it has been shown experimentally that the four hydrogen atoms are of equal value, and consequently the only method of picturing the arrangements of the atoms in this molecule is to regard the carbon as situated in the centre of a sphere, with its four valencies directed symmetrically in space. This view of the molecular architecture of marsh gas will be referred to later; in the meanwhile, the graphic formula will be written as

When chlorine acts on marsh gas, the first substance formed is methyl chloride, a sweet-smelling gas boiling at -24°C ; one hydrogen atom in the original substance has been replaced by chlorine with the simultaneous formation of hydrogen chloride. The further action of chlorine replaces a second and so on, until finally tetrachloromethane or carbon tetrachloride, CCl_4 (b.p. 76°C), results; this is a valuable commercial solvent (*see CARBON*). This behaviour of marsh gas with chlorine is typical of the whole group of the paraffins, and it is for this reason that they are termed *saturated*, and are alluded to as the *limit hydrocarbons*.

Methyl iodide, corresponding closely to the chloride, is a liquid boiling at 43°C . If dissolved in an inert solvent and treated with metallic sodium, it forms sodium iodide, and the two methyl groups join together forming ethane, CH_3-CH_3 , the next member of the series. It is possible similarly to synthesize propane, $CH_3-CH_2-CH_3$, boiling at -44°C , butane, $CH_3-CH_2-CH_2-CH_3$, boiling at 1°C , and so on, with a complete knowledge of the molecular structure of these substances. Hydrocarbons of this type, the molecules of which consist of carbon linked to carbon in unbranched chains, are known as *normal* (written as *n*-), and the term *homologous* is applied to such a series in which each member differs by $-CH_2$ from the next. The general physical properties of homologous series vary in much the same way; the lower members are gases and as they become more complex, they pass to liquids of low, then high, boiling points, and finally to solids of low, then high, melting points.

Paraffins of this type occur in various petroleum. Ethane, a gas, is found dissolved in the oils from certain wells, such as those of Pittsburgh. Pentane, boiling at 36°C , hexane at 69°C , and heptane at 93°C , etc., have been isolated from Pennsylvanian oils. Similar oils also contain in varying amounts the solid members of this series known as *paraffin wax*, a mixture of *n*-hydrocarbons, which is also manufactured by the distillation of shale or brown coal. Waxes of Scottish origin, and probably all such materials, are composed of about 10 to 12 normal hydrocarbons of which the most important are: docosane $C_{22}H_{46}$, tetracosane $C_{24}H_{50}$, pentacosane $C_{25}H_{52}$, hexacosane $C_{26}H_{54}$, octacosane $C_{28}H_{58}$, nonacosane $C_{29}H_{60}$, and hentriacontane $C_{31}H_{64}$. Many of these solid hydrocarbons have also been isolated from the animal or plant world, the most complex being hexacontane $C_{60}H_{122}$, melting at 102°C .

There are two hydrocarbons known of the formula C_4H_{10} : one, *n*-butane, has been mentioned above; the other boils at -17°C , and has exactly the same percentage composition and vapour density and hence molecular weight. This phenomenon, termed *isomerism* (*q.v.*), receives a most satisfactory explanation on the conception of valency previously mentioned. With four carbon and ten hydrogen atoms, it is possible to form two and only two different structures, viz.,

Hydrocarbons containing such a branched chain are designated by the prefix *iso*; hence, in this case, as but two isomerides exist, the names *n*-butane and isobutane are sufficient to identify these substances.

Another example of isomerism is seen in the existence of three different hydrocarbons for the formula C_5H_{12} . The first, *n*-pentane, has been mentioned; the second boils at 30° C, and the third at 9° C. As it is only possible to arrange five quadrivalent carbon atoms and 12 hydrogen atoms in three ways, these hydrocarbons must be

As the hydrocarbons become more complex, the number of theoretically possible isomerides increases very rapidly indeed; in fact, it can be calculated that the hydrocarbon tridecane, $C_{13}H_{28}$, could exist in 802 different forms. The *normal* hydrocarbon, however, is the only one known. After the seventh member of the series, the number of known isomerides is very considerably less than those theoretically possible, and after the eleventh, with but few exceptions, the *normal* isomerides only have been examined.

The whole of this group of hydrocarbons is characterized by great inertness towards chemical reagents, thus differing very markedly from the benzene series. With chlorine (or bromine), however, they give substitution products, some of which are of industrial value. Partial oxidation (when this operation is effected without breaking down the hydrocarbon to carbon dioxide and water—the ultimate oxidation products of all organic substances) leads to valuable derivatives. Both formaldehyde (*q.v.*) and methyl alcohol (*q.v.*) can be prepared by the partial oxidation of marsh gas, and since this hydrocarbon can be obtained by the reduction of either carbon monoxide or dioxide, the possibility of preparing organic substances such as acetic acid and acetone from coal or even from limestone becomes realizable (*see METHYL ALCOHOL*).

(ii.) *Olefines*. When ethyl iodide, C_2H_5I , is heated with alcoholic soda, a gas called ethylene (or olefine) is evolved which, on analysis and density determination, is found to have the molecular formula C_2H_4 . The same substance can be formed by the dehydration of ethyl alcohol. These reactions may be depicted thus: $\text{CH}_3\text{—CH}_2\text{I—HI}=\text{CH}_2\text{—CH}_2$ and $\text{CH}_3\text{—CH}_2\text{OH—H}_2\text{O}=\text{CH}_2\text{—CH}_2$. In ethylene and all its homologues two adjoining carbon atoms appear each to be trivalent. Ethylene and its homologues show a set of reactions which differentiate them sharply from the paraffins; they readily absorb hydrogen, becoming paraffins, and combine with chlorine or bromine to yield oily di-substitution products of saturated hydrocarbons. It is to the formation of its oily dichloride that ethylene owes its historic name of olefine or olefant (oil-forming) gas (1795). Owing to these and similar “additive” reactions, the olefines are termed *unsaturated*, and the conventional method of indicating such characteristics is to regard the carbon atoms as linked together by two valencies: *e.g.*, $\text{CH}_2=\text{CH}_2$. This arrangement retains the conception of the quadrivalency of carbon, but it is not intended to indicate that the carbon atoms are more tightly held together than they are in the case of ethane $\text{CH}_3\text{—CH}_3$ with a single linkage between each other.

Some of the reactions of ethylene may be summarized:—(i.) $\text{CH}_2=\text{CH}_2 + \text{H}_2 = \text{CH}_3\text{—CH}_3$; (ii.) $\text{CH}_2=\text{CH}_2 + \text{Br}_2$ (or Cl_2) $= \text{CH}_2\text{Br—CH}_2\text{Br}$, ethylene dibromide (or $\text{CH}_2\text{Cl—CH}_2\text{Cl}$, ethylene dichloride); (iii.) $\text{CH}_2=\text{CH}_2 + \text{HI} = \text{CH}_3\text{—CH}_2\text{I}$, ethyl iodide; (iv.) $\text{CH}_2=\text{CH}_2 + \text{H}_2\text{SO}_4 = \text{C}_2\text{H}_5\text{HSO}_4$, ethyl hydrogen sulphate; (v.) mild oxidation converts ethylene into glycol, $\text{CH}_2\text{OH—CH}_2\text{OH}$. Generally these reactions are manifested by all organic substances containing the double linkage. In the homologous series of olefines, the phenomenon of isomerism is first noticed in the case of butylene, C_4H_8 , which occurs in the three theoretically possible forms:—

(iii.) *Acetylenes*. When ethylene dibromide is treated with alcoholic potash or soda, acetylene is formed: $\text{CH}_2\text{Br—CH}_2\text{Br} - 2\text{HBr} = \text{CH—CH}$. In this hydrocarbon, and its homologues,

carbon appears to be bivalent, and for reasons similar to those just ascribed in the case of ethylene, a *triple linkage* is written between the carbon atoms; *e.g.*, $\text{CH}\equiv\text{CH}$. This gas, which is much more easily and inexpensively prepared by the action of water on calcium carbide (*see CARBIDES*), readily takes up hydrogen, giving ethylene. The homologous hydrocarbons of this series readily undergo a change known as *polymerization* (*q.v.*); thus acetylene passed through a red-hot tube gives benzene: $3\text{C}_2\text{H}_2 = \text{C}_6\text{H}_6$. The hydrogen atoms in acetylene can be replaced by metals, and the explosive red copper and white silver compounds are used for the characterization of this substance. Under the catalytic influence of mercuric salts, acetylene combines with water giving acetaldehyde (*see ALDEHYDES*), a substance which may be readily oxidized to acetic acid (*q.v.*), or reduced to ethyl alcohol.

(iv.) *Di-Olefines*. These hydrocarbons are isomeric with the homologues of acetylene, butadiene, $\text{CH}_2=\text{CH—CH=CH}_2$, being isomeric with ethylacetylene, $\text{CH}_3\text{—CH}_2\text{—C}\equiv\text{CH}$. Unlike the acetylenes, they do not form copper or silver salts. The most interesting members of this series are those which undergo polymerization to a substance resembling caoutchouc. This is the case with butadiene and with isoprene, $\text{CH}_2=\text{C}(\text{CH}_3)\text{—CH=CH}_2$. The latter hydrocarbon, warmed for 50 hours at 60° C with sodium in a sealed tube, gives a nearly quantitative yield of a substance with properties very similar to those of rubber.

Oxidation Products of Hydrocarbons.—The paraffins are oxidized only with difficulty; consequently other sources of their valuable oxidation products have to be found. It has already been mentioned that methane and methyl alcohol can be obtained by the reduction of carbon monoxide or dioxide, and that acetic acid and acetone can be prepared indirectly from coal. Methyl alcohol (methanol), CH_3O , acetic acid, $\text{C}_2\text{H}_4\text{O}_2$, and acetone, $\text{C}_3\text{H}_6\text{O}$, also arise from the distillation of wood. Ethyl alcohol, $\text{C}_2\text{H}_5\text{O}$, is manufactured in enormous quantity by vinous fermentation, and butyl alcohol is the most important product of the bacterial fermentation of maize. Such oxidized products of the hydrocarbons, and not the inert hydrocarbons themselves, are the starting materials for a large number of aliphatic syntheses.

The Alcohols. Methyl alcohol, CH_3O , when acted upon by metallic sodium, evolves hydrogen and gives sodium methoxide, CH_3ONa . This and other reactions show that one hydrogen atom is different from the other three, indicated graphically by linking that hydrogen to oxygen, forming the *hydroxyl group* (OH), thus methyl alcohol is CH_3OH , ethyl alcohol $\text{CH}_3\text{CH}_2\text{OH}$, and so on. It has been observed that when once oxygen has entered into such stable substances as the paraffins, further oxidation is easy. Ethyl alcohol, for example, is readily oxidized to acetaldehyde:

Substances containing two hydroxyl groups attached to one carbon atom are very unstable and at once lose water giving the aldehyde. It will be noticed that oxygen has attacked the carbon atom which is already partly oxidized. This is invariably the case provided that such a carbon atom has hydrogen attached to it.

In the hydrocarbon propane, $\text{CH}_3\text{—CH}_2\text{—CH}_3$, the *terminal* hydrogen atoms are symmetrically situated in the molecule, hence theoretically but one *n*-propyl alcohol, $\text{CH}_3\text{—CH}_2\text{—CH}_2\text{OH}$, is capable of existence, and one only is actually known. This alcohol behaves on oxidation in a similar manner to ethyl alcohol, giving first propyl aldehyde, $\text{CH}_3\text{CH}_2\text{CHO}$, and then propionic acid, $\text{CH}_3\text{CH}_2\text{COOH}$.

When the two central hydrogen atoms in propane are considered, it will be seen that a second isomeric alcohol, $\text{CH}_3\text{CH}(\text{OH})\text{CH}_3$, is possible, and actually, two isomerides are invariably found when a hydrogen atom in propane is replaced by univalent groups or such elements as chlorine, bromine, etc. Isopropyl alcohol, $\text{CH}_3\text{CH}(\text{OH})\text{CH}_3$, is oxidized to acetone, a typical member of the group of *ketones* (*q.v.*):—

The Aldehydes. When acted upon by phosphorus pentachloride, the oxygen of the aldehydes is replaced by two atoms of chlorine; thus, acetaldehyde, CH_3CHO , gives ethylidene chloride,

CH_3CHCl_2 , isomeric with ethylene dichloride, $\text{CH}_2\text{Cl}\cdot\text{CH}_2\text{Cl}$. When aldehydes are further oxidized, they pass to acids as follows:—

the third substance, for reasons already mentioned, being unstable and losing a molecule of water.

The Organic Acids. $\text{R}\cdot\text{CO}_2\text{H}$ (see ACIDS), all contain the carboxyl group $-\text{COOH}$. If acetic acid, $\text{C}_2\text{H}_4\text{O}_2$, is acted upon by phosphorus pentachloride, acetyl chloride, $\text{C}_2\text{H}_3\text{OCl}$, results, a proof that the acid contained the OH group. The chlorine atom in this substance can be replaced by NH_2 by acting upon it with ammonia, and the resulting substance, $\text{C}_2\text{H}_5\text{ONH}_2$, can be dehydrated, giving acetonitrile, $\text{C}_2\text{H}_3\text{N}$, which can also be synthesized from methyl iodide and potassium cyanide, $\text{CH}_3\text{I}+\text{KCN}=\text{KI}+\text{CH}_3\text{CN}$. These observations, which show that acetic acid contains a methyl group (CH_3) linked to carbon, and in addition, a hydroxyl group, support the foregoing formula for acetic acid.

The alcohols, ketones, aldehydes and acids constitute the most important oxygen-containing materials of organic chemistry. Derivatives are known containing two or more of the same characteristic groups; e.g., glycerine, $\text{CH}_2(\text{OH})\cdot\text{CH}(\text{OH})\cdot\text{CH}_2(\text{OH})$, or malonic acid, $\text{CH}_2(\text{COOH})_2$, and, on the other hand, organic substances have been synthesized, or occur naturally, containing two or more different groups such as lactic acid, $\text{CH}_3\text{CH}(\text{OH})\cdot\text{COOH}$ (*q.v.*) or one of the tartaric acids, $\text{COOH}\cdot\text{CH}(\text{OH})\cdot\text{CH}(\text{OH})\cdot\text{COOH}$ (*q.v.*).

Alcohols.—These substances are classified in accordance with the nature of the hydrocarbon in which hydrogen has been replaced by (OH). If such an atom be replaced in the paraffins, the *saturated alcohols* result, several of which have been previously discussed. When the replacement occurs in one of the ethylene hydrocarbons, an *unsaturated alcohol* such as allyl alcohol, $\text{CH}_2=\text{CH}\cdot\text{CH}_2\text{OH}$, is formed. An alcohol of this type, besides showing the characteristics of alcohols, has, in addition, the properties of unsaturated hydrocarbons. Allyl alcohol on oxidation gives acrolein, $\text{CH}_2=\text{CH}\cdot\text{CHO}$, which in turn gives acrylic acid, $\text{CH}_2=\text{CH}\cdot\text{COOH}$, and on reduction passes to *n*-propyl alcohol, $\text{CH}_3\text{CH}_2\cdot\text{CH}_2\text{OH}$.

Those alcohols containing the group $-\text{CH}_2\text{OH}$, which pass on oxidation into aldehydes and acids of the same carbon content, are known as *primary* alcohols. Those containing the $\text{CH}\cdot\text{OH}$ group, termed *secondary* alcohols, on oxidation give ketones having the same number of carbon atoms. A third class called *tertiary* alcohols, for instance, tertiary butyl alcohol, $(\text{CH}_3)_3\text{C}\cdot\text{OH}$, give, when oxidized, substances of smaller carbon content.

Alcohols can be synthesized from the corresponding halogen derivative by the action of hydrated silver oxide or lead oxide and water; thus ethyl iodide, $\text{C}_2\text{H}_5\text{I}$, gives ethyl alcohol. Such a reaction as this may be used for introducing several OH groups. Ethylene dibromide, treated in a similar manner, gives glycol, $\text{CH}_2(\text{OH})\cdot\text{CH}_2\text{OH}$. Alcohols also result from the reduction of ketones and aldehydes. Ethylene dissolves in strong sulphuric acid to give ethyl hydrogen sulphate, $\text{C}_2\text{H}_5\text{HSO}_4$; when this is treated with warm water, it generates sulphuric acid and gives ethyl alcohol, which may be separated by distillation. Propylene, $\text{CH}_2=\text{CH}\cdot\text{CH}_3$, dissolves in the concentrated acid to give isopropyl hydrogen sulphate, $(\text{CH}_3)_2\text{CH}\cdot\text{HSO}_4$, which passes to isopropyl alcohol, $(\text{CH}_3)_2\text{CH}\cdot\text{OH}$, on treatment with water. Since propylene is formed by dehydrating *n*-propyl alcohol, this process effects the conversion of a primary into a secondary alcohol. The properties of the more important alcohols are described under ALCOHOLS.

The lower members of the paraffin alcohols are miscible with water in all proportions, but as the series is ascended, the solubility diminishes rapidly. Both methyl and ethyl alcohols are extremely valuable solvents for organic substances.

With sulphuric acid, alcohols give hydrogen sulphates:

$\text{CH}_3\text{OH}+\text{H}_2\text{SO}_4=\text{CH}_3\text{HSO}_4+\text{H}_2\text{O}$. If this acid sulphate be distilled, dimethyl sulphate is formed $(\text{CH}_3)_2\text{SO}_4$, a substance largely used in industry for the introduction of the methyl (CH_3) group. The corresponding organic analogues are prepared by heating together alcohol and an organic acid, and are called *esters*. From acetic acid and ethyl alcohol, for instance, ethyl acetate $\text{CH}_3\cdot\text{COOC}_2\text{H}_5$, is formed.

Ethers.—The group of ethers is closely related to the alcohols, and ordinary ether (*q.v.*) may be taken as a typical representative. This substance may be regarded as ethyl alcohol in which the hydrogen of the hydroxyl group has been replaced by another ethyl group, $\text{C}_2\text{H}_5\cdot\text{O}\cdot\text{C}_2\text{H}_5$. When sodium acts on ethyl alcohol, the resulting derivative is sodium ethoxide, $\text{C}_2\text{H}_5\text{ONa}$, and when this is treated with ethyl iodide, the following reaction takes place: $\text{C}_2\text{H}_5\text{ONa}+\text{IC}_2\text{H}_5=\text{NaI}+\text{C}_2\text{H}_5\cdot\text{O}\cdot\text{C}_2\text{H}_5$. This synthesis, which is of general applicability, leads directly to the constitutional formula of the resulting ether. The usual method for the preparation of this valuable anaesthetic consists in the interaction of ethyl alcohol and ethyl hydrogen sulphate: $\text{C}_2\text{H}_5\text{HSO}_4+\text{C}_2\text{H}_5\text{OH}=(\text{C}_2\text{H}_5)_2\text{O}+\text{H}_2\text{SO}_4$.

Ethers, which are isomeric with alcohols, are neutral substances only slightly soluble in water, and ethyl ether is largely used as a solvent in organic chemistry. The simplest, methyl ether, $\text{CH}_3\cdot\text{O}\cdot\text{CH}_3$, isomeric with ethyl alcohol, $\text{C}_2\text{H}_5\text{OH}$, is a gas only slightly soluble in water and unacted upon by sodium, whereas ethyl alcohol is miscible in all proportions with water and evolves hydrogen when acted upon by an alkali metal.

Aldehydes and Ketones.—Both in their mode of formation and in their properties the ketones show great resemblance to the aldehydes (see above), the two series resulting from the oxidation of the secondary and primary alcohols respectively, and both can be obtained by the distillation of suitable calcium salts of the acids or mixtures of these.

The simplest ketone, acetone, $\text{CH}_3\cdot\text{CO}\cdot\text{CH}_3$ (*q.v.*), is one of the products of the bacterial fermentation of maize, and is made technically by the distillation of calcium acetate $(\text{CH}_3\text{COO})_2\text{Ca}=\text{CaCO}_3+\text{CH}_3\cdot\text{CO}\cdot\text{CH}_3$. Ketones neither oxidize as readily as aldehydes, nor polymerize; otherwise their reactions are strikingly similar. Like the aldehydes, the ketones combine with sodium bisulphite and hydrocyanic acid; both aldehydes and ketones condense with hydroxylamine to form "aldoximes," $\text{R}\cdot\text{CH}\cdot\text{N}\cdot\text{OH}$, and "ketoximes," $\text{RR}'\text{C}\cdot\text{N}\cdot\text{OH}$, respectively.

Acids.—Organic acids containing the carboxyl group, $\cdot\text{COOH}$, are classifiable according to the nature of the hydrocarbon the hydrogen atom of which is replaced by this group. If replacement occurs in the paraffins, the saturated acids result. Thus, methane gives acetic acid, $\text{CH}_3\cdot\text{COOH}$. If a hydrogen atom in the ethylene hydrocarbons is replaced, the unsaturated acids appear; thus $\text{CH}_2=\text{CH}_2$ gives acrylic acid, $\text{CH}_2=\text{CH}\cdot\text{COOH}$. The possibilities of isomerism in the saturated acids are very similar to those previously discussed. Thus, there are two isomerides containing four carbon atoms, namely, *n*-butyric acid, $\text{CH}_3\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{COOH}$, and isobutyric acid, $\text{CH}_3\cdot\text{CH}(\text{COOH})\cdot\text{CH}_3$ (see ACIDS). The substances under discussion are termed fatty acids, since the higher members, combined with glycerine as esters, form the group of natural fats or glycerides (*q.v.*), which on boiling with alkalis give glycerine and the alkali salts of such saturated acids as stearic and palmitic acids, together with the unsaturated oleic acid. This breakdown of an organic ester is termed *saponification*, although the term is now used in the somewhat broader sense of hydrolysis (a loosening by water).

A valuable synthetic method for the preparation of acids consists in the formation of *nitriles* by the interaction of an alkyl iodide such as ethyl iodide with potassium cyanide, $\text{C}_2\text{H}_5\text{I}+\text{KCN}=\text{C}_2\text{H}_5\text{CN}+\text{KI}$, and the subsequent saponification or hydrolysis of nitriles with aqueous alkali, the alkali salt of the acid being formed: $\text{C}_2\text{H}_5\cdot\text{CN}+\text{KOH}+\text{H}_2\text{O}=\text{C}_2\text{H}_5\cdot\text{COOK}+\text{NH}_3$.

The reactions of the acids are described under that heading, and the acid-amides derived therefrom by replacement of a hydroxyl group by an amino-group are also described separately. The action of phosphorus pentachloride upon acids gives the *acid chloride*, e.g., $\text{CH}_3\cdot\text{COOH}+\text{PCl}_5=\text{CH}_3\cdot\text{COCl}+\text{POCl}_3+\text{HCl}$, and

these react with the alkali salts of the acids to give anhydrides: $\text{CH}_3\text{-COCl} + \text{CH}_3\text{-COONa} = (\text{CH}_3\text{CO})_2\text{O} + \text{NaCl}$.

The anhydrides react with water, alcohol or ammonia to give the acid, ester or amide respectively:—

Palmitic, stearic and oleic acids are of great commercial importance and are dealt with in the article FATTY ACIDS. The structures of the first two are known from application of methods already indicated to be respectively $\text{C}_{15}\text{H}_{31}\text{COOH}$ and $\text{C}_{17}\text{H}_{33}\text{COOH}$, all the carbon atoms being in a straight chain. Since oleic acid is $\text{C}_{17}\text{H}_{33}\text{CO}_2\text{H}$, it is of importance to determine the actual position of the double linkage, and this has been shown by the investigation of the ozone addition product. Such compounds result from the interaction of the two doubly linked carbon atoms with this reagent, and when decomposed break down at this point. The oleic acid derivative yields an aldehyde $\text{CH}_3(\text{CH}_2)_7\text{CHO}$ and an aldehyde-acid $\text{CHO}\cdot(\text{CH}_2)_7\text{COOH}$. Consequently the double linkage lies in the centre of the $\text{CH}_3\cdot[\text{CH}_2]_7\cdot\text{CH}:\text{CH}\cdot[\text{CH}_2]_7\cdot\text{COOH}$ molecule.

Dicarboxylic Acids.—These acids contain two carboxyl groups. Glycol, $\text{CH}_2(\text{OH})\cdot\text{CH}_2\text{OH}$, on oxidation gives oxalic acid, $\text{COOH}\cdot\text{COOH}$. Ethylene dibromide gives ethylene dicyanide, or succinonitrile, $\text{CH}_2\text{CN}\cdot\text{CH}_2\text{CN}$, when acted upon by aqueous potassium cyanide; this nitrile when saponified gives succinic acid, $\text{CO}_2\text{H}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$.

The properties of these acids depend on the relative position in the molecule of the two carboxyl groups. Malonic acid, $\text{CH}_2(\text{COOH})_2$, when heated evolves carbon dioxide and forms acetic acid, whereas succinic acid gives an anhydride $(\text{CH}_2\text{CO})_2\text{O}$.

If succinic acid is chlorinated, the first product is chlorosuccinic acid, $\text{CO}_2\text{H}\cdot\text{CH}_2\cdot\text{CHCl}\cdot\text{CO}_2\text{H}$. When this is acted upon by alcoholic alkalis, fumaric acid is formed, $\text{COOH}\cdot\text{CH}=\text{CH}\cdot\text{COOH}$. This unsaturated acid shows the properties both of ethylene and of succinic acid. It sublimes at 200°C , and at a higher temperature gives an anhydride which on warming with water, does not revert to fumaric acid, but gives an isomeride, maleic acid, which melts at 130°C , and reverts to fumaric acid when its aqueous solution is heated to about 200°C . Both of these acids have the same structural formula, viz., $\text{COOH}\cdot\text{CH}=\text{CH}\cdot\text{COOH}$, and consequently this is the first case considered where the uniplanar conception of valency fails to account for the existence of a pair of isomerides. An extension of the conception used hitherto is therefore necessary, and this is made along the lines of STEREO-CHEMISTRY (*q.v.*). Briefly, the explanation of this type of isomerism (or stereoisomerism) is to be found in the different relative positions in space of the groups attached to the carbon atoms, thus:—

The decision as to which formula should be ascribed to the individual acids may be determined by their chemical reactivity. Thus, maleic acid very readily loses water and passes into maleic anhydride, and for this reason the two carboxyl groups are supposed to be near together in space. By this and similar arguments, it is possible to determine the configuration of such pairs of isomerides.

Substances Containing Two or More of the Functional Groups.—Alcohols containing one or more hydroxyl groups have been mentioned. Similarly aldehydes, ketones and acids have been discussed, and in addition a few dicarboxylic acids and their derivatives have been alluded to in order to bring out points of theoretical importance. A knowledge of the characteristics of these functional groups in these four classes, and of the alteration in the properties of the hydrocarbons when such groups are sub-

stituted for hydrogen atoms, affords very valuable evidence for the determination of the structure of new organic substances discovered in the animal or plant world. Large and important groups of aliphatic derivatives have been synthesized containing two or more different functional groups, and of these a few selections will now be discussed.

Hydroxy-Aldehydes and -Ketones.—The hexahydric alcohols such as mannitol or mannite, $\text{CH}_2\text{OH}\cdot(\text{CHOH})_4\cdot\text{CH}_2\text{OH}$, are soluble in water and have a sweet taste, but unlike the sugars they do not reduce alkaline copper solutions, are not fermented by yeast, and cannot be utilized as a food by the body. When a (CH_2OH) group is oxidized to the CHO group, or an adjacent (CHOH) group is converted into a CO group, the sugars result. These important compounds are also termed *carbohydrates* and are described more fully under that heading. Grape-sugar (*d*-glucose), $\text{CH}_2\text{OH}\cdot(\text{CHOH})_4\cdot\text{CHO}$, occurs in many fruits and in honey, and in most sweet fruits laevulose (fruit-sugar or *d*-fructose), $\text{CH}_2\text{OH}\cdot[\text{CHOH}]_3\cdot\text{CO}\cdot\text{CH}_2\text{OH}$, is found.

Owing to the different arrangements of the valencies of the carbon atoms in space, numerous other compounds are capable of existence having the same *plane* formulae; thus there are 16 possible stereoisomerides all having the same structure as glucose, and 14 of these are known. The carbohydrates are divided for convenience into four main groups according to the number of carbon atoms in space, numerous other compounds are capable of hydrogen atoms to oxygen atoms is 2:1, as in water—hence the name *carbohydrate*.

The monosaccharides are grouped about the *hexoses*, $\text{C}_6\text{H}_{12}\text{O}_6$, of which glucose and fructose (*see above*) are the most important; *pentoses*, $\text{C}_5\text{H}_{10}\text{O}_5$, are included in this group. The *disaccharides*, $\text{C}_{12}\text{H}_{22}\text{O}_{11}$, may be regarded as derived by the loss of water from two similar or dissimilar monosaccharide molecules: $2\text{C}_6\text{H}_{12}\text{O}_6 - \text{H}_2\text{O} = \text{C}_{12}\text{H}_{22}\text{O}_{11}$. Cane-sugar (sucrose or saccharose) is the most important member of this group, which also includes lactose (or milk-sugar) and maltose (or malt-sugar); on hydrolysis it yields equal parts of glucose and fructose, whereas maltose gives only glucose. The *trisaccharides*, $\text{C}_{18}\text{H}_{32}\text{O}_{16}$ ($= 3\text{C}_6\text{H}_{12}\text{O}_6 - 2\text{H}_2\text{O}$) are rare, but the *polysaccharides* ($\text{C}_n\text{H}_{10n}\text{O}_5$) where *n* is generally a large number, are very well known in the form of starch and cellulose.

Hydroxy-Acids.—When acetic acid is chlorinated, the first product is monochloroacetic acid, $\text{CH}_2\text{Cl}\cdot\text{COOH}$, which, on boiling with water, yields hydroxy-acetic or glycollic acid, $\text{CH}_2\text{OH}\cdot\text{COOH}$, also found in unripe grapes. One of the most characteristic reactions of aldehydes is the formation of cyanohydrins with hydrocyanic acid. Thus, acetaldehyde readily gives acetaldehyde cyanohydrin, $\text{CH}_3\cdot\text{CH}(\text{OH})\cdot\text{CN}$. When this is saponified, *inactive* lactic acid, $\text{CH}_3\cdot\text{CH}(\text{OH})\cdot\text{COOH}$, is formed. Lactic acid, which contains an asymmetric carbon atom (*see STEREOCHEMISTRY*), occurs in three forms; the optically inert isomeride is formed during the lactic acid fermentation of carbohydrates such as lactose and glucose, and is consequently present in sour milk. Sarcocollactic acid, the dextrorotary modification, occurs in meat juice, and the laevoform may be prepared by resolution of the ordinary inert acid. Isomeric with lactic acid is β -hydroxy-propionic acid $\text{CH}_2(\text{OH})\cdot\text{CH}_2\cdot\text{COOH}$, which may be taken as an illustration of the nomenclature employed in this group of acids. The next higher is termed γ -hydroxybutyric acid ($\text{CH}_2\text{OH}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{COOH}$).

On heating these hydroxy-carboxylic acids, it is found that their behaviour depends on the relative position of the two functional groups. Lactic acid, where both are linked to the same carbon atom, loses two molecules of water from two of the acid and gives lactide. β -hydroxy-propionic acid loses water and gives the unsaturated acrylic acid, $\text{CH}_2=\text{CH}\cdot\text{COOH}$. But the most interesting anhydride formation takes place with the next homologues—the γ - and δ -hydroxy-acids—which give rise to stable γ - and δ -lactones, containing 5- and 6-membered rings:—

Citric acid, $\text{CH}_2(\text{COOH})\cdot\text{C}(\text{OH})(\text{COOH})\cdot\text{CH}_2\text{COOH}$, widely disseminated in many varieties of fruit—lemons, currants, gooseberries, etc.—is manufactured from lemon juice which contains 6–7%, and also by a fermentation process (*Citromyces*) from carbohydrates, glycerine and similar substances. It has been synthesized from dichloroacetone, $\text{CH}_2\text{Cl}\cdot\text{CO}\cdot\text{CH}_2\text{Cl}$, which absorbs hydrocyanic acid, giving $\text{CH}_2\text{Cl}\cdot\text{C}(\text{OH})(\text{CN})\cdot\text{CH}_2\text{Cl}$, a cyanohydrin, saponifiable to the dichlorohydroxy-acid. The chlorine atoms are then replaced by cyanogen (CN) groups through the agency of potassium cyanide, and saponification of the resulting dinitrile leads to citric acid.

Ketonic Acids.—The most interesting member of this group is acetoacetic acid, best known as $\text{CH}_3\cdot\text{CO}\cdot\text{CH}_2\cdot\text{COOC}_2\text{H}_5$, ethyl acetoacetate, which, owing to its peculiar properties, and great chemical reactivity, has been more fully investigated than any other aliphatic derivative, and is therefore described separately. Its behaviour is often in accord not only with the above formula, but also with the constitution $\text{CH}_3\cdot\text{C}(\text{OH})\cdot\text{CH}\cdot\text{COOC}_2\text{H}_5$. A substance such as this, the constitution of which appears to vary according to conditions, giving rise to two types of derivatives, is an example of the phenomenon of *tautomerism* (*q.v.*).

Acetoacetic ester, when treated with sodium, or with alcoholic sodium ethoxide, gives a highly reactive sodium derivative which, when acted upon by ethyl iodide, yields ethyl ethylacetoacetate, $\text{CH}_3\cdot\text{CO}\cdot\text{CH}(\text{C}_2\text{H}_5)\cdot\text{COOC}_2\text{H}_5$. A repetition of these processes gives ethyl diethylacetoacetate, $\text{CH}_3\cdot\text{CO}\cdot\text{C}(\text{C}_2\text{H}_5)_2\cdot\text{COOC}_2\text{H}_5$. Acetoacetic ester itself or its mono- or di-ethyl derivative can be decomposed by alkalis or acids in suitable concentrations to give a preponderating yield of either ketones or acids. The mono-ethyl derivative can give either a ketone, $\text{CH}_3\cdot\text{CO}\cdot\text{CH}_2(\text{C}_2\text{H}_5)$, or an acid, $\text{CH}_2(\text{C}_2\text{H}_5)\cdot\text{COOH}$, and when it is remembered that a variety of groups can be introduced into the original ester, it will be realized that a large number of derivatives can be synthesized, of acetone on the one hand, and acetic acid on the other.

Moreover, the sodium derivatives of acetoacetic ester and of its mono-alkyl homologues, when acted upon by alcoholic iodine, furnish a condensation product,

with elimination of sodium as sodium iodide. The new derivative can then be decomposed to give either di-ketones,

or dicarboxylic acids, $\text{CO}_2\text{H}\cdot\text{CHR}\cdot\text{CHR}\cdot\text{CO}_2\text{H}$, where R is a hydrogen atom or an alkyl group.

Malonic ester, $\text{CH}_2(\text{COOC}_2\text{H}_5)_2$, is another very reactive ester of considerable utility in syntheses. Thus, with either sodium or sodium ethoxide, it gives a reactive sodium derivative which readily decomposes with ethyl iodide to give ethylmalonic ester, $\text{CH}(\text{C}_2\text{H}_5)(\text{COOC}_2\text{H}_5)_2$. The acids derived from any of these malonoid esters decompose when heated, giving off carbon dioxide, and yielding derivatives of acetic acid, $\text{C}(\text{C}_2\text{H}_5)_2(\text{COOH})_2 = \text{CO}_2 + \text{CH}(\text{C}_2\text{H}_5)_2\cdot\text{COOH}$. Moreover, the sodium derivative of the ester may be acted upon by iodine to give a tetracarboxylic ester, $\text{CH}(\text{COOC}_2\text{H}_5)_2\cdot\text{CH}(\text{COOC}_2\text{H}_5)_2$, and by repeating these processes, acids containing a large number of carboxyl groups have been synthesized.

Halogen Derivatives.—By the limited action of an alcoholic solution of an alkali on ethylene dibromide, the monobromo-substitution product of ethylene, vinyl bromide, $\text{CH}_2=\text{CHBr}$, can be isolated, but such derivatives containing the halogen linked to an unsaturated carbon atom do not show the reactivity of the saturated halogen products. The most important member of the unsaturated series is allyl iodide, $\text{CH}_2=\text{CH}\cdot\text{CH}_2\text{I}$, which is as reactive as the paraffinoid iodides.

Ethyl iodide dissolved in dry ether is rapidly acted upon by metallic magnesium to form a solution of magnesium ethyl iodide, $\text{C}_2\text{H}_5\cdot\text{MgI}$ [or $\text{C}_2\text{H}_5\cdot\text{MgI} + (\text{C}_2\text{H}_5)_2\text{O}$] (*see* GRIGNARD REAGENT), and when this acts on lead chloride, lead tetraethyl, $\text{Pb}(\text{C}_2\text{H}_5)_4$, or lead ethide, is formed. This substance is of importance as an "anti-knock" in petrol or gasoline, a suitable mixture being sold as the proprietary brand "Ethyl." Chloroform, CHCl_3 , prepared by the action of bleaching powder on alcohol, and iodo-

form, CHI_3 , by the interaction of iodine, alcohol and alkali, are used in medicine, the former as an anaesthetic, the latter an antiseptic. When acetic acid is chlorinated, it gives mono-, then di-, and finally tri-chloroacetic acid, $\text{CCl}_3\cdot\text{COOH}$, and all of these are very much stronger acids than acetic itself.

Sulphur Derivatives.—When the oxygen in, for instance, ethyl alcohol is replaced by sulphur, the resulting substance is called ethyl mercaptan, $\text{C}_2\text{H}_5\cdot\text{SH}$. It is prepared technically by the interaction of ethyl chloride and potassium hydrosulphide, KSH , and readily condenses with acetone, as follows:—

The resulting sulphur derivative, when oxidized by potassium permanganate, gives sulphonal, $(\text{CH}_3)_2\text{C}(\text{SO}_2\text{C}_2\text{H}_5)_2$, which is used as a hypnotic. When carbon disulphide is treated with alcoholic potash, potassium xanthate, $\text{C}_2\text{H}_5\cdot\text{O}\cdot\text{CS}\cdot\text{SK}$, is formed, which crystallizes in yellow needles, and derives its name from the yellow colour of its cuprous salt. Cellulose xanthate (viscose) is of great value for the preparation of artificial silk.

Derivatives Containing Nitrogen.—When ethyl iodide and alcoholic ammonia interact, the following amines are produced in the form of their hydriodides: ethylamine, $\text{C}_2\text{H}_5\text{NH}_2$; diethylamine, $(\text{C}_2\text{H}_5)_2\text{NH}$; and triethylamine $(\text{C}_2\text{H}_5)_3\text{N}$; together with tetraethylammonium iodide, $\text{N}(\text{C}_2\text{H}_5)_4\text{I}$. The salts of all except the last are readily decomposed by alkalis, and the separation of the organic bases is described under AMINES. The amines are stronger bases than ammonia, but very similar to it in their properties (*see* AMMONIA). The lower members are inflammable gases with an ammoniacal odour, soluble in water, giving alkaline solutions, and all form characteristic salts with acids.

The Acid-Amides (*q.v.*), of the general type $\text{R}\cdot\text{CO}\cdot\text{NH}_2$, are hydrolyzed by boiling alkalis to ammonia and the salt of the corresponding acid, whereas amines are completely unaffected by this treatment. Urea (*q.v.*), $\text{CO}(\text{NH}_2)_2$, the acid-amide of carbonic acid, obtained artificially in a memorable synthesis from ammonium cyanate by Wöhler in 1828, may also be synthesized by the action of ammonia on phosgene, COCl_2 . It is one of the most important of the final products of protein metabolism, and occurs in the urine of mammals; a human adult, for instance, excretes about 30 grams per day. The *nitriles*, $\text{R}\cdot\text{CN}$, and the *hydroxy-nitriles*, or *cyanohydrins*, e.g., acetaldehyde-cyanohydrin, $\text{CH}_3\cdot\text{CH}(\text{OH})\cdot\text{CN}$, have been previously discussed. The former on reduction give primary amines such as propylamine, $\text{C}_3\text{H}_7\cdot\text{CH}_2\cdot\text{NH}_2$. When the cyanohydrins are treated with ammonia, they are converted into amino-nitriles, e.g., $\text{CH}_3\cdot\text{CH}(\text{NH}_2)\cdot\text{CN}$, and on saponification, these yield the amino-acids.

The Amino-Acids are of great physiological importance since it has been shown that the proteins (*q.v.*) on hydrolysis yield a variety of acids belonging to this group. Glycine, glycocholl or amino-acetic acid, $\text{NH}_2\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$, the simplest representative of the class, is a solid melting at 232°C , soluble in water, and can be obtained by boiling glue with dilute sulphuric acid, or synthetically by the action of ammonia on mono-chloroacetic acid. By the hydrolysis of different proteins, a large number of amino-acids have been obtained and their constitution determined by synthesis. These acids have been very closely studied as a preliminary step in the attempts that have been made to synthesize the proteins themselves.

The Proteins are of profound biological importance, for they appear to be the essential constituents of the living cell, and are intimately bound up with the processes of life. Their molecular weight is very large, but no exact estimations have yet been made. The simplest proteins include such substances as the albumins, the plant globulins, and the albuminoids such as gelatin, or silk fibroin, caseinogen from cheese, etc. Conjugated proteins are such individuals as haemoglobin, etc. When boiled with concentrated hydrochloric acid, or with 25% sulphuric acid, they break down, giving various amino-acids. From all the proteins investigated by this method up to the present, 20 of these amino-acids have been isolated, that found most frequently being leucine, $(\text{CH}_3)_2\text{CH}\cdot\text{CH}_2\cdot\text{CH}(\text{NH}_2)\cdot\text{COOH}$. The conclusion that different proteins are built up of varying numbers of amino-acids is obvious,

and attempts have been made to reconstruct them, commencing with these simpler acids of known molecular structure. The result has been the synthesis of a group of substances called the *polypeptides*, of which the molecular architecture is therefore known, and some of which are of considerable molecular magnitude. They show many of the characteristic reactions of the proteins themselves but are not identical with them, so the constitution of this important group of substances is still unknown.

Laboratory Synthesis and Photosynthesis.—Throughout this summary of the aliphatic derivatives, many have been mentioned as occurring in the plant kingdom. It is well to point out that although a considerable number of these have been synthesized in the laboratory, and are identical in every respect with the natural products, the methods employed in their preparation are entirely different from those taking place in the living cell. The two sugars, dextrose and laevulose, and palmitic, stearic and malic acids, for instance, have been obtained synthetically, although starch, cellulose and the proteins have not. All these complex substances, however, are manufactured by the living cell from the carbonic acid present in the atmosphere, from nitrogenous material and various inorganic constituents in the soil, under the influence of moisture and with but slight variations of temperature, the energy required being obtained directly or indirectly from the sun; so that, without the last factor, the whole process would cease. Attempts have been made in the laboratory to imitate the reactions which are believed to take place in the living cell; these are meeting with an increasing measure of success, which should give rise to a new organic chemistry of great importance to man.

See advanced works on organic chemistry, and numerous articles in the *Journal and Annual Report* of the Chemical Society, *British Chemical Abstracts* and see also list of journals, in which original papers appear, in F. A. Mason, *Introduction to the Literature of Chemistry* (1924).

HOMOCYCLIC DIVISION

Organic compounds may be classified on the basis of molecular structure into two main divisions: (1) open-chain, aliphatic or *acyclic* compounds, and (2) closed-chain, or *cyclic* compounds. The latter division presents a great diversity of types: oxygen, nitrogen, sulphur and other elements may participate with carbon in manifold ways to form cyclic nuclei; the resulting ring-systems exhibit characters closely resembling open-chain compounds, in so far as they yield substitution derivatives and behave as compound radicals. In classifying closed-chain compounds, the first step consists in dividing them into (i.) carbocyclic, in which the closed chain, ring, or nucleus is composed solely of carbon atoms—these are known also as *homocyclic* or *isocyclic* on account of the identity of the members of the ring—and (ii.) *heterocyclic*, in which different elements go to make up the ring. A molecule containing two or more ring-systems, e.g., naphthalene or camphor, is said to be polycyclic.

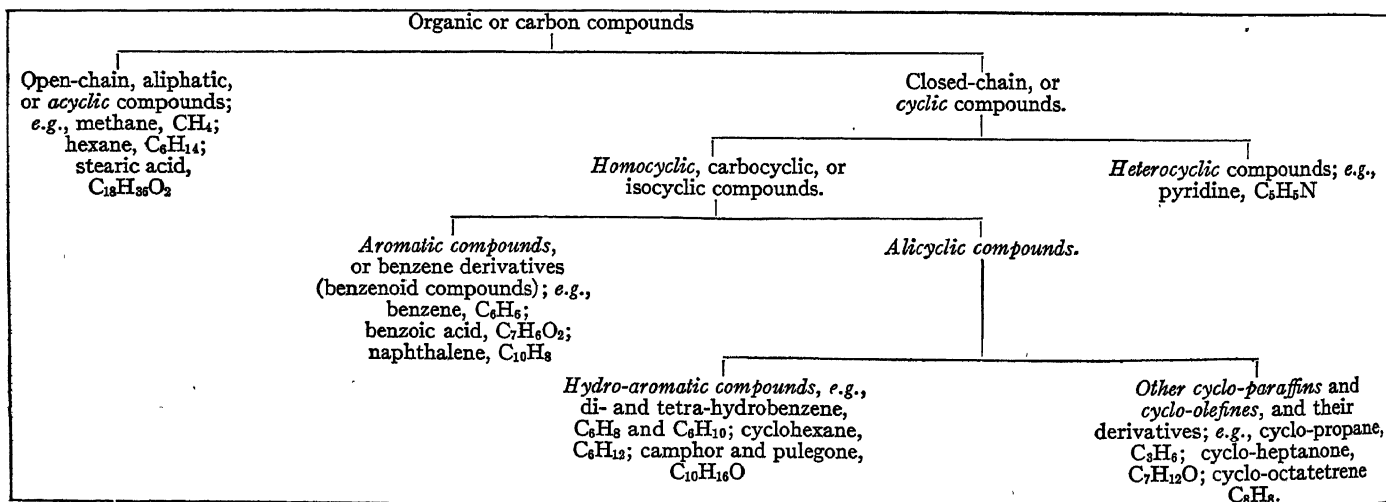

Homocyclic compounds may be conveniently subdivided into

(a) benzene derivatives, benzenoid compounds or *aromatic compounds* proper, and (b) *alicyclic compounds*. The homocyclic nucleus of benzene, C_6H_6 , and its derivatives invariably contain six carbon atoms associated with fewer hydrogen atoms (or their substituents) than suffice to satisfy the carbon valencies, the deficit being in all instances the equivalent of three double linkages; this peculiarity of structure is associated with the "benzenoid" or "aromatic" character which is shown also by certain similarly constituted heterocyclic compounds, such as pyridine, C_5H_5N . Alicyclic compounds do not exhibit the "aromatic" character, but, as indicated by their name, bear a general chemical resemblance to the aliphatic compounds.

The alicyclic subdivision embraces the important class of *cycloparaffins* or *polymethylenes* $(CH_2)_n$ and their derivatives, in which the nucleus contains three or more carbon atoms, all of which are fully saturated. In addition, it comprises a similar range of *cyclo-olefines* and their derivatives, in which the carbon nucleus contains one or more olefinic linkages (double bonds). The most important members of these two classes, like the aromatic compounds, contain a nucleus composed of six carbon atoms: it is convenient to classify these six-membered-ring compounds under the special heading of *hydroaromatic compounds*. A particular significance thus attaches to all homocyclic compounds containing six carbon atoms in the ring; i.e., to the aromatic compounds and the hydroaromatic compounds. A summarized scheme of classification is appended:

Aromatic Compounds.—The presence of a closed chain, or ring, in an organic molecule was first suggested for benzene by Kekulé, in 1865. The representation of this hydrocarbon and its innumerable derivatives as closed-chain compounds has been termed the crowning achievement of the doctrine of the linking of carbon atoms (Japp, *Chemical Society's Memorial Lectures*, 1901). The benzene derivatives, or aromatic compounds, form the most important and most numerous class of homocyclic compounds; it has been stated, indeed, that three-quarters of organic chemistry is concerned with benzene and its derivatives, and that the benzene ring is the most familiar emblem in scientific literature. Most of these substances are purely synthetic in origin, and became known as a result of the enormous volume of research upon coal-tar components which followed the synthesis of the first coal-tar dye by W. H. Perkin, Sr., in 1856. Organic chemical research for more than 50 years after Perkin's discovery centred mainly around the synthetic production of aromatic compounds from benzene and related coal-tar components. These derivatives are of great scientific and industrial interest; but although the benzene nucleus is found in most of the natural organic colouring matters and in numerous other plant and animal products, it does not possess the biochemical importance of the open-chain and other non-benzenoid structures of carbohydrates, fats and proteins.

The treatment of aromatic compounds will be restricted mainly to a general consideration of their structure and fundamental

chemical characteristics; specific information concerning important individual compounds should be sought under their names and under such headings as AZO-COMPOUNDS and DIAZO-COMPOUNDS; NITRO-COMPOUNDS, QUINONES and DYES, SYNTHETIC.

Sources of Aromatic Compounds.—The origin of the name "aromatic" may be traced to the fact that many of the aromatic spices and fragrant oils of plants contain benzene derivatives; only a limited number of these derivatives, however, are characterized by an aromatic odour. Benzene and homologous hydrocarbons occur also in natural petroleum, particularly in those of Borneo and Papua. By far the most important source of aromatic compounds is coal-tar, of which coal yields from 4 to 7% when destructively distilled in horizontal retorts at 900–1100° C, as in the manufacture of coal-gas. Coke-oven tar is very similar in composition to gasworks tar, but the carbonization of coal at lower temperatures, or in vertical retorts, furnishes tars in which the aromatic substances are replaced largely by paraffins and naphthenes (*vide infra*). Gasworks coal-tar contains some 300 substances, but of these only about ten are isolated for common use as "primaries," in the synthesis of coal-tar dyes, medicinal chemicals, perfumes, high explosives and other aromatic compounds of industrial importance. When submitted to nitration, sulphonation, chlorination, oxidation and other chemical processes, the "primaries" give rise to "intermediates" (of which several hundreds are manufactured) and these by further treatment, which often includes an interaction between two intermediates or their derivatives, yield the finished synthetic dyestuffs (*q.v.*) and related "coal-tar chemicals." The most important primaries are the four aromatic hydrocarbons, benzene, toluene, naphthalene and anthracene, together with phenol (carbolic acid) or hydroxybenzene. These are separated from the tar by repeated fractional distillation, supplemented by appropriate chemical treatment. Coal yields only about 0.5% of the five chief primaries; *i.e.*, about 11 lb. per ton, of which naphthalene forms approximately two-thirds, benzene together with toluene one-fifth, and phenol and anthracene each one-fifteenth.

Benzene.—Benzene (*q.v.*), C_6H_6 , is theoretically the fundamental substance from which all the aromatic compounds are derived; it is also the most economical practical source of many of them: these two facts combine to render benzene one of the most outstanding of all organic compounds. Much study has accordingly been devoted to its physical and chemical properties and to the satisfactory representation of these properties by means of a structural or constitutional formula. Benzene was discovered in 1825 by Michael Faraday, in an illuminating gas prepared from fish oils, and its presence in coal-tar was established by A. W. Hofmann, in 1845; but it was not until 1865 (seven years after the publication of the theory of molecular structure) that Kekulé arrived at his conception of the benzene ring, or closed chain, of six carbon atoms. This delay was due to the difficulty of giving an adequate structural interpretation of the fundamental chemical differences which exist between aromatic and aliphatic compounds; differences which it is essential to include in a general review of the chemical behaviour of benzene and its derivatives before proceeding to a discussion of its molecular structure.

Chemical Behaviour of Aromatic Compounds.—In comparison with hexane, C_6H_{14} , the molecule of benzene lacks eight hydrogen atoms; but in spite of the high unsaturation indicated by its molecular formula, benzene is a particularly stable substance. It is affected only very slowly by oxidizing agents, and is indifferent towards hot dilute acids and alkalis, bromine water or the ordinary reducing agents. In these respects it differs profoundly from the isomeric open-chain compound, dipropargyl,

which has all the chemical properties of a highly unsaturated substance. More striking still, the typical reactions of benzene are substitution reactions. Benzene derivatives may be regarded as formed through the replacement of the hydrogen atoms of benzene by other elements, groups or radicals; and in this respect they resemble the substitution products of saturated aliphatic hydrocarbons. They are often produced, however, by reactions

peculiar to the aromatic series. Ability to undergo direct nitration and sulphonation is especially characteristic of aromatic compounds. Thus, benzene and its homologues react readily with (a) a mixture of concentrated nitric and sulphuric acids ("nitrating mixture" or "nitrating acid") and (b) fuming sulphuric acid, to yield nitro-derivatives and sulphonic acids, respectively; the nitration and sulphonation of benzene are represented by the following equations:

The corresponding aliphatic derivatives usually have to be prepared by indirect processes. In the presence of certain catalytic agents (halogen carriers), benzene and its homologues may also be chlorinated and brominated, the process being again one of substitution:

Evidence of a certain type of unsaturation in the aromatic molecule is provided by the capacity of benzene and its derivatives to form substitution products under special conditions. When exposed to bright sunlight (in the absence of a halogen carrier), benzene combines with a maximum proportion of six atoms of chlorine or bromine per molecule, to form benzene hexachloride and hexabromide, $C_6H_2Cl_6$ and $C_6H_2Br_6$; it also forms a triozonide, ozobenzene, $C_6H_2(O_3)_3$; but it is unable to combine, like the olefines, with hydrogen chloride, hypochlorous acid, etc. Benzene also undergoes catalytic hydrogenation (*q.v.*) in presence of finely divided nickel, forming cyclohexane, C_6H_{12} ; but this substance reverts to benzene upon oxidation. Thus benzene differs profoundly from ethylene and other unsaturated open-chain compounds in possessing a greater stability than its reduction product.

Besides exhibiting distinctive reactions—in particular, ready nitration and sulphonation—aromatic compounds differ from aliphatic compounds by virtue of their higher proportion of carbon and their greater tendency to solidify. No aromatic compound proper contains fewer than six carbon atoms in the molecule, and the more complex members tend to break down thus far when submitted to oxidation and other disintegrative processes; further oxidation of the resulting C_6 -complex then usually disrupts the molecule at a stride to carbon dioxide and other simple substances. Thus, anthranilic acid, $C_7H_7O_2N$, yields aniline, C_6H_7N , and carbon dioxide when heated; and naphthalene, $C_{10}H_8$, upon oxidation gives phthalic acid, $C_8H_6O_4$, which when heated with lime is degraded further to benzene. Such changes point to the presence in the molecules of benzene and its derivatives of a stable nucleus containing six carbon atoms.

Equivalence of the Six Hydrogen Atoms in Benzene.—That the six hydrogen atoms in the molecule of benzene are similarly situated may be inferred from the fact that isomerism does not occur among monosubstituted benzenes of the general formula C_6H_5X ; thus, only one bromobenzene, C_6H_5Br , one nitrobenzene, $C_6H_5NO_2$, and one benzoic acid, C_6H_5COOH , are known. This equivalence, which was assumed by Kekulé, was first demonstrated by Ladenburg in 1874. It is unnecessary to detail the formal experimental proof, but the underlying principle may be illustrated by referring to the isomeric nitrobenzoic acids, $NO_2 \cdot C_6H_4 \cdot COOH$, of which three are known. When the nitro-group is replaced experimentally by a hydrogen atom, all three isomerides yield one and the same substance, *viz.*, benzoic acid; thus in all three cases the carboxyl group, $-COOH$, may be assumed to have taken the position originally occupied by a particular hydrogen atom (*a*) of the molecule of benzene. The existence of three distinct nitrobenzoic acids shows that after the introduction of the carboxyl group the remaining five hydrogen atoms of the original benzene molecule are not equivalent; denoting these atoms by the letters (*b*) to (*f*), it may be assumed further that hydrogen atoms (*b*), (*c*) and (*d*), respectively, have

been replaced by the nitro-group in the three nitrobenzoic acids, which may now be represented as follows:

Each of these acids when distilled with lime yields nitrobenzene, $\text{C}_6\text{H}_5\text{NO}_2$, and since the product is identical in all three cases it follows that three of the hydrogen atoms of the original molecule of benzene—namely, (b), (c) and (d)—are equivalent. An extension of this principle has shown that the replacement of any one of the six hydrogen atoms by the same atom or group leads to an identical product.

Isomerism of Benzene Derivatives.—A large volume of experimental evidence indicates that disubstitution products of benzene, whether of the type $\text{C}_6\text{H}_4\text{X}_2$ or $\text{C}_6\text{H}_4\text{XY}$, can exist in three isomeric forms, as indicated above for the nitrobenzoic acids, in which $\text{X}=\text{NO}_2$ and $\text{Y}=\text{COOH}$. Trisubstitution products of the type $\text{C}_6\text{H}_3\text{X}_3$ are found to be capable of existence in three isomeric forms, as are also tetra-substituted benzenes, $\text{C}_6\text{H}_2\text{X}_4$, in which the four substituents are identical; only one derivative is known for each of the types C_6HX_3 and C_6X_6 .

The Benzene Ring.—"I was sitting, writing at my text-book; but the work did not progress; my thoughts were elsewhere. I turned my chair to the fire and dozed. Again the atoms were gambolling before my eyes. This time the smaller groups kept modestly in the background. My mental eye, rendered more acute by repeated visions of the kind, could now distinguish larger structures, of manifold conformation: long rows, sometimes more closely fitted together; all twining and twisting in snake-like motion. But look! What was that? One of the snakes had seized hold of its own tail, and the form whirled mockingly before my eyes. As if by a flash of lightning I awoke; and this time also I spent the rest of the night in working out the consequences of the hypothesis." These are the words in which Kekulé described the way in which the conception of the benzene ring came to him (*v. Japp, loc. cit.*). The equivalence of the six hydrogen atoms and the isomerism of the substituted benzenes had not been established at that time (1865); but both of these fundamental characteristics of the benzene structural assemblage are at once accounted for when the molecule is represented as a closed chain, or ring, of six carbon atoms, each of which is associated with one hydrogen atom. The ring may be represented by a circle, or, more conveniently, in one of the following ways:

The disposal of the fourth valency of each carbon atom, which is not indicated in these symbols, will be discussed later; for the time being it is sufficient to state that the benzene "ring," however it may be represented, stands as an expression of a completely symmetrical structure in which all six hydrogen atoms are equivalent. The hexagon is in general use as an abbreviated symbol for the benzene molecule; it is assumed that at each corner there is a CH group; the substitution of a hydrogen atom is shown by attaching the replacing atom or group (*i.e.*, the substituent) to the corner concerned, as shown below. For purposes of systematic nomenclature the six carbon atoms are numbered consecutively:

From the second of these formulae it is apparent that the introduction of a substituent in place of any one of the six equivalent hydrogen atoms at once destroys the equivalence of the remaining five, and creates three kinds of positions in the new molecule. The two similar positions (2, 6) adjacent to the substituent are known as ortho-positions, with respect to the substituent; the single position (4) diametrically opposite the substituent is called the para-position; and the two remaining positions (3, 5), which are similar, are distinguished by the prefix meta. It is obvious, therefore, that disubstituted benzenes should exist in three isomeric forms; and this consequence of Kekulé's theory is in accordance with the facts already outlined. The three nitrobenzoic acids may thus be represented and named as follows, the prefixes *o*-, *m*-, and *p*- being the recognized contractions for ortho-, meta-, and para-, respectively:

Di- and poly-substituted benzenes related in this way are known as *position isomerides*. It will be seen that 1, 2-nitrobenzoic acid is identical with 1, 6-nitrobenzoic acid, and 1, 3-nitrobenzoic acid with 1, 5-nitrobenzoic acid. It may be added that the closed chain of six carbon atoms, known as the *benzene nucleus*, accounts for the observed isomeric relationships of all types of substitution products of benzene.

The number of isomerides of various types when all the substituent groups are alike has been indicated above. When the groups are unlike a greater number is possible, except in the case of di-derivatives. When two of three substituents are alike, six isomerides are possible, as in the case of the diaminobenzoic acids, $\text{C}_6\text{H}_3(\text{NH}_2)_2\text{COOH}$. When all three are unlike, ten isomerides are possible; thus ten hydroxytoluic acids, $\text{CH}_3\text{C}_6\text{H}_3(\text{OH})\text{COOH}$, are known. In the case of tetra-substituted compounds, 30 isomerides are possible when all the groups are different. Of the trisubstitution derivatives, the 1, 2, 3-compounds are known as "adjacent" or "vicinal" (*v*), the 1, 2, 4- as "asymmetrical" (*as*), and the 1, 3, 5- as "symmetrical" (*s*). The same three terms are applied to tetra-substituted derivatives having the groups in the 1, 2, 3, 4-, 1, 2, 3, 5- and 1, 2, 4, 5-positions, respectively.

Disposal of the Fourth Valency.—Although, very rarely, the carbon atom may exhibit tervalency, as in triphenylmethyl (*vide infra*), there are no grounds for assigning this exceptional valency to the carbon atoms of benzene. Kekulé's original formula (1866) showed the six carbon atoms attached to one another by alternate single and double bonds, as shown in formula (I.):

It may be said at once that despite much criticism this original formula is quite as convenient as any of its modifications, especially in the consideration of syntheses and decompositions of the benzene nucleus. The physical properties are also in keeping with Kekulé's formula, and although benzene is not visibly coloured it exerts a strong selective absorption in the ultra-violet region of the spectrum. The lack of resemblance between benzene and tri-olefines may be ascribed to some extent to the fundamental difference in structure between a symmetrical ring and an open chain:

whilst to meet the further objection that isomeric 1, 2-disubstitution products corresponding to formulae (A) and (B) do not exist, Kekulé (1872) suggested a dynamic formula (II.), which represents a rapid oscillation between two tautomeric forms and is curiously reminiscent of his original vision of a structure "twinning and twisting in snake-like motion":

Meanwhile Dewar (1866) proposed an unsymmetrical formula (III.). This has an interest at the present time, since it illustrates a relationship of benzene to the important group of quinonoid colours; it appears also to have a bearing upon the puckering of the benzene ring which has been indicated by the X-ray analysis of benzene crystals. Dewar's formula, moreover, finds support, as representing a possible phase of the benzene molecule, in J. F. Thorpe and C. K. Ingold's recent work on intra-annular tautomerism. A "diagonal" formula was suggested by Claus (1867) and a "prism" formula by Ladenburg (1869); but more importance attaches to the so-called "centric" formula (IV.) of H. E. Armstrong and A. Baeyer (1887):

A strong argument against the ethylene linkages of Kekulé's formula is provided by the remarkable stability of all benzenoid compounds towards oxidizing and reducing agents and towards halogens and haloid acids. The widely different behaviour of hydroaromatic compounds, containing either one or two ethylene linkages (which behave towards these reagents exactly as unsaturated aliphatic compounds) suggests that in benzenoid compounds the fourth valencies are symmetrically distributed in such a manner as to induce a peculiar stability in the molecule. The centric formula assumes that the fourth valencies are simply directed towards the centre of the ring, thereby undergoing a mutual saturation; the formula is thus less rigid and precise than most of the others.

More recently (1899), Thiele's theory of partial valencies (*see* VALENCY) has been applied to the benzene structure with considerable success. Thiele's formula (V.) represents the benzene molecule as a particular combination of the so-called conjugated systems which were first studied in open-chain compounds; the centric formula, on the other hand, has been criticized as an *ad hoc* representation calling for a novel system of valencies and a unique distribution of affinity. According to Thiele, benzene is to be represented as a closed series of conjugated double bonds, which, since it possesses no free partial valencies, is devoid of unsaturated characteristics. "As by the neutralization of the partial valencies the original three double bonds vanish, no distinction can be drawn between them and the secondary (conjugated) double bonds. Benzene contains six inactive double bonds. Thus, the difficulty presented by the two ortho-positions, which Kekulé attempted to meet by the aid of his dynamic hypothesis, disappears" (Thiele). Moreover, the appearance of partial valencies in di- and tetra-hydrobenzene, and hydroaromatic compounds in general, explains the resemblance of these compounds to unsaturated open-chain compounds:

Spatial Configuration of Benzene.—According to the space theory of Le Bel and van 't Hoff (*see* STEREOCHEMISTRY), the six hydrogen atoms of benzene must either be permanently co-planar or capable of easy passage through a co-planar phase. If this were not the case, substitution derivatives (in which none of the substituents contain asymmetric atoms) should exist in enantiomorphous forms, differing in their action on polarized light: such optical isomerism has not been established, in spite of exhaustive experiments. Most of the formulae given above fulfil this condition when interpreted in terms of the theory of the tetrahedral environment of the carbon atom; but Ladenburg's prism configuration, which requires optical isomerism for ortho-disubstituted benzenes, is thereby ruled out. The modern tendency is to regard the molecule of benzene as a vibratory system passing through a number of phases, some of which are represented closely by the formulae of Kekulé, Armstrong-Baeyer, and others. This view was elaborated by Collie (1897), who suggested a spatial configuration consisting of a symmetrical grouping of two triplets of CH groups, each placed at the apex of a regular octahedron; the successive vibration-phases of the molecule, obtained by simple rotation of the space-model, are then represented in plane projection as follows:

Electronic representations of the benzene molecule, based on the modern ideas of atomic structure and valency, have also been advanced. For all ordinary purposes the original representation of Kekulé remains quite as convenient as any of the proposed modifications; and, aromatic characteristics of homocyclic compounds are thus to be associated with cyclic structures of six atoms which are capable of assuming a symmetrical arrangement of alternate single and double bonds. Cyclo-octatetrene, C_8H_8 , which conforms to the last requirement, but possesses a ring of eight carbon atoms, is not aromatic in character (R. Willstätter, 1911). Since, apart from the consideration of additive reactions, it is usually possible to ignore the disposition of the fourth valencies, the simple hexagon provides a convenient symbol for the benzene molecule. It may be added that the purely physical researches of Sir W. H. Bragg and W. L. Bragg have demonstrated conclusively the presence of a six-carbon-atom ring not only in benzenoid molecules but also in crystallized carbon (diamond and graphite) itself. "When we consider the diamond construction we cannot but notice the striking appearance, in every part of the model, of an arrangement of the carbon atoms in a ring of hexagonal form. If we take one of these rings out from the model, it has the appearance of a perfect hexagon when viewed from above, but not a flat ring. There are layers in graphite as in the diamond structure . . . from above it presents the same appearance of a hexagonal network. Recent experiments seem to show that the layers have been flattened out, so that each carbon is now surrounded by three atoms in its own plane. . . . Whether the benzene ring is actually puckered under all circumstances, or is sometimes flat, we find it difficult at present to say." (W. H. Bragg.)

Orientation of Substituent Groups in the Benzene Ring.—The

determination of the relative positions of the substituents in the molecule of a benzene derivative constitutes an important factor in the general investigation of such compounds; the process is known as orientation (*orienté*, situated). Since, as a rule, if high temperatures are avoided, a replacing group enters the nucleus in the position formerly occupied by the replaced group, any compound which can be obtained from or converted into a standard substance, for which the relative positions of the substituents are known, may be definitely orientated. Benzene derivatives of known constitution are now so numerous that this method may be readily applied; but originally the number of standard compounds was very small. Among the earliest derivatives to be orientated in this way were the benzenedicarboxylic acids (phthalic acids), $C_6H_4(COOH)_2$. The ortho-acid was orientated by Graebe (1869), owing to its production from naphthalene by oxidation (*vide infra*). The meta-acid was correlated with mesitylene, which by reason of its formation from acetone (*q.v.*) by condensation must be regarded as 1, 3, 5-trimethylbenzene (Ladenburg, 1875). Upon oxidation, mesitylene yields the monobasic mesitylenic acid; this when distilled with lime loses carbon dioxide and gives a dimethylbenzene (xylene), which must obviously be the meta-compound; and this in turn yields meta-phthalic acid when oxidized:

The third isomeric phthalic acid is thus, by elimination, the para-compound. The orientation of the two remaining xylenes also follows from their oxidation to *o*- and *p*-phthalic acid, respectively.

Körner's "absolute method" (1874) renders it unnecessary to make any assumptions respecting the constitution of standard compounds, such as *o*-phthalic acid and mesitylene. Starting with the three isomeric dibromobenzenes, $C_6H_4Br_2$, he found that when converted into tribromobenzenes, $C_6H_3Br_3$, the first isomeride gave only one tri-derivative; the second gave two; and the third gave three: from the following formulae, in which equivalent positions for the third bromine atom are denoted by identical numerals, it is obvious that the first dibromobenzene was the para-compound, the second the ortho-, and the third the meta-:

The method is generally applicable, but in actual practice it is often difficult to isolate all the various isomerides, since some may be produced in very small proportions. It will be seen that a simultaneous orientation of the tri-derivatives is accomplished; thus, the sole tri-derivative yielded by para-dibromobenzene is 1, 2, 4-tribromobenzene. The same fundamental idea may be utilized by eliminating one and the same group from each of a complete series of isomeric tri-derivatives; thus, when the carboxyl group is eliminated from each of the six possible diamino-benzoic acids, $C_6H_4(NH_2)_2COOH$, the resulting diamino-benzene, $C_6H_4(NH_2)_2$, from one only of these acids is the para-compound; from two, the ortho-; and from three, the meta- (Griess, 1874). The orientation of higher substitution derivatives is determined by considering the di- and tri-substitution compounds into which they may be transformed.

Orientating Influence of Substituents in the Benzene Ring.—When a second substituent is attached to the nucleus of a non-substituted benzene it may enter in one of three positions to form the *ortho*-, *para*- or *meta*-compound. *A priori*, it might be imagined, for example, that upon nitrating toluene (methylbenzene), $CH_3\cdot C_6H_5$, with one equivalent proportion of nitrating mixture, an equi-molecular mixture of *o*-, *m*- and *p*-nitrotoluene, $CH_3\cdot C_6H_4\cdot NO_2$, would be produced. As a matter of fact, the prod-

uct consists mainly of *o*- and *p*-nitrotoluene, with only about 3% of *m*-nitrotoluene. Thus the substituent originally present in the molecule, *i.e.*, the methyl group, has exerted a pronounced directive action, or *orientating influence*, upon the entering substituent. Again, when nitrobenzene, $C_6H_5\cdot NO_2$, is nitrated further it yields *m*-dinitrobenzene, $C_6H_3(NO_2)_2$, to the almost entire exclusion of the *o*- and *p*-derivatives. Thus while the methyl group favours entry to the *o*- and *p*-positions, the nitro-group dominates the *m*-position; or, in other words, the methyl group exerts the *ortho*-*para* orientating influence while the nitro-group exerts the *meta* orientating influence. Such observations indicate a close relationship between the *ortho*- and *para*-positions, which are clearly differentiated from the *meta*-position. The result is independent of the nature of the second group introduced. Experience has shown that as a general rule the *ortho*-*para* influence is exerted by hydrocarbon radicals, halogen atoms, and saturated groups such as $-OH$ and $-NH_2$; while the *meta* influence is associated with unsaturated groups, such as $-NO_2$, $-SO_3H$, $-COOH$, $-CHO$, $-CN$ and $-CO\cdot CH_3$. As a rule, the former groups facilitate further substitution in the benzene nucleus, while members of the second class hinder further action. A working guide to orientating influence is also provided by the empirical rule of Crum Brown and Gibson (1892): if the hydrogen compound, HX , of the substituent, X , already present in the benzene nucleus can be directly oxidized to HXO , then *meta*-derivatives predominate in further substitution; if not, *ortho*- and *para*-derivatives predominate. For example, since hydrobromic acid cannot be directly oxidized to hypobromous acid, bromobenzene yields mainly *ortho*- and *para*-disubstituted benzenes. It follows from what has been said that the order of introducing substituents into the benzene nucleus is of importance; *e.g.*, the bromination of nitrobenzene yields almost exclusively *m*-bromonitrobenzene, whilst the nitration of bromobenzene leads to the formation of the isomeric *o*- and *p*-bromonitrobenzenes, the product consisting of 35% of the former and 65% of the latter. When a third substituent is introduced into a disubstituted nucleus, the orientating influence of the two groups already present may either be conjoined or opposed, depending upon their nature and relative positions.

No completely satisfactory mechanism has yet been devised to account for the complex phenomena of orientation. Hypotheses have been advanced by J. N. Collie, B. Flürscheim, A. F. Hollman and others; and more recently attempts have been made to base explanations upon the electronic theory of valency. The phenomena are closely associated with the mutual influence exerted between substituents in the benzene nucleus. Thus, the reactivity of nuclear-substituted halogen is greatly enhanced by the presence of a nitro-group in the *ortho*- or *para*-position to it; no influence of the kind, however, is exerted by a nitro-group in the *meta*-position. An *ortho*-substituent often diminishes the reactivity of the neighbouring substituent, but this effect is due largely to *steric hindrance*, contingent upon the spatial proximity of the groups: for example, di-*ortho*-substituted benzoic acids of the type $C_6H_3X(1)COOH(2)Y(3)$ cannot usually be esterified with alcohol and hydrogen chloride (V. Meyer, 1894).

Synthesis and Fission of the Benzene Ring.—(1) The characteristic distinctions which exist between aliphatic and benzenoid compounds make the transformations of one class into the other particularly interesting. In the first place, many aliphatic compounds, including simple substances like methane and tetrachloromethane, show a tendency to yield aromatic compounds when subjected to a high temperature, in so-called pyrogenetic reactions; the predominance of aromatic compounds in ordinary coal-tar is probably to be associated with the occurrence of similar pyro-condensations. The termolecular polymerization (*q.v.*) of numerous acetylene compounds to form derivatives of benzene is of considerable interest. M. P. E. Berthelot (1870) first synthesized benzene by passing acetylene through tubes heated to dull redness; at higher temperatures the action becomes reversible, the benzene yielding diphenyl, diphenylbenzene and acetylene. The condensation of acetylene to benzene is also possible at ordinary temperatures in the presence of pyrophoric iron, finely divided nickel, spongy platinum and other catalysts (P. Sabatier and J. B.

Senderens). The homologues of acetylene condense more readily; thus allylene yields trimethylbenzene merely under the influence of sulphuric acid:

The "potassium carbon monoxide" obtained by Liebig (1834) through the action of carbon monoxide on heated potassium was later (1885) found to yield hexahydroxybenzene, $\text{C}_6(\text{OH})_6$, when treated with dilute acid; further investigation of this compound brought to light a number of highly interesting derivatives (see QUINONES). Mellitic acid, or benzene-hexacarboxylic acid, $\text{C}_6(\text{COOH})_6$, first obtained from the mineral honeystone (aluminium mellitate) by Klaproth, in 1799, was afterwards (1883) prepared by the oxidation of graphite or charcoal with alkaline permanganate; this result is of particular interest when correlated with recent work on the crystalline structure of graphite (*vide supra*). A large and important series of condensations may be effected by eliminating the elements of water between carbonyl (CO) and methylene (CH_2) groups. A fundamental and historic example is that of the condensation of three molecules of acetone, in the presence of sulphuric acid, to one molecule of mesitylene (*s*-trimethylbenzene) and three molecules of water; this reaction, which was first observed by Kane, in 1837, is represented below:

The condensation of geranial (citral) to cymene (*p*=isopropyl methylbenzene) is noteworthy: $\text{C}_{10}\text{H}_{16}\text{O} = \text{CH}_3 \cdot \text{C}_6\text{H}_4 \cdot \text{CH}(\text{CH}_3)_2 + \text{H}_2\text{O}$. The foregoing syntheses lead directly to a true benzene ring; but there are many reactions by which aliphatic compounds yield cyclic compounds with reduced benzene rings, from which true benzenoid compounds may then be prepared. An important example is the condensation, upon heating, of sodiomalonic ester, $\text{CHNa}(\text{COOC}_2\text{H}_5)_2$, to phloroglucinoltricarboxylic ester, a substance which gives phloroglucinol (*s*-trihydroxybenzene) when fused with alkalis.

(2) The relative stability of the benzene nucleus invests the question of its fission, or disruption, with a peculiar interest. Kekulé's formula indicates the possibility of a successive fission of the three double linkages, with the production of open-chain compounds. Fission usually occurs at more than one point; so that the six carbon atoms of the nucleus are rarely preserved as an unbroken open chain.

Certain aromatic compounds withstand ring decomposition more strongly than others; thus, benzene and its homologues, and also carboxylic acids and nitro-compounds, are much more stable towards oxidizing agents than amino- and hydroxy-benzenes, aminophenols, quinones and hydroxycarboxylic acids.

Decompositions by strong oxidation to carbon dioxide, formic acid, oxalic acid, etc., are of little interest. More important is the hydrolysis of benzene triozone (ozobenzene), $\text{C}_6\text{H}_6(\text{O}_3)_3$, to glyoxal, $\text{CHO} \cdot \text{CHO}$, since this disruption, suggestive of three double bonds in the ring, has been advanced as evidence in favour of Kekulé's formula: $\text{C}_6\text{H}_6(\text{O}_3)_3 + 3\text{H}_2\text{O} = 3\text{CHO} \cdot \text{CHO} + 3\text{H}_2\text{O}_2$. Tartaric acid, containing a chain of four carbon atoms in its molecule, has been obtained by oxidizing 1, 2-dihydroxybenzene (catechol) and hydroxybenzene (phenol) with nitrous acid and dilute potassium permanganate, respectively. 1, 3-dihydroxybenzene (resorcinol) when successively reduced and oxidized yields glutaric acid, $\text{HOOC} \cdot (\text{CH}_2)_3 \cdot \text{COOH}$, with five carbon atoms in the chain. An open-chain compound with six carbon atoms

may be had, for example, from 1, 4-dihydroxybenzene (hydroquinone); whilst salicylic acid, or 1, 2-hydroxybenzoic acid, $\text{C}_6\text{H}_4(\text{OH}) \cdot \text{COOH}$, when reduced by sodium in amyl alcohol yields *n*-pimelic acid, $\text{HOOC} \cdot (\text{CH}_2)_5 \cdot \text{COOH}$, an aliphatic compound whose molecule contains, in the form of a seven-membered open chain, the one substituent and six nuclear carbon atoms of the original aromatic molecule.

Chemical Characteristics of Nucleus and Side-chain in Aromatic Compounds.—Aliphatic chains, and also single groups containing carbon, when attached to a nuclear atom of a ring compound, are known as *side-chains*. Thus the molecules of toluene (methylbenzene) and cumene (isopropylbenzene) each contain one side-chain, while that of mesitylene (*s*-trimethylbenzene) contains three. The substituent radical, $-\text{NH} \cdot \text{CO} \cdot \text{CH}_3$, of acetanilide, $\text{C}_6\text{H}_5 \cdot \text{NH} \cdot \text{CO} \cdot \text{CH}_3$, also is called a side-chain; but the term does not usually comprise simple groups which do not contain carbon, such as $-\text{NO}_2$, $-\text{SO}_3\text{H}$, $-\text{OH}$ and $-\text{NH}_2$. Side-chains attached to the nucleus by carbon atoms may be oxidized to carboxyl, $-\text{COOH}$: thus *o*-xylene, $\text{C}_6\text{H}_4(\text{CH}_3)_2$, upon oxidation yields successively *o*-toluic acid, $\text{C}_6\text{H}_4(\text{CH}_3) \cdot \text{COOH}$, and *o*-phthalic acid, $\text{C}_6\text{H}_4(\text{COOH})_2$; while the isomeric ethylbenzene, $\text{C}_6\text{H}_5 \cdot \text{CH}_2 \cdot \text{CH}_3$, yields only benzoic acid, $\text{C}_6\text{H}_5 \cdot \text{COOH}$. The basicity of the final aromatic acid obtained upon oxidation thus indicates the number of carbon-linked side-chains in the original molecule. Moreover, halogen atoms present in the side-chains are removed in the oxidation, while nuclear halogen atoms remain; for example, benzyl chloride, $\text{C}_6\text{H}_5 \cdot \text{CH}_2\text{Cl}$, oxidizes to benzoic acid, while the isomeric *o*-chlorotoluene, $\text{Cl} \cdot \text{C}_6\text{H}_4 \cdot \text{CH}_3$, yields *o*-chlorobenzoic acid, $\text{Cl} \cdot \text{C}_6\text{H}_4 \cdot \text{COOH}$.

In *mixed aliphatic-aromatic compounds*, like toluene, $\text{CH}_3 \cdot \text{C}_6\text{H}_5$, the aliphatic side-chains retain the characters of their class, while the benzenoid nuclei retain their aromatic properties. Thus toluene is readily oxidized to benzoic acid, as stated above, the aromatic residue remaining unattacked. Nitric and sulphuric acids, on the other hand, affect only the nucleus, producing *o*- and *p*-nitrotoluenes, $\text{CH}_3 \cdot \text{C}_6\text{H}_4 \cdot \text{NO}_2$, and *o*- and *p*-toluene-sulphonic acids, $\text{CH}_3 \cdot \text{C}_6\text{H}_4 \cdot \text{SO}_3\text{H}$, by the usual processes of substitution. Chlorination may result in the formation of derivatives substituted either in the aromatic nucleus or in the aliphatic side-chain. The former substitution occurs more readily, *o*- and *p*-chlorotoluenes, $\text{CH}_3 \cdot \text{C}_6\text{H}_4 \cdot \text{Cl}$, being produced; while the latter substitution, which needs an elevation in temperature or other auxiliary, yields benzyl chloride, $\text{C}_6\text{H}_5 \cdot \text{CH}_2\text{Cl}$, benzal chloride, $\text{C}_6\text{H}_5 \cdot \text{CHCl}_2$, and benzotrichloride, $\text{C}_6\text{H}_5 \cdot \text{CCl}_3$.

Halogen atoms in the side-chain are very reactive, resembling in this respect the halogen atoms of alkyl halides; nuclear halogen atoms, on the contrary, are normally unreactive. Thus, benzyl chloride, $\text{C}_6\text{H}_5 \cdot \text{CH}_2\text{Cl}$ is readily hydrolyzed by aqueous alkali, forming benzyl alcohol, $\text{C}_6\text{H}_5 \cdot \text{CH}_2\text{OH}$; but the isomeric chlorotoluenes, $\text{CH}_3 \cdot \text{C}_6\text{H}_4 \cdot \text{Cl}$, are unaffected by this treatment. Further differences become apparent when various other typical aliphatic and aromatic derivatives are compared. The introduction of hydroxyl groups into the benzene nucleus gives rise to compounds generically named *phenols*, which, although resembling the aliphatic alcohols in their origin, differ from these substances in their increased chemical activity and their acid nature. Structurally, the phenols resemble the tertiary alcohols, since the hydroxyl group is linked to a carbon atom which is united to other carbon atoms by its three remaining valencies; hence on oxidation, instead of yielding corresponding aldehydes, ketones or acids, they undergo nuclear fission, as indicated above.

The *amines*, or amino-compounds, also exhibit striking differences. In the aliphatic series these compounds may be formed directly from the alkyl halides and ammonia, but in the benzene series this reaction is impossible unless the nuclear halogen atom be weakened by the presence of other substituents; *e.g.*, nitro-groups. Thus, primary aromatic amines are usually prepared by reducing nitro-compounds, nitrobenzene, for example, yielding aniline, $\text{C}_6\text{H}_5 \cdot \text{NH}_2$, in this way; intermediate reduction products, known as *azoxy*- and *azo*-compounds (*q.v.*), may also be prepared from aromatic nitro-compounds. Primary aromatic amines differ fundamentally from primary aliphatic amines in giving the impor-

tant diazo-reaction with nitrous acid (*see* DIAZO-COMPOUNDS). Moreover, whilst methylamine, dimethylamine and trimethylamine increase in basicity with the introduction of successive methyl groups, the opposite effect is observed upon introducing successive aromatic groups, such as the phenyl group, C_6H_5- . For instance, aniline (phenylamine), diphenylamine, $(C_6H_5)_2NH$, and triphenylamine, $(C_6H_5)_3N$, are in decreasing order of basicity, the last-named substance being insoluble even in strong mineral acids. Mixed aromatic-aliphatic amines, both secondary and tertiary, are more strongly basic than the pure aromatic amines, and less basic than the true aliphatic compounds; *e.g.*, aniline, $C_6H_5.NH_2$, monomethylaniline $C_6H_5.NH.CH_3$, and di-methylaniline, $C_6H_5.N(CH_3)_2$, are in increasing order of basicity. These observations may be summarized by saying that the benzene nucleus is more negative in character than the alkyl or other aliphatic radicals. In agreement with this conclusion, benzoic acid, $C_6H_5.COOH$, is a much stronger acid than acetic acid, $CH_3.COOH$.

As a general rule, homologues and mono-derivatives of benzene react more readily than the parent hydrocarbon with substituting agents; for example, phenol is converted into tribromophenol by the action of bromine water, and into nitrophenols by dilute nitric acid. Similar activity characterizes aniline. As already pointed out, not only does the substituent group modify the readiness with which the derivative is attacked, but it exerts also an orientating influence which determines the position of the further substitution.

Homologues of Benzene.—The following homologous formulae are obtained by the progressive addition of the usual increment, CH_2 , to the molecular formula for benzene. The isomerism here indicated may readily be deduced from the foregoing discussion:

C_6H_6 Benzene (b.p. $80.4^\circ C$).

C_7H_8 Toluene or methylbenzene (b.p. 110°).

C_8H_{10} Xylenes or dimethylbenzenes (3); ethylbenzene.

C_9H_{12} Trimethylbenzenes (3); methylethylbenzenes (3); propylbenzene; isopropylbenzene (cymene).

$C_{10}H_{14}$ Tetramethylbenzenes (3); *p*-methylisopropylbenzene (cymene); etc.

All four isomerides of the formula C_8H_{10} occur, like benzene and toluene, in coal-tar; *o*-, *m*- and *p*-xylene boil at 142° , 139° and 138° , respectively, and ethylbenzene at 136° . Mesitylene or *s*-trimethylbenzene (b.p. 165°), also occurs in coal-tar. Cymene (b.p. 175°) is found in the essential oils of various species of eucalyptus and other plants; hexahydrocymene (menthane or terpane), $C_{10}H_{20}$, is the parent compound of the majority of the terpenes (*q.v.*) and camphors (*q.v.*), and thus cymene is formed when ordinary camphor is dehydrated with phosphorus pentoxide and when pinene is heated with iodine. All these homologous hydrocarbons resemble benzene and toluene in their general character, and readily undergo nitration, sulphonation and halogenation.

Aromatic Radicals.—Among the aromatic radicals which occur commonly in the molecules of mononuclear aromatic compounds are the following: Phenyl, C_6H_5- , often abbreviated to Ph; benzoyl (Bz), $C_6H_5.CO-$; benzyl, $C_6H_5.CH_2-$; benzylidene or benzal, $C_6H_5.CH=$; phenylene, $-C_6H_4-$. Generically, aromatic radicals, or *aryl* radicals, are denoted by the symbol Ar, and *aliphatic* radicals by R. Mixed aromatic-aliphatic radicals, like benzyl, are sometimes called *alphyl* radicals.

Polycyclic Benzene Derivatives.—The ring-systems of polycyclic or multinuclear compounds may be either distinct or condensed; nuclei of the latter type possess one or more of the ring-atoms in common.

Distinct Nuclei.—The simplest compound of the first type is *diphenyl*, $C_6H_5.C_6H_5$, a crystalline hydrocarbon (m.p. $71^\circ C$) which may be prepared from sodium and iodobenzene in ether (Fittig's reaction). *Diphenylmethane* (m.p. 26°), $(C_6H_5)_2CH_2$, and *triphenylmethane* (m.p. 92°), $(C_6H_5)_3CH$, are formed when benzene interacts with methylene chloride and chloroform, respectively, in presence of aluminium chloride (Friedel and Crafts' reaction); *tetraphenylmethane*, $(C_6H_5)_4C$, also is known.

In attempting to prepare hexaphenylethane by treating triphenylbromomethane with finely divided silver in an atmosphere

of carbon dioxide, M. Gomberg (1900) obtained a substance which differed markedly from the hydrocarbons just mentioned and from hexamethylethane, $(CH_3)_3C.C(CH_3)_3$. It combined with iodine, forming triphenyliodomethane $(C_6H_5)_3CI$, and behaved generally as an unsaturated substance. It was eventually accepted as *triphenylmethyl*, $C(C_6H_5)_3$, in which the non-cyclic carbon atom is tervalent. The existence of this exceptional derivative has been ascribed to a "steric dissociation" of hexaphenylethane, the fourth valencies of the "ethane" carbon atoms undergoing a mechanical disengagement owing to the spatial requirements of their three bulky phenyl groups. A dynamic equilibrium of the following nature appears to be set up when the substance is dissolved in fused naphthalene: $2(C_6H_5)_3C \rightleftharpoons (C_6H_5)_3C.C(C_6H_5)_3$. Tridiphenylmethyl, $C(C_6H_5)_3$, and several similar compounds have also been prepared.

Condensed Nuclei.—The three important coal-tar hydrocarbons, naphthalene, anthracene and phenanthrene, have been assigned molecular structures which result from the fusion of benzene rings; although they are not homologues of benzene, they show the general aromatic behaviour characteristic of the benzene nucleus. The molecule of naphthalene, $C_{10}H_8$, is usually represented as consisting of two benzene rings having a pair of adjacent carbon atoms in common; while the molecular structures of the pair of isomeric hydrocarbons, anthracene and phenanthrene, $C_{14}H_{10}$, are formed from three benzene nuclei. The discussion will be confined in this place mainly to the structure of these compounds; further information concerning their properties, reactions and derivatives will be found under the individual headings.

Naphthalene occurs in coal-tar to the extent of about 5%, and is the most abundant of the important primaries. It is the parent compound of a large number of purely synthetic dyes, and also of synthetic indigotin. It was isolated from coal-tar by Kidd, in 1820, and its composition was established by Faraday, in 1826. In 1866, the year following the publication of Kekulé's theory of the benzene ring, E. Erlenmeyer, Sr., proposed for naphthalene a structure (I.) consisting of two "ortho-condensed" benzene nuclei, with two common carbon atoms. Since naphthalene yields *o*-phthalic acid upon oxidation, its molecule must contain at least one benzene ring; and according to Erlenmeyer's formula, either of the benzene rings (*a*) or (*b*), may undergo oxidative fission to yield this product:

Shortly after Erlenmeyer's suggestion had been made, Graebe established the symmetry of the naphthalene nucleus, and showed that whichever half of the molecule be oxidized *o*-phthalic acid results. Similarly, α -nitronaphthalene, $C_{10}H_7.NO_2$, formed by the action of strong nitric acid on the hydrocarbon, yields nitro-*o*-phthalic acid upon oxidation. The nitro-group, entering either of the rings (*a*) or (*b*), serves to distinguish that ring from the other; assuming the group to enter (*a*), it is obviously (*b*) which then undergoes disruptive oxidation. If, however, the nitro-group be reduced to the amino-group prior to this oxidation, the resulting α -naphthylamine, $C_{10}H_7.NH_2$, yields *o*-phthalic acid when oxidized; in this instance it is the second nucleus (*b*), distinguished by its non-substitution, which survives in the product. Thus the naphthalene molecule contains two potential benzene nuclei, having two adjacent carbon atoms in common:

The fundamental character of the naphthalene nucleus has been confirmed by a number of syntheses. Thus, the vapour of

phenylbutylene dibromide yields naphthalene when passed over lime at a faint red heat (Aronheim, 1873):

For all ordinary purposes it is sufficient to represent the naphthalene molecule by the double hexagon (II.); in order to facilitate nomenclature, the carbon atoms carrying hydrogen atoms are then numbered and lettered as shown below:

(II.) Abbreviated formula for naphthalene

Mono-substitution derivatives of naphthalene can thus exist in two isomeric modifications, depending upon whether or not substitution occurs on an atom adjacent to one of the two carbon atoms common to both rings: α -derivatives are produced by substitution in one of the equivalent positions, 1, 4, 5 or 8; β -derivatives by substitution in one of the second set of equivalent positions, 2, 3, 6 or 7. Orientation of such derivatives can often be accomplished by oxidation to the corresponding substituted *o*-phthalic acid. Substituted naphthalenes of the types C₁₀H₈X₂ and C₁₀H₆XY may exist in 10 and 14 isomeric modifications, respectively. If the two substituents are attached to adjacent carbon atoms in the same ring, the derivative bears a general chemical resemblance to ortho-disubstituted benzenes. Some of the characteristics of the latter compounds, particularly the ability to participate in further ring-closures, are shown also by the so-called *peri*-derivatives, which contain substituents in the 1, 8- or 4, 5-positions.

Since, as already indicated, Kekulé's formula affords an inadequate interpretation of the benzene molecule, it is not surprising that Erlenmeyer's derived formula fails to express the complete chemical behaviour of naphthalene. Indeed, the naphthalene molecule, like that of benzene, is probably capable of passing through a series of closely related structural phases. Erlenmeyer's formula explains the decompositions and syntheses of naphthalene derivatives, and accounts satisfactorily for the observed isomerism; but although naphthalene is more reactive than benzene, its chemical character is not in keeping with the presence of five double linkings in the molecule. According to Bamberger, the molecule is aromatic but not benzenoid; however, by the reduction of one ring, the other assumes a true benzenoid character. Thus, β -naphthol yields alicyclic tetrahydro- β -naphthol upon reduction; and this substance, in which the hydroxyl group is attached to the reduced ring, closely resembles the alcoholic 1- β -hydroxyethyl-2-ethylbenzene. Upon reducing α -naphthol, the hydrogen atoms enter the non-substituted ring, and the resulting aromatic tetrahydro- α -naphthol resembles the phenolic 1-hydroxy-2,3-diethylbenzene:

Analogous relationships hold for the corresponding amino-compounds.

In order to account for these peculiarities, formulae derived

from the centric hypothesis were advanced by Bamberger (III.) and Armstrong (IV.):

Bamberger's formula represents the molecule as containing a monocyclic nucleus of ten carbon atoms, which, however, is capable of facile transition into the *ortho*-condensed bicyclic system. When, as in the formation of naphthalene tetrachloride or 1, 2, 3, 4-tetrahydronaphthalene (tetralin), for example, the one ring becomes saturated, the other might be expected to assume the normal centric form and become truly benzenoid in character. This is so; thus, tetrahydronaphthalene has the character of an alkyl benzene, and α -tetrahydro- α -naphthol that of a phenol, as is shown in the diagram above. Bamberger's observations on reduced quinoline derivatives likewise point this out, that condensed nuclei of this type are not benzenoid, but possess an individual character; this disappears, however, when the molecule is reduced. Armstrong's formula (IV.) obviates the necessity of postulating the existence of a ten-membered ring, by assuming that one of the affinities of each of the two central carbon atoms common to the two rings acts into both rings. This assumption represents a deviation from the ordinary views of valency and affinity, but the symbol harmonizes with the fact that the two rings are in complete sympathy, the one responding to every change made in the other.

Other structural representations have been based upon Dewar's formula for benzene. Thiele's theory of partial valencies applies to the naphthalene molecule with a considerable degree of success. According to this theory, the molecule of naphthalene, unlike that of benzene, does not necessarily present a closed conjugated system. Thiele's formula (Va) indicates open partial valencies in two of the four *peri*-positions. The formula thus gives expression to the fact that naphthalene differs notably from benzene in the ease with which it forms additive compounds; moreover, the additive process sets in at the α -positions. Another phase of the molecule is possibly represented by an alternative formula (Vb), also based upon Thiele's theory:

When naphthalene is reduced with sodium in boiling alcoholic solution it yields 1, 4-dihydronaphthalene, a substance which possesses all the unsaturated characteristics of ethylene. This result is completely in accord with formula Va. The constitution of the dihydronaphthalene is shown by its oxidation to *o*-phenylenediacetic acid:

Further reduction yields 1, 2, 3, 4-tetrahydronaphthalene, and finally decahydronaphthalene (decalin, *q.v.*), C₁₀H₁₈, a fully saturated hydrocarbon, whose molecule contains two *ortho*-condensed cyclohexane rings.

As a rule, naphthalene yields mainly α -derivatives in substitution reactions; e.g., when it is chlorinated or nitrated; when it is sulphonated, however, the α -derivative predominates at 80°C and the β -derivative at 160°C . Substitution in the aromatic nucleus of 1, 2, 3, 4-tetrahydronaphthalene, on the contrary, furnishes a mixture of the α - and β -derivatives in which the latter often predominate. The derivatives of naphthalene resemble broadly those of benzene in their general behaviour. Thus, the naphthols exhibit the acidic character of phenols; the naphthylamines may be diazotized like aniline, etc.; and the naphthaquinones are very similar to the benzoquinones. Moreover, halogen atoms attached directly to the nucleus, although more reactive than in the benzene series, are stable towards hot aqueous alkalis.

Anthracene, $\text{C}_{14}\text{H}_{10}$, forms from about 0.25–0.45% of coal-tar. It is the basis of many artificial dyes and also of synthetic alizarin. According to Graebe and Liebermann's formula (I.), the anthracene molecule is composed of three ortho-condensed six-membered nuclei, the medial ring (which contains a para-linkage) being fatty in character, while the lateral rings are benzenoid. This formula represents adequately the syntheses, decompositions and general chemical behaviour of anthracene, but it should probably be regarded as one phase of a dynamic system which embraces formulae (II.) and (III.). The last of these is sometimes called the "ortho-quinonoid" formula. A centric formula also has been advanced by Bamberger.

According to Armstrong, one lateral ring is centric, while the remaining lateral ring and the medial ring are ethenoid. The fundamental nature of the anthracene nucleus is evident from the synthesis of dihydroanthracene; this compound, which results when *o*-bromobenzyl bromide is condensed in presence of sodium, may be oxidized to anthracene:

The abbreviated representation of anthracene, with the accepted numbering and lettering of the carbon atoms, is indicated below. These representations show that three isomeric monosubstitution compounds are possible, together with a considerable variety of disubstitution products:

When anthracene is reduced with sodium and alcohol, the medial ring is attacked with the formation of dihydroanthracene, mentioned above. Nitric acid attacks the molecule at the same points, yielding anthraquinone, the parent compound of alizarin and many other dyes.

Phenanthrene, $\text{C}_{14}\text{H}_{10}$, is an isomeride of anthracene. It is not oxidized so readily as anthracene, but with chromic acid it yields phenanthraquinone and then diphenic acid:

Both hydrogen (in presence of catalysts) and bromine yield additive compounds, namely, 9, 10-dihydrophenanthrene, $\text{C}_{14}\text{H}_{12}$, and phenanthrene 9, 10-dibromide, $\text{C}_{14}\text{H}_{10}\text{Br}_2$; the 9, 10-"bridge" is thus the most reactive grouping in the molecule. Phenanthrene has found no important technical application, but interest is lent to the substance through the occurrence of the phenanthrene nucleus in the molecules of certain opium alkaloids, (*q.v.*), including morphine.

The fraction of coal-tar boiling above 360° contains a number of still more complex hydrocarbons, including *pyrene*, $\text{C}_{16}\text{H}_{10}$, *chrysene*, $\text{C}_{18}\text{H}_{12}$, and *picene*, $\text{C}_{22}\text{H}_{14}$, the molecules of which are obtained structurally through the fusion of four, four and five benzene nuclei, respectively. *Retene*, or methylisopropylphenanthrene, $\text{C}_{18}\text{H}_{18}$, occurs in certain fossil resins. Condensed hydrocarbon nuclei which are partly aromatic in character result from the union of benzene rings with rings derived from cycloparaffins or cyclo-olefines; instances of such nuclei are provided by indene, hydrindene and fluorene (*vide infra*). From the large variety of hydrocarbons possessing nuclei which are wholly or partly aromatic in character, an immense number of derivatives may be obtained, since the hydrogen atoms may be substituted in the many ways which have been outlined.

Alicyclic Compounds, Monocyclic Derivatives.—As already pointed out, alicyclic compounds may be subdivided into cycloparaffins and cyclo-olefines and their derivatives. Substances of these types containing six carbon atoms in the nucleus are particularly important, and are sometimes classified under the separate heading of hydroaromatic compounds. In general, the cycloparaffins closely resemble the open-chain paraffins, while the cyclo-olefines are similar to the open-chain olefinic compounds.

The *cycloparaffins*, *polymethylenes* or *cyclanes*, are saturated cyclic hydrocarbons of the general formula C_nH_{2n} , or $(\text{CH}_2)_n$, in which n may be any integer from 3 to about 18. Theoretically, the first member of the series is ethylene, $\text{H}_2\text{C}=\text{CH}_2$, in which the double bond may be regarded as a two-membered ring. Cycloparaffins containing five or six atoms in the nucleus are sometimes called *naphthenes*. The simple cycloparaffins and their derivatives have no marked technical importance, although naphthenes are found in natural petroleum, particularly in the Caucasian variety. The terpenes and camphors, however, most of which are derived from *p*-methylisopropylcyclohexane (menthane or terpane), form a special group of outstanding importance, by reason of their abundant occurrence in essential oils and other natural products (*See TERPENES; CAMPHORS*). The formulae of some typical cycloparaffins are appended, the last three being naphthenes:

The unsaturated members of the series, or cyclo-olefines, are named on the Genevan system, in which the suffix, *-ane*, is replaced by *-ene*, *-diene*, *-triene*, etc., according to the number of double linkages, the position of the latter being indicated by the numerals following Baeyer's symbol, Δ . The compounds represented below may thus be termed, respectively, 1-methyl- $\Delta^{1:3}$ cyclohexadiene and $\Delta^{1:7}$ cyclooctadiene:

An alicyclic ring is often denoted by the prefix *ac*-.

It was long supposed that the simplest ring obtainable contained six atoms of carbon; so that the discovery by Freund, in 1882, of

cyclopropane aroused an interest which was enhanced by the novel chemical properties of the new hydrocarbon. With bromine, it combines less readily than the isomeric propylene, $\text{CH}_3\text{CH}:\text{CH}_2$, but it is easily converted by hydrogen bromide into *n*-propyl bromide, $\text{CH}_3\text{CH}_2\text{CH}_2\text{Br}$. The separation in this manner of carbon atoms united by single affinities was unprecedented at that time, but a similar behaviour has since been noticed in derivatives of cyclopropane, the ring being very susceptible to fission. Cyclobutane and its derivatives are rather more stable, and the nuclei containing five and six carbon atoms are very stable, showing little tendency to form open-chain compounds under ordinary conditions.

Baeyer has explained these variations in stability with considerable success by a purely mechanical hypothesis known as the "strain" or "*Spannungs*" theory (1885). Assuming the four valencies of the carbon atom to be directed from the centre of a regular tetrahedron towards its four corners, the angle between any two valencies is $109^\circ 28'$. According to the strain theory, the valencies undergo deflection in the formation of carbon rings, and the tension thus introduced may be deduced from a comparison of the tetrahedral angle with the new angle. The amount of the deflection is regarded as a measure of the reactivity, or instability, of the ring. Thus, the extraordinary reactivity of ethylene is attributed to the circumstance that the distortion is here a maximum, since, if deflected into parallelism, each valency will be drawn out of its original position through $54^\circ 44'$. The values in other cases are calculable from the formula $\frac{1}{2}(\alpha - 109^\circ 28')$, where α is the internal angle of the regular polygon contained by sides equal in number to the number of carbon atoms in the ring. The displacements for various polymethylenes are given below:

| Tri- | Tetra- | Penta- | Hexa- | Hepta- | Octa- |
|-----------------|----------------|----------------|----------------|----------------|-----------------|
| $-24^\circ 44'$ | $-9^\circ 44'$ | $-0^\circ 44'$ | $+5^\circ 16'$ | $+9^\circ 33'$ | $+12^\circ 46'$ |

The general behaviour of the several types of saturated homocyclic systems is certainly in accordance with this conception. It is found, for example, that the most stable of the above ring-systems are those containing five or six carbon atoms; a slight inward displacement is indicated for the five-membered ring and a somewhat larger outward displacement for the six-membered ring. It is, therefore, noteworthy that when benzene is reduced with hydriodic acid it is converted into a mixture of cyclohexane and methylcyclopentane; many other conversions of six-carbon rings into five-carbon rings have also been recorded. Similar considerations apply to heterocyclic rings; thus the γ -lactones, containing four carbon atoms and one oxygen atom in the ring, are more stable than the δ -lactones, which contain an additional carbon atom in the ring.

The strain hypothesis has been modified by J. F. Thorpe and C. K. Ingold. "It has, for instance, been calculated that whilst the natural inclination of two (carbon to carbon) valencies of a carbon atom carrying two hydrogen atoms is 115.3° , this inclination becomes depressed to 109.5° when the hydrogen atoms are replaced by groups such as methyl, which require a larger share of the space surrounding the carbon nucleus. This attachment of two methyl groups to carbon atoms involved in a 3-, 4-, or 5-membered ring considerably augments the stability of the structure, whilst if the ring contained six or seven carbon atoms a diminution in stability would result." (Thorpe, *Chemistry in the Twentieth Century*, London, 1924, p. 96.)

The limiting number of atoms which can be associated in a carbocyclic system by single valencies has not yet been determined. Large rings, containing up to about 30 carbon atoms, are difficult of access; but once formed they are just as stable as the C_6 - and C_8 -systems. This striking fact finds an explanation in the Sachse-Mohr theory of strainless rings, according to which the strain in large polymethylene rings may be relieved by a twisting into a multiplanar configuration. Thus, according to Mohr (1918), an indication of the existence of two strainless forms of the cyclohexane ring is to be found in the occurrence of two stable isomeric modifications of decahydronaphthalene, formed by the fusion of two such rings (*Annual Reports on the Progress of Chemistry*, 1926).

No isomerism occurs in the monosubstitution derivatives, but ordinary position isomerism exists in the di- and poly-substitution compounds. Stereoisomerism (*see STEREOCHEMISTRY*) also may occur, since the two atoms or groups attached to each saturated nuclear carbon atom are disposed, respectively, above and below the plane of the ring. The simplest examples are the dibasic acids: these yield a *cis*- (malenoid) form and a *trans*- (fumaroid) form. Such stereoisomerides may be depicted (Aschan) by representing the plane of the carbon atoms of the ring as a straight line. Thus, for the dicarboxylic acids ($\text{X}=\text{COOH}$) the possibilities are represented as follows:

The *trans*-compound, being usually asymmetric, is in such instances capable of existing in enantiomorphous forms, as indicated in the diagram. For example, *trans*-hexahydrophthalic acid, $\text{C}_6\text{H}_{10}(\text{COOH})_2$, has been resolved into dextro- and laevo-rotatory modifications; the *cis*-acid is symmetrical and unresolvable.

Hydrocarbons may be obtained from the dihalogen paraffins by the action of sodium or zinc dust, provided that the halogen atoms are not attached to the same or to adjacent carbon atoms (Freund, 1882; W. H. Perkin, Jr., 1888):

Tetramethylene dibromide.

Cyclobutane

They may be prepared also by the action of hydriodic acid on benzene hydrocarbons (*vide supra*); by passing the vapour of benzene hydrocarbons over finely divided nickel at 180 – 250°C (Sabatier and Senderens); from hydrazines of the type $\text{C}_n\text{H}_{2n-1}\text{NH.NH}_2$, by oxidation with alkaline potassium ferricyanide (Kijner); and from semicarbazones of the corresponding cyclic ketones, by reduction. Unsaturated hydrocarbons of the series may be prepared by the elimination of water or halogen acid from the corresponding alcohols or halogen derivatives. Pure cyclobutene has been made by distilling the quaternary ammonium hydroxide of aminocyclobutane.

The boiling points of successive cycloparaffins, from cyclopropane to cyclononane, are -35° , 11° , 49° , 81° , 117° , 146° and 171°C . The boiling points and specific gravities of these hydrocarbons are higher than the constants for the corresponding open-chain olefines or paraffins. Cyclohexane, C_6H_{12} , is an important constituent of Caucasian petroleum; it may be prepared by the catalytic hydrogenation of pure benzene. It is oxidized by nitric acid to adipic acid, and is converted by chlorine to monochlorocyclohexane; the latter derivative yields tetrahydrobenzene (b.p. 84°) when treated with alkalis. Aminocyclohexane is fundamentally similar to the primary hexylamines. Cyclopentadecane, $\text{C}_{15}\text{H}_{30}$, and cycloheptadecane, $\text{C}_{17}\text{H}_{34}$, prepared by reducing the semicarbazones of the corresponding cyclic ketones, melt at 61° and 65° , respectively.

Of the cyclo-olefines, cyclopentadiene, C_5H_8 (b.p. 41°), occurs in crude coal-tar benzene. Owing to the peculiar reactivity of its methylene group, this substance condenses readily with aldehydes and ketones, acetone, for example, yielding the intensely coloured hydrocarbon, dimethylfulvene:—

Cyclohexene or tetrahydrobenzene, C_6H_{10} , boils at 84° (*vide supra*), while $\Delta^{1:3}$ - and $\Delta^{1:4}$ -cyclohexadiene (the isomeric dihydrobenzenes, C_6H_8), boil at 81 – 82°C .

Cycloheptatriene (tropilidene), C_7H_8 , may be prepared from cycloheptanone; it is also a degradation product of cocaine and atropine (*see ALKALOIDS*). $\Delta^{1:7}$ -Cyclo-octadiene, C_8H_{12} , has been prepared from the alkaloid, ψ -pelletierine, by exhaustive methyla-

tion. Cyclo-octatetrene, C_8H_8 , is interesting by reason of the fact that it displays no aromatic characteristics, although the nucleus possesses a system of alternating single and double bonds; this evidence was adduced by Willstätter (1911) in favour of the centric constitution for benzene. Mention may also be made of C. Harries' unsubstantiated suggestion of a cyclo-octadiene ring as the possible structural basis of the molecule of caoutchouc, the hydrocarbon of rubber, whose properties show that its molecular structure is more complex than its empirical formula indicates.

Alcohols are obtained from the corresponding halogen compounds by the action of moist silver oxide or silver acetate and acetic acid; by the reduction of cyclic ketones with metallic sodium; by passing the vapours of monohydric phenols, in admixture with hydrogen, over finely divided nickel; by the reduction of cyclic esters with sodium and alcohol; and by the addition of the elements of water to unsaturated cyclic hydrocarbons, on boiling with dilute acids.

Cyclohexanol or hexahydrophenol, $C_6H_{11}OH$ (b.p. $160.5^\circ C$), is readily prepared by the catalytic hydrogenation of phenol in presence of finely divided nickel at $150^\circ C$. It reacts with hydrogen bromide to yield monobromocyclohexane (b.p. 162°), and undergoes dehydration to tetrahydrobenzene when heated with oxalic acid. Quinitol (cyclohexane-1:4-diol or hexahydroquinone) $C_6H_{10}(OH)_2$, results when cyclohexane-1:4-dione (*p*-diketohexamethylene) is reduced with sodium amalgam; it exists in *cis*- and *trans*-forms (m.p. 102° and 139°). Quercitol, or cyclohexanepentol, $C_6H_9(OH)_5$, occurs in acorns; it is optically active, forms colourless prisms (m.p. 234°), and has a sweet taste. Inositol, or cyclohexanehexol, $C_6H_8(OH)_6$, is widely distributed in plants and animals. Like the structurally isomeric hexoses, it has a sweet taste. Although it possesses no carbon atom which is asymmetric in the ordinary sense, it is capable of displaying optical activity in the amorphous condition. Anhydrous *d* (or *l*)-inositol melts at 246° , *dl*-inositol at 253° , and an internally compensated form at 225° .

The aldehydes, of which comparatively few have been studied in this series, are prepared in the usual manner from primary alcohols and acids: hexahydrobenzaldehyde, $C_6H_{11}CHO$, and hexahydro-*m*-toluic aldehyde, $CH_3 \cdot C_6H_{10}CHO$, boil at 159° and 176° , respectively.

The ketones are obtained by the dry distillation of the calcium salts of dibasic saturated aliphatic acids (Wislicenus, 1893), and by synthetic methods from malonic ester, acetoacetic ester, etc. (see ALIPHATIC section). The first method affords satisfactory yields of the saturated members up to cycloheptanone; and cyclo-octanone can be obtained in a similar way from thorium azelate in a yield of 25%. Owing to their accessibility, these ketones have been utilized largely in the preparation of other derivatives in this group. Cyclobutanone, $(CH_2)_4CO$, boils at 100° , and cyclopentanone, $(CH_2)_5CO$, at 129° . Cyclohexanone, or keto-hexamethylene, $(CH_2)_6CO$, is prepared by distilling calcium pimelate or by oxidizing cyclohexanol, to which it is readily reduced. It oxidizes to adipic acid, and may be acetylated, owing to its tautomeric relationship to Δ^1 -tetrahydrophenol. Cyclohexanone boils at 155° , and cycloheptanone (suberone) $(CH_2)_7CO$, at $180^\circ C$.

Apart from their existence in a few naturally occurring substances (*v. inf.*), alicyclic rings with from 10 to about 30 carbon atoms are accessible only by vacuum distillation of the thorium salts of the above-mentioned acids (Ruzicka, 1926). The resulting ketones, from cyclododecanone, $(CH_2)_{12}CO$, to cyclo-octadecanone $(CH_2)_{18}CO$, are solids, the melting-points of the successive members being 59° , 32° , 52° , 63° , 56° , 63° and $71^\circ C$. These ketones possess characteristic odours, and cyclopentadecanone ("exaltone"), $(CH_2)_{15}CO$, is used as a synthetic substitute for musk. Muscone, $C_{15}H_{30}O$, the main odoriferous constituent of natural musk, is a 2-methylcyclopentadecanone, and civetone of the civet cat is Δ^8 -cycloheptadecanone, $C_{17}H_{30}O$ (Ruzicka).

A great impetus was given the study of polymethylene derivatives by the important and unexpected observation made by W. H. Perkin, Jr., in 1883, that ethylene and trimethylene bromides are able to react with sodio-acetoacetic ester to form tri- and tetra-

Cyclopropanecarboxylic acid is a colourless oil. The truxillic acids, $C_8H_8O_4$, are polymerides of cinnamic acid, and they result in the hydrolysis of truxilline. Structurally, they are phenyl derivatives of cyclobutane. Derivatives of the cyclopentane group occur commonly as break-down products of the terpenes and camphors (*q.v.*); for example, campholic acid, obtained from ordinary camphor by hydrolysis, is 1,2,2,3-tetramethylcyclopentane-3-carboxylic acid. Hexahydrobenzoic acid, or cyclohexanecarboxylic acid, $C_6H_{11}COOH$ (m.p. $30^\circ C$), may be prepared by the vigorous reduction of benzoic acid, or by the action of carbon dioxide on cyclohexyl magnesium iodide (see GRIGNARD REAGENT). The naphthenic acids of Caucasian petroleum are probably homologues of this substance. *l*-Quinic acid, or hexahydro-tetrahydrobenzoic acid, $C_6H_7(OH)_4COOH$, m.p. 162° , is an important substance occurring in cinchona bark, coffee beans, sugar beet and many other plants. Discovered by Hofmann in cinchona bark, in 1790, it is a by-product in the manufacture of quinine, and is used in pharmacy. At $250^\circ C$, it yields the lactone, quinide, which on warming with baryta water furnishes optically inactive quinic acid. Three hexahydrophthalic acids, or cyclohexanedicarboxylic acids, $C_6H_{10}(COOH)_2$, are known, containing the carboxyl groups in the 1, 2-, 1, 3-, and 1, 4-positions, and each exists in *cis*- and *trans*-stereoisomeric forms. The reduced phthalic acids were submitted to a detailed examination by Baeyer in his prolonged researches (1887-92) on the constitution of benzene, and numerous acids of the kind are known. Thus, from *o*-phthalic acid (benzene-1, 2-dicarboxylic acid) alone, it has been possible to prepare two hexahydrophthalic acids, four tetrahydrophthalic acids and eleven dihydrophthalic acids.

Polycyclic Derivatives.—Alicyclic rings may enter into the formation of any of the general polycyclic types which have been indicated in discussing polycyclic benzene derivatives. Such rings may therefore be associated in various ways with other homocyclic rings, which may belong either to the alicyclic or the aromatic division; thus, in decahydronaphthalene and tetrahydronaphthalene (*vide supra*) an alicyclic ring has undergone ortho-condensation with a second alicyclic ring and an aromatic ring, respectively. Wholly alicyclic derivatives containing two or three condensed rings are very numerous in the series of terpenes and camphors and their derivatives (*q.v.*). It will suffice, therefore, in this place to consider a few typical polycyclic compounds of mixed aromatic-aliphatic type. Among the most important members of this group are indene, hydrindene and fluorene (*q.v.*):

Indene (b.p. $178^\circ C$) occurs in the "heavy oil" fraction of coal-tar, and has also been obtained synthetically. The molecule contains a benzene ring ortho-condensed with a cyclopentadiene ring. The methylene group, like that of cyclopentadiene itself (*vide supra*), is unusually reactive. Upon reduction, indene passes into hydrindene (b.p. 176°), the cyclopentadiene ring being thereby converted into a cyclopentene ring. Fluorene (m.p. 113°), also in coal-tar, has been synthesized by passing diphenylmethane through a red-hot tube. The molecule contains two benzene rings condensed with a cyclopentadiene ring. The methylene group, owing to its position between two unsaturated carbon atoms, possesses an enhanced

reactivity: thus, fluorene, like indene, furnishes a potassium derivative and undergoes condensation with aldehydes.

Spirocyclanes and their derivatives possess two alicyclic rings having only one carbon atom in common. Such compounds, although not of natural occurrence, are interesting stereochemically, since the two rings occupy two planes intersecting at right angles through the common carbon atom. A single example is afforded by spiroheptanedicarboxylic acid (Fecht, 1907):

BIBLIOGRAPHY.—J. Read, *Text Book of Organic Chemistry* (1926), gives a general account of the whole subject; B. T. Brooks, *The Non-Benzoid Hydrocarbons* (1922) alicyclic compounds. (J. Rd.)

HETEROCYCLIC DIVISION

The subject of heterocyclic compounds, comprising as it does a large group of substances occurring in nature (alkaloids, anthocyanins, uric acid, etc.), is one of fundamental importance not only from the chemist's point of view in particular, but from the more general aspect having as its object the correlation of physics and chemistry with animal and plant metabolism. The synthesis of an enormous number of heterocyclic compounds has been accomplished, and these are of importance: (a) because of their identity with or relation to natural products, (b) because of some theoretical significance as, for example, in showing the mechanism of a chemical reaction, and (c) because of some properties that make them valuable to humanity, such as drugs, dyes, etc.

Heterocyclic compounds are distinguished from homocyclic compounds in that they contain at least one atom other than carbon in the ring. Such atoms may be of a variety of elements, but in most cases are nitrogen, oxygen, sulphur or selenium.

Heterocyclic compounds, like the homocyclic, may also exist in the form of fused ring systems, either with homocyclic or with other heterocyclic nuclei. Moreover while the fusion of two benzene nuclei results in naphthalene, the fusion of a benzene and a pyridine nucleus may result in either quinoline (*q.v.*) or isoquinoline, and the fusion of two pyridine nuclei may result in several isomeric naphthyridines of which the 1:8-derivative has recently been synthesized.

Naphthalene

Quinoline

Isoquinoline

1:8-Naphthyridine

The heterocyclic compounds are conveniently classified in two distinctive groups: (1) Unsaturated systems which often display a high degree of stability and constitute a well characterized class exhibiting a close relationship to benzenoid types—generally referred to as aromatic in character. (2) Systems resulting from ring closure of aliphatic (straight-chain) compounds to which in their deportment they display a close analogy and into which they are in general convertible by comparatively mild treatment, *e.g.*, by hydrolysis.

Unsaturated Heterocyclic Compounds.—Unsaturated heterocyclic compounds often exhibit the characteristics of aromatic types, *i.e.*, they usually possess a high degree of stability toward heat, some of them readily withstanding a dull red heat; they are difficult to oxidize, and when oxidation does take place it is generally attended by complete destruction of the ring; furthermore, the action of the halogens seldom results in addition compounds as final products (although these may be formed as intermediates), substitution of hydrogen occurring when reaction takes place at all; the action of nitric and sulphuric acids is characteristic and results in the production of nitro-compounds and sulphonic acids respectively; the action of anhydrous aluminium chloride and an acid-chloride (reaction of Friedel and Crafts) frequently results in the formation of ketones; finally, such compounds are as a rule not easy to reduce, and when reduction occurs the products behave like aliphatic compounds.

Aromatic properties have not been observed in three-, four-, seven-, or eight-membered rings but are restricted to five- and six-membered nuclei. Until the discovery of cyclo-octatetrene by Richard Willstätter, it was generally assumed that the presence of a series of alternate single and double bonds in a ring resulted in mutual saturation, with the consequent appearance of the aromatic properties. On this theory various formulae were ascribed to the benzene ring which were equally applicable to heterocyclic nuclei. Among the more recent developments the theory of the aromatic sextet of electrons has gained considerable favour. This theory does not attempt to account for the double bonds, but assumes that the union of two members of the ring requires only one pair of electrons, so that there is a pair of electrons unaccounted for by each conventional double bond, making in all three pairs or a sextet. It is admitted that the reasons for the stability of this system are not clearly understood, but nevertheless the view is a convenient one and generally applicable to the entire class of compounds which exhibit the aromatic characteristics. In cyclo-octatetrene the four double bonds contribute more than the required sextet of electrons and the substance behaves like an unsaturated aliphatic compound. The same is true of cyclobutadiene (except that there is a deficit of two

Cyclo-octatetrene

Cyclobutadiene

Pyridine

electrons here), whereas in pyridine the conditions for the aromatic sextet are fulfilled. The extension of this hypothesis to the γ -pyrones, furanes and thiophens follows, since the oxygen atom in the former is no longer neutral but acquires basic properties, with consequent ability to form stable salts and hence to supply the needed two electrons for the aromatic sextet.

γ -Pyrone

Furan

Thiophen

Selenophen

The application of the above-mentioned hypothesis to the pyroles, isoxazoles, oxazoles, pyrazoles, glyoxalines, etc., follows readily when certain empirical rules are observed. It is only necessary (1) to attribute an electron pair to each double bond whether that be a C-C or a C-N union, and (2) to attribute an electron pair to any divalent element or group in the ring such as oxygen, sulphur, selenium, imino- ($\text{NH}=\text{}$), etc.

Pyrrole

Isoxazole

Oxazole

Pyrazole

Glyoxaline

To the six-membered nuclei the same rules are applicable. Six-membered heterocyclic compounds containing nitrogen may be considered as derived from benzene by substituting a nitrogen atom for a methine ($\text{CH}=\text{}$) group. No chemical reactions are known, however, whereby a nitrogen atom can be introduced into a benzene ring in this way.

Pyridazine

Pyrimidine

Pyrazine

Cyanidine

Properties of Unsaturated Heterocyclic Compounds.—The extent to which unsaturated heterocyclic compounds exhibit the properties of benzene and its derivatives varies considerably; thus naphthalene has lost, to some extent at least, the chemical properties of benzene, for example in being much easier to oxidize than the latter. Just as the introduction of substituents into benzene may so modify the chemical properties that the nucleus no longer responds to well-known reactions, so it is hardly to be expected that pyridine should nitrate in exactly the same way that benzene nitrates.

Five-membered Aromatic Nuclei (1).—Five-membered rings containing one hetero-atom naturally fall into two distinct groups: (i.) those containing nitrogen in the ring, and (ii.) those containing oxygen, sulphur or selenium. The members of the second group resemble each other very closely in the methods of their synthesis and in their chemical and physical properties.

Pyrrole and Its Derivatives.—Pyrrole does not occur as such in nature. It is a constituent of bone-oil and is obtained in large quantity, particularly in America, from the products of the destructive distillation of waste leather. Synthetically, it is obtainable (and this is true of its alkyl and aryl derivatives) by distilling succinimide (or substituted succinimides) with zinc dust, the latter acting as a reducing agent.

A rather remarkable reaction is the easy conversion of pyrrole into succindialdoxime by the action of hydroxylamine:

The imino-group is acidic, in that the hydrogen is readily replaceable by potassium with the formation of crystalline potassium pyrrole.

The compounds formed by the fusion of pyrrole with other nuclei occur to some extent in nature. Indole, together with skatole (β -methylindole), is found in the products of pancreatic fermentation of albumins and the two products are generally present in human faeces. Indole, though it possesses a very offensive odour, is found in jasmine and other flowers, and when judiciously blended frequently becomes an important constituent of synthetic perfumes.

Indole was first obtained by distilling indigotin (the chief constituent of natural indigo) with zinc dust. Among other syntheses of indole derivatives, that due to Emil Fischer (1886) is of wide application. In this method the phenylhydrazones of ketones, aldehydes or ketonic acids are heated with an acid (hydrochloric) or zinc chloride, when ammonia is eliminated.

The occurrence of tryptophane as a hydrolytic product of proteins deserves mention, whilst the closely related alkaloid, hypaphotrine

(the betaine of *N*-trimethyltryptophane) occurs in *Erythrina hypaphorus*.

Of the more complex pyrrole derivatives, carbazole, which occurs in crude anthracene, deserves special mention, because it is the parent substance of a large number of closely related compounds (e.g., dinaphthopyrrole) some of which have found application in the manufacture of dyes. An interesting variant of the

Fischer indole synthesis has been achieved by the use of cyclohexanone phenylhydrazone which yields tetrahydrocarbazole. The latter on mild oxidation with mercuric acetate forms carbazole. The natural alkaloids, rutaecarpine, harmine and harmaline belong to this class.

Furane and Its Derivatives.—Furane, the parent substance of this group, was first obtained in 1870 by distilling the barium salt of pyromucic acid. This reaction is analogous to the formation of benzene from benzoic acid. Pyromucic acid, like benzoic acid, may be brominated and nitrated.

Furfural, an important furane derivative both theoretically and commercially (being used in the manufacture of synthetic resins), is produced quantitatively when pentoses, like arabinose, are distilled with dilute acids. In its commercial manufacture, corn cobs, after the removal of grain, are distilled with dilute acid, and the aldehyde is found in the distillate. The methyl-pentoses (rhamnose, fucose, etc.) under similar treatment yield methyl furfural. Furfural manifests all the reactions of aromatic aldehydes (e.g., benzaldehyde), and this behaviour follows necessarily from the aromatic nature of the furane ring. On treatment with caustic potash it yields pyromucic acid and furfuryl alcohol (Cannizzaro reaction) and on treatment in alcoholic solution with potassium cyanide it yields furoin (benzoin transformation). Coumarone and diphenylene oxide are representatives of condensed nuclei containing the furane ring.

Thiophen and Its Derivatives.—Thiophen, a close analogue of furane, exhibits the greatest similarity to benzene. The four

hydrogen atoms are replaceable by other groups, thus yielding innumerable derivatives, all of which give an intense blue coloration—the indophenin reaction—when mixed with a little isatin and concentrated sulphuric acid. This reaction is given by all commercial samples of benzene, toluene, xylene, etc., and is due to small amounts of thiophen or the methylthiophens which are invariably present. Just as succinic acid (or its imide) may be transformed into pyrrole, so the distillation of a mixture of sodium succinate and phosphorus trisulphide yields considerable quantities of thiophen. Of the fused nuclei, thiophthen, benzothiophen and diphenylene sulphide may be mentioned. Selenophen, the selenium analogue of thiophen, is less well known, but has been definitely characterized by H. V. A. Briscoe and J. B. Peel (1928).

Five-membered Aromatic Nuclei (2).—There is a second series of five-membered heterocyclic compounds containing at least two hetero-atoms, which exhibit very marked aromatic properties. These compounds may be viewed as being derived from the foregoing five-membered heterocyclic compounds by the substitution of nitrogen atoms for methine ($\equiv\text{CH}$) groups, and are collectively known as the azoles. Their names are derived from that of the parent monoheterocyclic nucleus and from the number of nitrogen atoms introduced. Thus furane and pyrrole each yield two isomeric azoles which are called furazoles and pyrazoles respectively. Substitution of two methine groups results in furo-diazoles and pyrro-diazoles. Similarly there are thiazoles, thio-diazoles, thio-triazoles, etc. In general, the azoles are somewhat resistant to oxidation, and when they are fused with the benzene ring it is often the latter which undergoes oxidation first. Thus, oxidation of benziminazole with potassium permanganate gives in part glyoxalinedicarboxylic acid. Further the C-alkyl derivatives (derivatives formed by replacing a hydrogen atom

joined to carbon by an alkyl group) are frequently oxidized to carboxylic acids (3-methylpyrazole gives pyrazole-3-carboxylic acid). It frequently happens that the azoles are only known in the form of fused systems (generally with benzene) or in the form of reduced derivatives.

Pyrazoles.—The most convincing evidence of the aromatic nature of the pyrazole nucleus is the behaviour toward sulphuric and nitric acids, sulphonic acids and nitro-pyrazoles being formed respectively. The nitro-compounds are easily reduced to amino-pyrazoles which on treatment with nitrous acid yield remarkably stable diazonium salts. The latter resemble the benzenediazonium salts in their transformations, and may, for instance, be converted into azo dyes by treating them with anilines, phenols, etc. The fusion of a pyrazole and a benzene nucleus results in the so-called indazole. There is no single expression which serves to account for the various transformations of indazole, and at least three different formulae have been suggested at various times. It is convenient to assume that the different forms are mutually convertible into one another and that the environment or the mode of synthesis determines the type. The elusive character of

the double bond makes it all the more explicable that indazole is strongly aromatic in properties, and on the basis of the electron sextet theory there is every reason to believe that the hydrogen atoms are in a state of dynamic equilibrium, and the system only becomes fixed when the hydrogen atoms are replaced. The fact that amino-indazole forms a comparatively stable diazonium salt is in complete agreement with the aromatic nature of the nucleus.

Glyoxalines.—Glyoxaline was discovered by Debus in 1856 as a reaction product of ammonia and glyoxal. Since then a large number of derivatives has been prepared and the chemistry of the entire class has been exhaustively studied by F. L. Pyman and his collaborators. The derivatives of glyoxaline which have been found in nature are perhaps limited to histidine, a product of the hydrolytic fission of many proteins; ergothioneine, found in ergot and blood; and a series of alkaloids (e.g., pilocarpine) which occur in various species of *Pilocarpus*. The alkaloids are closely related to one another and differ only as regards the nature of the second ring.

Six-membered Heterocyclic Compounds (1).—The members of this class which contain only one hetero-atom are by far the most important, and of these the nitrogen derivatives deserve special mention. The latter are, for the sake of convenience, divided into (1) derivatives of pyridine, and (2) fused systems containing the pyridine nucleus.

The Pyridines.—Pyridine was discovered in 1851, and together with its homologues it occurs in bone-oil and coal-tar. Its properties and those of its derivatives are described in a special article (see PYRIDINE). The occurrence of pyridine derivatives, which do not contain other systems fused with the pyridine nucleus, is restricted to a relatively small number. Ricinine, occurring in the seeds of the castor-oil plant (*Ricinus communis*) is a derivative of α -pyridone; its constitution has been ascertained by its synthesis by Späth and Koller (1923). Another important pyridine derivative is nicotine (see ALKALOIDS).

The Pyrones.—The pyrones are six-membered cyclic compounds containing an oxygen atom in the ring, together with a carbonyl ($=\text{CO}$) group. There are two forms theoretically possible, the α -pyrones and the γ -pyrones.

In general, the pyrones have lost their aromatic characteristics to some extent, but are conveniently classified in this section. They are weak bases and the salts are readily hydrolysed by water. Though the pyrones contain a ketonic group, they do not react with the reagents (hydroxylamine, phenylhydrazine, etc.) which are used to characterize ketones and aldehydes. The halogens do not add themselves to the double bond but form substitution products. The action of ammonia, especially on pyronecarboxylic acids is noteworthy, for the oxygen atom is in many cases easily substituted with the formation of pyridones. In this way phenylcoumalin (present in coto bark) even with ammonium acetate gives α -phenylpyridone. This reaction throws some light on to the mechanism by which plants may arrive at a synthesis of cyclic nitrogen compounds. The pyrones are easily formed from certain aliphatic compounds which might occur in nature as intermediates, and the subsequent transformation of the pyrones into pyridine and fused pyridine derivatives is entirely within the bounds of possibility.

Malic acid is converted into coumalic acid by treatment with strong sulphuric acid and the former occurs very abundantly in

nature. Malic acid has furthermore been found associated with chelidonic acid in a large variety of plants and in particular in *Chelidonium majus* (Stransky, *Arch. Pharm.*, 1920, 258, 56). Finally, the easy conversion of $\text{HO}_2\text{C}-\text{CO}-\text{CH}_2-\text{CO}-\text{CO}_2\text{H}$, acetone-dioxalic acid, into chelidonic by loss of water, makes it not improbable that a similar reaction takes place in plants.

A series of alkaloids accompanies chelidonic acid in many plants and the presence of meconic acid in company with the opium alkaloids (*see* ALKALOIDS) is particularly significant. Ammonia and perhaps other bases are admittedly present in all plants at some stages of growth, and this, together with the pyrones, which are particularly abundant in some plants that elaborate alkaloids, may supply the needed starting products for the vital synthesis of pyridine bases. α -methyl- β -hydroxy- γ -pyrone (or maltol) occurs in the needles of pines and the bark of larches, and is also formed on roasting malt.

Six-membered Heterocyclic Compounds (2): Fused Nuclei.—The fused ring systems containing a heterocyclic nucleus are particularly abundant in nature. They are in many cases more readily accessible by synthetic means than those containing only one ring. This is accounted for by the fact that they are largely derived from ortho-disubstituted benzenes. The latter are available by a great diversity of methods. In many instances, too, it is possible to bring about a ring closure (in the ortho-position) of a benzene derivative having a suitable side chain. For example, aniline reacts with ethyl acetoacetate, $\text{CH}_3\text{CO}-\text{CH}_2-\text{CO}-\text{C}_2\text{H}_5$, forming first ethyl β -anilino-crotonate (1) which on treatment with sulphuric acid gives α -methyl- γ -hydroxyquinoline (2) and alcohol, thus:

Quinoline and Its Derivatives.—Quinoline occurs in bone-oil and coal-tar and results when any of a large number of alkaloids is distilled alone or with zinc dust. Its synthesis and properties, together with those of its simple derivatives, are described in the article QUINOLINE. In their synthesis of cusparine, Späth and Brunner (1924) condensed γ -methoxyquinaldine with piperonal, and the resulting piperonylidene derivative (1) was reduced catalytically with hydrogen in the presence of palladium yielding a product identical with cusparine (2), obtained from the natural

source (the bark of *Galipea cusparia*). The alkaloid galipine (3), which accompanies cusparine in *Galipea cusparia*, was synthesized by a similar series of reactions, except that veratraldehyde was substituted for piperonal in the condensation.

An interesting synthesis of β -chloroquinaldine is achieved by treating a mixture of α -methylindole with chloroform and sodium ethylate.

This reaction is applicable to pyrroles and indoles in general and results in pyridines and quinolines respectively. When methylene iodide is used instead of chloroform in this reaction the products are pyridines and quinolines free from halogen. Kynurenic acid is of importance because of its occurrence in the urine of dogs after the ingestion of meat. It is also formed in the transposition of tryptophane and has been prepared synthetically. When it is heated, it loses carbon dioxide and is converted into kynurine or γ -hydroxy-quinoline. Cinchoninic and quininic acids are mentioned because of their relation to cinchonine and quinine respectively.

Among the synthetic quinoline derivatives, α -phenyl-cinchonic acid deserves mention on account of its general use as an antineuralgic and as a remedy for gout. It is known in commerce under the name of atophane, and has been specially recommended in the form of its hydriodide. A large number of derivatives of atophane have been prepared with a view to improving its value as a drug. The chemistry of the alkaloids of Cinchona forms one of the most inspiring chapters of historical chemistry. It was in 1792 that Fourcroy first isolated quinine in an impure condition. In 1810, Dr. Gomes, a Spanish physician, obtained a crystalline substance which he called "Cinchonino" from cinchona bark. The basic properties of this material were brought to the notice of Pelletier and Caventou, who, inspired by the recent observation of Sertürner on the existence of "organic alkalies" in nature, undertook an investigation of "cinchonino" and succeeded in isolating two substances which they named quinine and cinchonine. Later, they isolated strychnine and brucine from the seeds of *nux vomica*. The chemistry of strychnine has formed the subject of almost incessant research since its discovery. Over 100 years have elapsed and although it contains only 21 carbon atoms in the molecule, its constitution is still in doubt, although some evidence points to the existence of a partly reduced quinoline nucleus.

More than 20 alkaloids have been isolated from the various species of cinchona and *Remijia* (natural order, *Rubiaceae*) but only cinchonine and especially quinine have found an extensive application in medicine. The antipyretic properties of cinchona bark have been suspected in Europe since 1639, but the drug did not come into general use until nearly thirty years later. Although neither cinchonine nor quinine has been synthesized, the painstaking work of Hesse, of Rabe, of Königs and their collaborators has left no room for doubt regarding the constitution of either base, together with that of a large number of associated alkaloids.

Cinchonine

Quinine

Large numbers of more complex quinolines have also been prepared. These are of the nature of fused systems containing quinoline condensed with benzene and pyridine nuclei. Acridine, phenanthridine and anthrapyridine represent quinolines fused with a benzene nucleus.

Acridine

Phenanthridine

Anthrapyridine

The melting-points of the condensed systems gradually rise as more nuclei are added. There appears to be no upper limit to the number of nuclei that can be condensed into one system. The products, however, become more difficult to work with on account of their sparing solubility and high melting-points.

Isoquinoline and Its Derivatives.—Structurally, isoquinoline differs from quinoline in the position that the nitrogen atom takes up in the hetero-ring. In the former the nitrogen member is

separated from the benzene nucleus by a methine group: the difference is shown by their formulae:

Quinoline

Papaverine

Isoquinoline

The Benzopyrones.—Three benzopyrones are known: α -benzopyrone or coumarin, iso- α -benzopyrone or isocoumarin, and γ -benzopyrone or chromone. They may be considered as representing the simplest fused systems derived from a benzene nucleus

Coumarin

Isocoumarin

Chromone

Flavone

and an α - or a γ -pyrone nucleus. Like the simple pyrones, they react readily with ammonia (especially the isocoumarins). The remarks relative to the synthesis of cyclic bases from pyrones, made when considering the latter, apply with equal consequences here. It is not at all uncommon to find benzopyrones and alkaloids in the same plant. The delphiniums contain alkaloids in abundance, and kaempferol and related flavonols have been isolated from a number of them. Many flavonols are dealt with in the article ANTHOCYANINS.

Flavonol

Kaempferol

The two glucosides, aesculin and daphnin, on mild hydrolysis yield glucose together with aesculetin and daphnetin respectively.

Aesculetin

Daphnetin

Umbelliferone

Umbelliferone occurs in the bark of *Daphne mezereum* and is obtained by distilling different resins, such as galbanum and asafoetida. No derivative of isocoumarin has been isolated from natural products.

The Dibenzo- γ -pyrones.—The simplest dibenzo- γ -pyrone, xanthone, is obtained synthetically by a number of methods. The

majority of naturally occurring yellow colouring matters are derived from the latter or from flavone, although xanthone has not

Xanthone

Euxanthone

Gentisin

been found in plants. Only two members of the xanthone group have been isolated from natural products.

Euxanthic acid is the chief organic constituent of Indian yellow or purree. The latter used to be made in Bengal from the urine of cows which had been fed on mango leaves, but the crude product had a disagreeable odour and is now replaced almost entirely by synthetic dyestuffs. When heated with dilute acids, euxanthic acid is decomposed into glycuronic acid, $C_6H_{10}O_7$, and euxanthone. It is interesting to note that when euxanthone is administered to dogs and to rabbits it is eliminated in the urine in the form of its combination with glucuronic acid, that is as euxanthic acid. Gentisin, the colouring matter of gentian root, is a methoxy-euxanthone.

Reduction of xanthone converts it by stages into xanthidrol and xanthene. The former contains the nucleus of a number of syn-

Xanthidrol.

Xanthene.

thetic dyes and indicators. Conspicuous amongst these is fluorescein, the substance obtained by heating a mixture of phthalic anhydride, resorcinol and zinc chloride. Fluorescein and allied products are characterized by the fact that on treatment with

Fluorescein.

Quinonoid form.

Succinein.

alkalis they yield coloured salts, displaying an intense fluorescence, which is attributed to the formation of the quinonoid form, stable only in alkaline media. Phthalic anhydride may be replaced by other anhydrides, and resorcinol by other phenols. The product from succinic anhydride and resorcinol is termed succinein. The latter, and particularly the phenyl-succineins, also display a series of colour changes, together with a fluorescence, dependent on the alkalinity of the medium.

Dihydro-pyran Group.—Though the dihydro-pyrans do not belong to the aromatic heterocyclic compounds, they are conveniently mentioned because of their close relation to the pyrans.

A history which treats of natural dyes would undoubtedly devote considerable space to those chapters dealing with logwood (*q.v.*), Brazilwood (*q.v.*), Pernambuco and Sappanwood (*see* BRAZILWOOD). The Brazilwood is the product of *Caesalpinia braziliensis*. The use of logwood dyes, the product of *Caesalpinia echinata*, was prohibited in England by act of parliament in the reign of Queen Elizabeth, because it was said to produce fugitive colours. The names of W. H. Perkin, Jr., and R. Robinson are intimately associated with the chemistry of Brazilwood and logwood, which contain respectively brazilin ($C_{16}H_{14}O_6$) and haematoxylin ($C_{16}H_{14}O_6$).

Brazilin.

Haematoxylin.

Six-membered Polyhetero-atomic Nuclei (1).—The six-membered nuclei containing two or more hetero-atoms may be regarded as derived from the six-membered nuclei containing one hetero-atom by substituting one or more methine ($\equiv CH$) groups by nitrogen atoms. No strictly aromatic nuclei containing other atoms than nitrogen are known to occur, although theoretically ring systems containing quadrivalent oxygen are possible. These would be analogous to the pyrans, but are only known in the reduced form corresponding to the dihydro- and tetrahydro-pyrans. The entire group is known as azines and the members are termed diazines, oxazines and thiazines, according to whether they are derived from pyridine, by the replacement of a methine group by nitrogen, by oxygen or by sulphur, respectively. Only those members which contain nitrogen atoms in the ring are of much importance. A few of these occur in nature and some are used as dyes. It may be mentioned, however, that some complex and valuable dyes are derived from systems containing sulphur in the ring. Morpholine (so called because it was at one time thought that a similar ring was present in morphine), phenoxazine, thiodiphenylamine, and dioxane may be mentioned as examples of a class of substances which contain six-membered rings with only one or no nitrogen atom.

Morpholine.

Phenoxazine.

Thiodiphenyl-amine.

Dioxane.

Reference has already been made to the diazines in connection with the general characteristics of aromatic nuclei. They have been synthesized in some abundance, but the systems containing only one nucleus are not known to occur naturally.

Six-membered Polyhetero-atomic Nuclei (2). Fused Systems.—The fusion of pyridazine with benzene may result in either cinnoline or phthalazine, depending upon the position of attachment of the benzene nucleus.

Cinnoline.

Phthalazine.

Pyridazine-4:5-dicarboxylic acid.

The hetero-rings in these systems are very stable to oxidation. Phthalazine on treatment with alkaline potassium permanganate yields pyridazine-4:5-dicarboxylic acid. Phthalylhydrazine is probably dihydroxy-phthalazine, the keto-form passing into the more stable enol-form (hydroxy-form):

Keto-form.

Enol-form.

Among the halogeno-cinnolines and phthalazines those containing the halogen attached to the hetero-nucleus display the same reactions that are characteristic of α - and γ -chloro-quinolines. The halogens are readily replaceable by hydroxyl, amino- and similar groups. The methyl groups in the methyl derivatives are characterized by the same reactivity that they show in quinaldine and lepidine.

In the pyrimidine series there is only one benzo-derivative possible, namely, quinazoline. Oxidation converts it into pyrimidine-4:5-dicarboxylic acid by rupture of the benzene nucleus. The

extended labours of Marston T. Bogert have placed on record a truly formidable number of quinazolines. It is remarkable, however, that this list does not include either 2-*n*-propyl- or 2-isopropyl-4-hydroxyquinazoline, one of which is considered as representing the constitution of vasicine, an alkaloid obtained by Ghose (1927), from *Adhatoda vatica*. This is the only quinazoline derivative so far isolated from natural products.

Attention may be directed to the natural occurrence of a group of reduced purine derivatives of which caffeine, which occurs in coffee and tea, represents a member. Purine (*q.v.*) is the name applied to the system formed by the fusion of a pyridazine and glyoxaline nucleus, and is of special interest because it is related to uric acid.

Quinoxaline is the only possible compound obtainable by fusion of a pyrazine and a benzene nucleus. Oxidation ruptures the ben-

zene nucleus and yields pyrazine- α : β -dicarboxylic acid. Quinoxalines are particularly easy to synthesize from ortho-phenylenediamines on the one hand and 1:2-diketonic compounds on the other. In many cases the reactions are complete even at low temperatures. The synthesis of quinoxaline from *o*-phenylenediamine (1) and glyoxal (2) is represented as follows:

The more complex derivatives of pyrazine and particularly of phenazine form an extensive class of dyestuffs which are of some importance from the technical standpoint. These include, among

others, the eurhodines, toluylene-red, the indulines, safranines, indazines, etc. (*see* DYES, SYNTHETIC). The indulines are among the longest known aniline dyestuffs, having been described in 1865 by Caro and Dale. Derivatives of the three theoretically possible triazines are known. Cyanuric chloride is probably trichloro-cyandine, while cyanuric acid is the corresponding hydroxy-deriva-

tive. Many cyanides polymerize (*see* POLYMERIZATION) to derivatives of cyanidines spontaneously or on treatment with sulphuric acid, etc. Some derivatives of α -triazine are known, but β -triazine is only known in the form of reduced benzo-derivatives, *e.g.*, benzazimide. Three tetrazines are theoretically possible, but only

on account of its high content of nitrogen and because of its purple colour. It is quite stable and may be readily sublimed. Heterocyclic systems containing more than four nitrogen atoms are unknown.

Aliphatic Heterocyclic Compounds.—The aliphatic heterocyclic compounds are so closely related to the corresponding straight-chain members that they are conveniently divided into a number of classes, each class being derived from a corresponding type of aliphatic compound by the elimination of a molecule of water, ammonia, etc. On this basis the heterocyclic compounds are conveniently divided into the following groups: (1) cyclic ethers and thio-ethers of glycols and thio-glycols; (2) cyclic alkylene-amines resulting from diamino-paraffins by loss of ammonia or from chloro-amino-paraffins by loss of hydrogen chloride; (3) the lactones and lactides—internal ethers of hydroxy-acids (*see* ACIDS); (4) lactams and betaines (*q.v.*)—internal anhydrides of amino-acids; (5) cyclic derivatives of dicarboxylic acids (anhydrides, imides, hydrazides, alkylene-esters); (6) dihydro-pyrroles and tetrahydro-pyridines derived from amino-aldehydes and amino-ketones by loss of water. In many cases hydrolysis by means of acids and alkalis converts such cyclic compounds into the substances from which they are derived, but there are important exceptions.

The ease with which heterocyclic compounds are formed varies largely with the number of atoms in the ring. In general three- and four-membered rings are difficult to prepare, and once prepared are easily ruptured. They often behave as unsaturated compounds with which they are isomeric. Compounds containing up to 16 atoms in the ring, including several hetero-atoms, have been reported, but in many cases considerable doubt exists as to the validity of the assigned formulae. It has been frequently observed that three, four, seven, eight and higher carbon rings are usually much more difficult to form than five- and six-membered rings. In order to offer an explanation for this fact A. von Baeyer was led to announce his celebrated "Strain Theory," which has been discussed in the *homocyclic* section, and which applies almost equally to heterocyclic compounds. Thus, in general, five-membered rings are the most stable, six-membered rings are nearly as stable, whilst seven- and four-membered rings are less so, and three-membered still less.

The Cyclic Ethers.—The ethylene oxides are the most important members of this class. Two methods of preparation, both depending upon olefines for their starting materials, are important. In one case hypochlorous acid is added to the double bond and

the resulting chlorohydrin is treated with alkali which removes hydrogen chloride:

In the second method the olefine is treated with benzoyl peroxide, the function of which is to supply one oxygen atom:

During the World War large quantities of ethylene chlorohydrin were used in the manufacture of mustard gas. It was then made by the combined action of moist chlorine on ethylene, the water and chlorine reacting potentially to give hypochlorous acid. On the cessation of hostilities, peace-time uses were sought for this product, and it was converted into ethylene oxide, which has found a number of technical applications, *e.g.*, as a solvent.

The ether linkage is easily ruptured by a great diversity of reagents. The hydrogen halides open the ring and the products are the halogenohydrins. Amines act similarly and the products are amino-ethanols, *e.g.*, with ammonia, α -aminoethanol, $\text{H}_2\text{N}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{OH}$, is formed. Some amino-ethanols find extensive application in the synthesis of local anaesthetics.

The action of Grignard reagents on ethylene oxide is a particularly useful means of adding two carbon atoms to a chain. When *n*-butyl magnesium bromide, $\text{C}_4\text{H}_9\text{MgBr}$, is treated with ethylene oxide, an addition compound is first formed, which on gentle heating changes to a product which yields *n*-hexyl alcohol on decomposition with water. This reaction is applied commercially in the synthesis of β -phenylethyl alcohol, $\text{C}_6\text{H}_5\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{OH}$, which finds some application in perfumery. Trimethylene oxide,

oxide, but the higher ring homologues behave like the straight-chain ethers. Cineol, a constituent of eucalyptus oil, is a complex cyclic ether (*see TERPENES*).

Cyclic Imines.—The methods available for the synthesis of cyclic imines are, in general, the same as those for preparing secondary aliphatic amines. Those members of this group containing three and four atoms in the ring are difficult to prepare and not well known. A three-membered ring consisting of two nitrogen atoms and one carbon atom is present in diazomethane (1) and diazoacetic ester (2). Diazomethane is extremely poisonous but is of considerable use as a methylating agent in neutral media.

Diazomethane and its derivatives have the remarkable property of adding themselves to olefine-carboxylic acids; with ethyl fumarate it yields ethyl pyrazolidine-4:5-dicarboxylate (3). The latter when heated loses nitrogen and passes into ethyl cyclopropane-1:2-dicarboxylate (4).

Closely related to the pyrazolines, which are dihydro-pyrazoles, are the pyrazolones, which comprise a group of drugs possessing antipyretic properties. The representative of this group which has found the greatest favour is antipyrine (*q.v.*). Many reduced systems corresponding to and derived from the aromatic nuclei already discussed are known. Except for the five- and six-membered rings containing only one nitrogen atom they are relatively unimportant.

The Pyrrolidines.—The importance of the systems represented by a ring of one nitrogen and four carbon atoms can scarcely

be appreciated. This system is present in haemoglobin, chlorophyll (*q.v.*) and haemocyanin, and all evidence points to the existence of a close relationship between these natural products. The chemist has, as it were, supplied proof of the kinship of plant and animal life. The present chemical evidence goes to show that the rings are present in their unsaturated state and therefore these vital products must be classified with the pyrroles. The existence of pyrrolidine derivatives in nature is not confined to a few representatives. It is possible that some proteins may contain a pyrrolidone system, because the glutamic acid formed in their hydrolysis easily passes into pyrrolidonecarboxylic acid.

Proline and 4-hydroxyproline are products of the hydrolysis of proteins. Stachydrine (found in *Stachys tuberosa*) and betonicine (found in *Betonica officinalis*) are the betaines of the dime-

thylammonium derivatives of proline and 4-hydroxyproline respec-

tively. Hygrine, together with a group of related alkaloids, occurs in some varieties of coca leaves, and it is isomeric with tropine, as may be seen from the formulae. Physostigmine, the principal alkaloid of the Calabar bean (from *Physostigma venenosum*) is the only representative, either synthetic or natural, of a compound containing two pyrrolidine rings and a benzene nucleus.

The Piperidines.—Nature appears to have a special predisposition for the elaboration of piperidines, which are to be re-

garded as reduced pyridines. Piperine (*q.v.*), the chief constituent of pepper, yields piperidine and piperic acid on heating with alkalis. Conversely, piperic acid chloride on treatment with piperidine yields piperine, showing that the latter is the piperide of piperic acid. Considerable interest attaches to the chemistry

Coniine

Pelletierine

of coniine, a constituent of common hemlock (*Conium maculatum*) and the first alkaloid to be synthesized. The toxic properties of hemlock juice were recognized by the ancient Greeks, for it is recorded that Socrates was compelled to take an extract of hemlock in order to pay the supreme penalty exacted by the State.

The root bark of pomegranate, *Punica granatum*, contains a mixture of alkaloids from which five individuals have been isolated. Pelletierine and three others are closely related to coniine. The fifth alkaloid, pseudo-pelletierine, is the best known of the group, and is closely related to the tropine alkaloids,

which include cocaine, tropococaine, benzoyl-ecgonine, etc. This group of alkaloids is characterized by the fact that hydrolysis by alkali resolves them into two parts, one an acid and the other a hydroxyamino-compound. Atropic acid, $C_6H_5-CH(CH_2OH)-CO_2H$ (from hyoscyamine), benzoic acid and cinnamic acid are among the acid constituents. The basic groups are somewhat restricted to tropine and ecgonine, but others of less frequent occurrence are known. The alkaloids can be regenerated from their hydrolytic products and are therefore to be regarded as esters of the acid in combination with the secondary hydroxyl group. Frequently the carboxyl group is esterified; thus cocaine is methyl benzoyl-ecgonine.

Cocaine

Quinuclidine

Closely related to piperidine is quinuclidine, which represents an unusual type of organic architecture present in the cinchona alkaloids. The synthesis of quinuclidine, which involved a considerable number of stages, must be regarded as a noteworthy achievement. The alkaloid, sparteine, occurring in *Cytisus scoparius*, is generally regarded as containing either one or two quinuclidine groups (*see* ALKALOIDS).

Lactams.—The lactams are cyclic amides of amino-acids, and are present in abundance in protein molecules. The synthesis of lactams from the oximes of cyclic ketones is interesting, and is a special case of the Beckmann transformation. Cyclopentanone-oxime on treatment with strong sulphuric acid gives α -piperidone.

Cyclopentanone-oxime

 α -Piperidone

Anhydrides and Imides.—Anhydrides of dibasic acids are readily formed when they contain either five or six atoms in the ring. A few seven-membered cyclic anhydrides are known and among these that of diphenic acid may be mentioned.

Diphenic anhydride

Phthalimide

Benzylphthalimide

The most important member of the cyclic imides is phthalimide, obtained by heating phthalic anhydride and ammonia. It forms a potassium derivative, which when heated with alkyl halides forms potassium halide and an alkyl-phthalimide, which on hydrolysis with acids yields phthalic acid and the corresponding alkylamine. This reaction is applicable to an infinite variety of alkyl halides and is due to the extended researches of Gabriel and his co-workers. The hydrolysis with acids is, however, difficult in some cases, and a recent communication has overcome this obstacle by the ingenious use of hydrazine hydrate, which, with an alkylphthalimide, yields the free amine and phthalylhydrazide. For example, benzylamine, $C_6H_5-CH_2-NH_2$, is readily formed by treating benzylphthalimide with hydrazine hydrate. Benzylphthalimide is obtained by heating potassium phthalimide with benzyl chloride, $C_6H_5-CH_2Cl$.

A number of heterocyclic compounds containing phosphorus, arsenic, antimony, bismuth, silicon, lead, mercury and tellurium in the ring have been prepared. They are frequently derived from the Grignard compounds of 1:4-dibromobutane or 1:5-dibromopentane. The latter on treatment with silicon tetrachloride or with the compound, $PbCl_2(C_2H_5)_2$, yields the two products (1) and (2) respectively.

PHYSICAL CHEMISTRY

Physical chemistry is concerned with the dependence of physical properties on the chemical nature of the different forms of matter and the changes which these undergo. In the description of these relations, a convenient basis of subdivision is afforded by the three states of aggregation—gaseous, liquid and solid.

THE GASEOUS STATE

General Characteristics.—Matter in the gaseous state is distinguished by its tendency to occupy all the space at its disposal. This tendency may be counteracted by external forces, and the fact that the earth's gaseous atmosphere is confined within definite limits is to be attributed to the circumstance that the gaseous molecules are under the influence of gravitational force. Gases are particularly susceptible to changes of pressure and of temperature.

In 1662 Robert Boyle showed that the volume occupied by a gas varies inversely as the pressure when the temperature is constant. When kept at constant pressure, a gas expands when heated and the expansion or relative change in volume was found by Joseph Louis Gay-Lussac and John Dalton (1802) to be proportional to the rise in temperature. If v and v_0 are the volumes occupied at $t^\circ C$ and $0^\circ C$, the relation between the volumes is given by $(v-v_0)/v_0=\alpha t$ in which α , the coefficient of expan-

sion, represents the expansion which takes place when the temperature is raised from 0°C to 1°C . The value of α is about $1/273$, and we may therefore write the previous equation in the form $v/v_0 = (273+t)/273$. At $t = -273^{\circ}\text{C}$ the volume of the gas will become zero provided that the relation is valid over this range. It is also apparent that if this singular temperature, which is indicated by the volume relations, is made the basis of a new temperature scale, such that $(t + 273)^{\circ}\text{C} = T^{\circ}$ and $0^{\circ}\text{C} = 273^{\circ}$ the above equation may be written $v/v_0 = T/273$ according to which the volume is proportional to the absolute temperature. When this is combined with $p v = p_0 v_0$ (Boyle's law) we obtain $p v/p_0 v_0 = T/273$ or $p v/T = p_0 v_0/273 = R$, where R is a constant. This relation is independent of the nature of the gas, and if the volume v refers to the molecular quantity, *i.e.*, the quantity represented by the molecular weight, the value of R is found to be the same for all gases. It is known as the gas constant.

Experiments made by Gay-Lussac (1808) showed further that the volumes of reacting gases and of their gaseous products can be expressed by simple numerical ratios. The interpretation of these simple volume ratios and of the identical behaviour of gases towards pressure and temperature is greatly facilitated by the hypothesis of Amedeo Avogadro (1811), according to which equal volumes of different gases at the same temperature and pressure contain the same number of elementary particles or molecules. The inability of chemists to distinguish between atoms and molecules was mainly responsible for the lukewarm reception which was accorded to this hypothesis, and its fundamental importance was not recognized until a clear distinction between these entities was made by S. Cannizzaro in 1858.

Kinetic Theory.—The behaviour of gases, which is summarized in the equation $p v = RT$, finds a simple interpretation in terms of the kinetic theory (*q.v.*). According to this, a gas is supposed to consist of a very large number of small particles which are moving about in all directions with high speeds. The paths of these particles are rectilinear until their direction of motion is changed by collision either with other particles or with the walls of the containing vessel. Collision involves no loss of energy since the particles are perfectly elastic. At any instant, the velocities of individual molecules vary between wide limits and the directions of motion are distributed in random fashion. At a given temperature and pressure, the average speed and the mean distance traversed between successive collisions varies with the nature of the gas. For oxygen, the mean free path at 0° and 760mm. is $1.0 \times 10^{-5}\text{cm.}$ and the average velocity is 461 metres per second.

Denoting the mass of the molecule by m and the mean value of the square of the velocity by u^2 , the average kinetic energy of the molecules is $\frac{1}{2} m u^2$, which is a measure of the temperature. On the assumption that the pressure of a gas is measured by the impact of the molecules on the walls of the containing vessel, it may be shown that the pressure is given by $p = m n u^2/3v$, where n is the number of molecules in volume v . Since the temperature is measured by the kinetic energy, it follows at once that the product $p v$ is directly proportional to the absolute temperature as expressed by the equation $p v = RT$ and has a constant value when the temperature is fixed, as required by Boyle's law. If for two different gases, the pressures, volumes and temperatures are the same, and the numbers, masses and mean square velocities are represented n_1, m_1, u_1^2 and n_2, m_2, u_2^2 respectively, then

$$p v = \frac{1}{3} n_1 m_1 u_1^2 = \frac{1}{3} n_2 m_2 u_2^2$$

and

$$\frac{1}{2} n_1 m_1 u_1^2 = \frac{1}{2} n_2 m_2 u_2^2$$

from which $n_1 = n_2$, as required by the Avogadro hypothesis. Since the mean square velocity is given by $u^2 = 3 p v / m n$, and the density of the gas by $d = m n / v$, we may write $u = \sqrt{3 p / d}$, according to which the average molecular velocities for different gases at the same temperature and pressure are inversely proportional to the square roots of the respective densities. For molecules of the same size the rates of diffusion should be proportional to the velocities, and the above result is accordingly in agreement with the results obtained by Thomas Graham (1832) in his experiments on gaseous diffusion. Ocular evidence of the molecular

movement postulated in the kinetic theory is afforded by the Brownian movement of microscopic particles suspended in a fluid medium. Such particles must have the same kinetic energy as the surrounding molecules and their visible motion is attributable to the unbalanced effects of molecular bombardment.

Gases at Higher Pressures.—Although the simple or ideal gas laws afford a moderately accurate description of the behav-

FIG. 1.—DIAGRAM OF CURVES SHOWING THE BEHAVIOUR OF ETHYLENE GAS

Product $p.v.$, where p =pressure and v =volume, of any gas diminishes first as p increases, passes through a minimum value, and increases at a constant rate

four of gases at low pressures, there are large discrepancies at higher pressures. The classical experiments of Amagat show that the product $p v$ diminishes at first as the pressure increases, passes through a minimum value and then increases at a constant rate. The general behaviour is shown by the isothermal $p v - p$ curves for ethylene in fig 1. The nature of these curves suggests the incidence of two disturbing factors, one of which tends to increase the compressibility of the gas and the other to reduce it. If the actually compressible space is represented by the intermolecular space, then $p v$ becomes $p(v-b)$ where b is the space occupied by the molecules. Furthermore, if there are attractive forces between the molecules, it may be expected that such forces will tend to reduce the velocity of the molecules which impinge on the boundary walls of the gaseous molecules, for the latter in their approach to the boundary will be subjected to a restraining force. The measured pressure, which is the equivalent of the actual impacts, should therefore be smaller than the intrinsic pressure, that is to say, the pressure which corresponds with the average velocity of the whole of the molecules in the gaseous system. To obtain the intrinsic pressure, the manometric pressure must therefore be increased by a term which takes account of the attractive force. According to Johannes Diderik van der Waals, this correction is proportional to the square of the pressure, or more precisely, inversely proportional to the square of the volume, and when the two correction factors are introduced, the equation $p v = RT$ becomes $(p + a/v^2)(v - b) = RT$, which is the van der Waals' equation. This affords an account of the actual behaviour of gases, as illustrated by the diagram. The constants a and b depend on the nature of the gas. Many alternative forms of such equations of condition have been suggested. The equation of Daniel Berthelot, which takes account of the variation of the attractive force with that of the temperature, is of the type $(p + a/v^2 T)(v - b) = RT$ and is of special value in the investigation of problems connected with gases at low pressures. By its use, it is possible to determine with great accuracy the

molecular volume and the coefficient of expansion of an ideal gas and from these to derive the values of the gas constant R and of the absolute zero of temperature on the gas thermometric scale.

If a perfect gas were allowed to expand without performing external work, there would be neither loss nor gain of heat and the temperature would remain constant. In other words, the internal energy of a perfect gas is independent of the volume which it occupies. When, however, the molecules attract one another, the expansion entails the performance of work against these forces; the internal energy of the gas diminishes and its temperature falls. In the absence of attractive forces, the finite volume occupied by the actual molecules will still have a small influence and it may be shown that this factor will produce a rise of temperature. The combined action of these two factors produces what is known as the Joule-Thomson effect. At ordinary temperatures, most gases are cooled, but hydrogen is heated. From this it may be inferred that the attractive forces between the hydrogen molecules are very small. At lower temperatures the attractive forces increase, and the cooling effect is also obtained with hydrogen when the temperature falls below -80°C . Other gases show a similar inversion, but the inversion temperatures are well above the ordinary temperatures. The Joule-Thomson effect finds practical application in the liquefaction of gases (*q.v.*) by the Hampson and Linde methods.

Heat Capacity of Gases.—The heat required to raise the temperature of a gas varies with the conditions. The molecular heat at constant pressure, C_p , is greater than that at constant volume, C_v , the difference being represented by the external work which has to be done when the volume increases. For a gas defined by $pV=RT$, the expansion per degree is v/T , and the work $p v/T=R$. In heat units, this is approximately 2 cal., and therefore $C_p-C_v=2$. Per gram-molecule the kinetic energy of the gas is $E=\frac{1}{2}Nmu^2$, where N is the Avogadro number, and the increment of kinetic energy for one degree rise in temperature is $E/T=Nmu^2/2T=3pv/2T=3R/2=3.0$ cal. This value should be independent of the temperature and of the nature of the gas. It represents the smallest possible value of C_v and corresponds with $C_p=5.0$ and $\gamma=C_p/C_v=5/3$. Actual measurements made with monatomic gases are in good agreement with these theoretical deductions. Within the limits of error the value of C_v for helium is 3.0 over the range -250°C to $2,350^{\circ}\text{C}$, and measurements of the velocity of sound indicate that the value of γ for the monatomic inert gases, mercury vapour and the alkali metal vapours is $5/3$.

For gases which contain more than one atom in the molecule, the observed values of C_v and C_p are not only much larger, but they increase with the temperature. For water vapour the value of C_p is given by $C_p=8.81+0.0019T+0.0000222T^2$. The molecular heat ratio for polyatomic gases is less than $5/3$ and in general it diminishes with increase in the number of atoms in the molecule, as is indicated by the values for oxygen 1.40, ammonia 1.33, chloroform 1.15, ethyl alcohol 1.11 and ethyl ether 1.03. The ratio depends on other factors, however, as may be seen from the numbers for CH_4 1.31, CH_3Cl 1.28, CH_2Cl_2 1.22, CHCl_3 1.15, CCl_4 1.13, all of which contain five atoms in the molecule. It would seem that the kinetic energy of a monatomic molecule, the mass of which is concentrated in a tiny nucleus, cannot have any other form than that which is associated with its translatory movements. This kinetic energy corresponds, therefore, with three independent modes of motion or degrees of freedom in three directions at right angles to one another. In accordance with the Maxwell-Boltzmann principle of equipartition (*see* KINETIC THEORY OF MATTER) the energy quantity $C_v=3.0$ should be equally divided between these, and it follows that each degree of freedom is associated with a heat capacity approximately equal to one calorie.

In diatomic molecules, there are two mass centres relatively widely separated and such systems suggest the possibility of other degrees of freedom associated with intra-molecular movements, vibratory in type, of the atoms within the molecule, and with rotational or precessional motion of the molecule as a whole. At very low temperatures, the comparatively feeble impacts between the slowly moving molecules may not be sufficient to give rise to

such movements, and in this connection it may be noted that the value of C_v for hydrogen at low temperatures is three calories per degree. At these temperatures diatomic hydrogen would therefore seem to behave as a monatomic molecule. In general, the observed variation of the heat capacities of polyatomic gases with the temperature is, however, difficult to reconcile with the equipartition theory if all the molecules are supposed to have the same number of degrees of freedom. It would seem necessary to assume that those collisions for which the impact exceeds a certain critical value give rise to additional degrees of freedom. The total energy of the gas will then be the sum of the energies of that fraction for which the impacts are less than the critical value and of the fraction for which the impacts are greater than this.

An alternative basis of explanation is afforded by the quantum theory (*q.v.*). According to this, the exchange of energy between matter and space is a discontinuous process, radiant energy being absorbed by material systems in the form of discrete units or quanta, the magnitude of which is determined by the frequency ν as expressed by the equation $\epsilon=h\nu$ where h is a universal constant. The frequency of the absorbable radiation depends on the elastic constants of the molecules, and by the application of statistical considerations, the total energy absorbed by a material system at a given temperature and its dependence on the temperature may be calculated. The quanta associated with the translational movements of the molecules are very small, and for these the process of energy exchange is practically continuous and therefore in accord with the equipartition theory. As the temperature increases, larger quanta become available, and in the form of energy of the appropriate frequency such quanta are absorbed by the gaseous molecules in accordance with the statistical formula. In this way it appears to be possible to account for the observed facts.

Viscosity and Conductivity.—There are certain properties of gases, *e.g.*, the viscosity and thermal conductivity, which depend on the mean free path which is inversely proportional to the chance of collision. The viscosity or internal friction is a measure of the inherent tendency towards the equalization of the velocities of portions of gas which are moving relatively to one another. It may be shown that the viscosity η is given by $\eta=\frac{1}{3}dlu$, where d is the density, l the mean free path, and u the average velocity of the molecules. If, at constant temperature, the density is doubled, the mean free path will be halved, and it follows that the viscosity is independent of the pressure. If the temperature is raised at constant volume, it would appear that the viscosity should increase in proportion to the square root of the absolute temperature. The actual increase is greater and the discrepancy is in part attributable to the circumstance that at lower temperatures and smaller velocities the molecules are more likely to be deviated from their rectilinear paths by the action of the attractive forces between the molecules. Since the viscosity depends on the chance of collision, *i.e.*, on the total effective cross-sectional area of the molecules, it is obvious that viscosity data for different gases afford a means for the comparison of the respective molecular diameters.

At the ordinary pressure, gases are normally very good electrical insulators, although well-marked conducting qualities are acquired at very low pressures. Conducting properties may be induced by the action of X-rays, cathode rays, α - or β -particles, light of very short wave-length, or by certain chemical reactions in all of which processes the molecules are converted into ions by the loss or gain of electrons. As a result of the neutralization of the oppositely charged entities, the conducting properties tend to disappear when the ionizing agency is removed. If a difference of potential is created between two parallel plates in an atmosphere of ionized gas, the ions are directed to the plates. If the potential gradient is small, some of the ions may have their charges neutralized before they reach the electrodes, but the number of these diminishes with increase in the potential difference and ultimately all the charged particles reach the electrodes and the current reaches a maximum value. Further increase in the potential difference is without effect on this saturation current until the gradient becomes very much larger, when the current

begins to increase once more, at first slowly, and then more rapidly, until finally spark discharge occurs. Under these conditions, the movement of the electrons under the influence of the applied field is so rapid that ions may be produced by collision with the molecules of the gas. The minimum potential gradient required for this is termed the ionizing potential. The value of this for a particular gas depends on the precise nature of the electron-expelling process. Even when the velocity of the electron is insufficient to ionize the molecules of a gas, it may be able to displace an electron from one orbit to another. The characteristic potential in this case is known as the resonance potential. Such electron displacements are accompanied by the emission of light of characteristic wave-length and the effects in general can be interpreted in terms of the electron theory of atomic structure.

THE LIQUID STATE

If the temperature of a gas is below a certain limiting value and the pressure is gradually increased, the gas condenses to a liquid. This process involves a discontinuity in the relation between the pressure and the volume. On a p - v diagram, the condensation is represented by a horizontal line for which the pressure value corresponds with the vapour pressure of the liquid. The length of the condensation line diminishes with rise of temperature until the end-points coincide. This temperature is the highest at which a gas can be converted into a liquid and is called the critical temperature. The liquid state is non-existent above this limit. The recognition of the critical temperature is due to Thomas Andrews, who showed that this permits of the transition from the gaseous to the liquid state being carried out in a continuous manner. From the theoretical standpoint this is very significant, for it may be inferred that the essential features of the kinetic theory of the gaseous state may be directly applied to liquids. Since the van der Waals and other similar equations, which express generally the behaviour of gases, are derived on the implicit assumption of homogeneity of the system, it is obvious that they cannot be applicable to the ordinary condensation process. The theoretical isothermal curves must necessarily be continuous, and for temperatures at which condensation occurs in practice, the van der Waals equation yields a continuous curve with a maximum and a minimum pressure value (fig. 2). These become less pronounced as the temperature rises, and ultimately vanish. The temperature at which this occurs corresponds with that at which the three roots of the van der Waals equation, which may be shown to be a cubic in v , become equal to one another. This temperature corresponds, in other words, with the critical temperature, and in various ways it may be shown that the critical data are directly connected with the attraction and volume constants in the equation of condition. The relations in question are given by $v_c = 3b$, $p_c = a/27b^2$ and $T_c = 8a/27bR$. If a and b are known, these equations may be used to derive the critical constants; conversely, if the latter are known the constants a and b may be calculated. In terms of the equation of conditions, the characteristic feature of the liquid state is to be found in the very large magnitude of the pressure (internal pressure) which corresponds with the attractive force term a/v^2 and also in the very small difference between v and b . The kinetic condition of the molecules is nevertheless of the same kind, and the mean kinetic energy of the molecules has the same value as that of a gas at the same temperature. Properties which depend on the close association of the molecules attain to greater significance, however, in the liquid state.

In view of the large magnitude and the specific character of the attractive forces in liquids and the absence of any relation which might be supposed to be analogous to the Avogadro hypothesis, it will be readily understood that the comparison of the physical

properties of different liquids is attended by particular difficulties. The correlation of the physical properties of liquids with their composition and chemical constitution represented, nevertheless, one of the most important branches of physical chemistry in its earlier stages of development. It was suspected that the relations in question might possibly be made the basis of methods which could be used to supplement the information provided by the more specifically chemical methods followed in the attempts to determine the structure of chemical compounds. The work done in this connection has been largely empirical and fundamental questions incidental to the problem have not received that amount of consideration to which they are justly entitled.

Comparison of Physical Properties.—The study of a particular physical property for such purposes involves two primary considerations. The first relates to the method of measuring the property and the second is concerned with the conditions under which the comparison is made. These points may be illustrated by reference to the property which is commonly measured by the density or mass of unit volume. The same property may be measured in terms of the specific volume, or volume of unit mass. Both density and specific volume are indeed measures of what may be termed the space-filling capacity of matter. They are reciprocally connected with one another, and it is obvious that the relations shown by a comparison of densities will be very different from those which are indicated by a comparison of specific volumes. Since $d = m/v$ and $\phi = v/m$ and the mass (m) is independent of temperature and pressure, whilst the volume (v) is a function of both, there are obvious reasons for the choice of specific volume rather than density as a measure of space-filling capacity. Since, further, chemically comparable quantities are not those represented by equal masses, but by masses which are in the ratio of the molecular weights, the volumes which should be compared are not the specific volumes, but the molecular volumes defined as $V_m = m\phi$. If molecular volume is accepted as a suitable measure of space-filling capacity, there still remains the question of comparable conditions. In view of the slight compressibility of liquids, the influence of temperature only need be considered. In his classical researches Hermann Kopp decided this matter empirically by comparing the molecular volumes of liquids (1) at the same temperature; (2) at the respective boiling-points of the liquids. The result was to show that simple relations are more clearly evident when the boiling-point data are compared. Kopp's choice was subsequently justified by theoretical developments which culminated in the theory of corresponding states.

Considerations such as have been illustrated by reference to space-filling capacity constitute a preliminary step in the comparative study of all physical properties. For instance, internal friction may be measured in terms of viscosity or fluidity, electrical conducting power in terms of conductivity or resistivity and the discovery of the connection between such properties and the chemical nature of substances is obviously dependent on the choice of the basis of comparison. Not infrequently, the selection involves the consideration of alternative measures which are not merely reciprocal, but bear a much more complex relation to one another. Ideal measures would in fact be those which are entirely independent of external circumstances, temperature, pressure, and even state of aggregation, but apart from mass, the physical properties of matter are not of this ideal nature and the problem of correlation is attended by many difficulties. In so far as the attainment of comparable temperatures is concerned, a finger-post would seem to be provided by the theory of corresponding states. The origin of this is to be found in the circumstance that the ordinary equations of condition with specific constants may be reduced to a general form from which the specific constants have been eliminated. The conversion is effected by measuring for each substance the pressure, volume and temperature in terms of the corresponding critical values, such that $\pi = p/p_c$, $\phi = v/v_c$ and $\theta = T/T_c$. In these circumstances the van der Waals equation reduces to $(\pi + 3/\phi^2)(\phi - \frac{1}{3}) = 8\theta/3$ which contains no specific constants and represents, therefore, and is an equation which should be applicable to all substances, independently of their chemical nature. The reduced form of the

FIG. 2.—MODEL SHOWING BEHAVIOUR OF A GAS AND ITS CONDENSATION BELOW ITS CRITICAL POINT

Pressure, volume and temperature are correlated by Van der Waals's equation

equation is the same in type as the original and it may be shown that other equations of condition may be generalized in the same way, provided that these afford an account of the critical state and contain three constants; *i.e.*, the same number of constants as variables. Substances for which the values of π , ϕ and θ are identical are said to be in corresponding states, and the general reduced equation is the analytical expression of the theory of corresponding states, according to which comparable temperatures are provided by equal values of θ . Although the experimental data of Sydney Young show that the above reduced equation is by no means an exact expression of the relation between corresponding states, yet the deviations are such as to suggest that the fundamental idea involved in the theory is substantially correct. From this, however, it does not follow that correspondence in respect of pressure, volume and temperature provides the conditions for correspondence in other properties; any such assumption is necessarily of a tentative character.

In actual practice, the comparison of physical properties has been for the most part made at a fixed temperature. In such circumstances the actual conditions are frequently far removed from those indicated by the theory of corresponding states. The results obtained show that many properties when referred to molecular quantities of the different substances can be represented as the sum of a series of terms which depend on the nature of the constituent atoms and also on the manner in which the atoms are linked together within the molecule. In other words, there is evidence of additivity modified by the incidence of structural factors. At one time the principle of additivity was sought to be maintained by the assumption that the values assigned to certain atoms vary with their mode of combination. More recently the constitutive influence has been taken into account by the hypothesis that the structural peculiarities make a direct contribution to the observed value of the property in the same way as the atoms themselves. In accordance with this view the molecular value of a property of a compound $C_xH_yO_z$ can be expressed by the relation $P = xP_C + yP_H + zP_O + \sum P_s$ in which P_C , P_H and P_O are the atomic values of the property for carbon, hydrogen and oxygen, and $\sum P_s$ is the sum of corresponding terms for the constitutional factors.

Volume Relations.—Kopp's measurements of the molecular volume $V_m = m/d$ of substances at their respective boiling-points showed that a given change in molecular composition is accompanied by a fairly constant change in the molecular volume. In ascending homologous series (*see* CHEMISTRY: Organic: Aliphatic Division) the change produced by the substitution of the methyl group for the hydrogen atom is on the average about 22 cu.cm., which is taken to represent the volume of the group CH_3 . The volume increments for CH_2 vary from 20.5 in the amine series to 24.4 in the ester series. In spite of this variability and of many similar inconsistencies, Kopp came to the conclusion that the molecular volume is essentially additive in nature and can be represented as the sum of the atomic volumes of the constituent atoms provided that the values allocated to certain atoms are assumed to depend on their mode of combination. The values assigned to the different elements are illustrated by the series: C=11, H=5.5, Cl=22.8, Br=27.8, I=37.5, S=22.6, O (singly linked)=7.8, O (doubly linked)=12.2. In the case of nitrogen, the value appeared to vary so largely with its mode of combination that many chemists hesitated to apply Kopp's system to compounds containing nitrogen. Subsequent investigations, in which particular attention was given to isomeric compounds, showed clearly that the idea of constant atomic volumes is not in harmony with the facts. Constitutive effects are clearly shown when isomeric compounds are compared, and in general the largest differences are found when the isomerides compared belong to different chemical groups, whilst the smallest are associated with isomerism of the position type.

Kopp's derivation of the atomic volumes of carbon and hydrogen is based on the comparison of the molecular volumes of aliphatic compounds, *e.g.*, C_4H_{10} , with those of benzene compounds, *e.g.*, C_6H_6 , in which an increase of two in the number of carbon atoms is offset by a diminution of four in the number of hydrogen atoms. Such pairs of compounds have very nearly the

same molecular volume, and from this observation it was inferred that the volume of the carbon atom is twice as great as the volume of the hydrogen atom. Since $CH_2=22$, it follows that $C=11$ and $H=5.5$. The derivation of these values obviously ignores the influence of ring formation on the molecular volume. More recently, a system of atomic volumes has been evolved by G. Le Bas, which is based on a comparison of aliphatic compounds with the corresponding olefines. In this, which yields $C=14.7$, $H=3.7$, no account is taken of the influence of the double bond. The relations are nevertheless very similar to those which are exhibited by the older system.

Although the use of the boiling-points for the comparison of the molecular volumes of liquids provides a temperature basis which is theoretically justified in so far as the boiling-points are approximately equally reduced temperatures, it should be recognized that the internal pressures resulting from the attractive forces between the molecules are not generally comparable under these conditions. In this connection, attention may be directed to a new method proposed by S. Sugden, in which the influences of temperature and of pressure are eliminated. In this it is assumed that a measure of the magnitude of the internal pressure is afforded by the surface tension. The development of the actual procedure is based on the observation that the connection between the surface tension (γ) of a liquid, the density (D), and the density (d) of its saturated vapour can be expressed very exactly by the relation $\gamma = C(D-d)^2$, in which C is independent of the temperature. If $C^{1/4}$ is multiplied by the molecular weight, a quantity P is obtained, the value of which may be derived from $P = M\gamma^{1/4}/(D-d)$. This is termed the "parachor," and since $M/(D-d)$ at low temperatures, where d is very small in comparison with D , represents the molecular volume of the liquid, it is obvious that the parachor affords a comparison of molecular volumes under conditions in which the surface tensions and therefore the internal pressures of the different liquids have the same value. In support of the view that the parachor really affords a measure of the volumes occupied by the actual molecules, it is found that this quantity bears a nearly constant ratio to the critical volume as expressed by $P=0.78 V_c$.

For saturated substances the parachor can be expressed additively in terms of atomic constants. These appear to be independent of the mode of combination of the atom and position isomerism is without effect. Unsaturation and ring formation produce notable changes and these vary but slightly from compound to compound. A double bond between two carbon atoms produces the same effect as the double bond between carbon and oxygen, or between nitrogen and oxygen in the nitroxyl group. The same structural constant can be used for the six-membered rings of benzene, cyclo-hexane, pyridine, piperidine and quinoline. The two oxygen atoms in the carboxyl group would, however, seem to require a special constant. The accompanying table shows the values of various atomic and structural parachors:

| Atomic and Structural Parachors | | | | |
|---------------------------------|------|----|------|-------------|
| C | 4.8 | F | 25.7 | = 46.6 |
| H | 17.1 | Cl | 54.3 | 3-ring 22.5 |
| O | 20.0 | Br | 68.0 | 4- " 12.0 |
| O ₂ (ester) | 60.0 | I | 91.0 | 5- " 8.5 |
| N | 12.5 | = | 23.2 | 6- " 6.1 |

The results obtained in the study of the parachor are such as to suggest that this may be of real value in the elucidation of many of the structural problems which are presented by organic chemistry.

In the belief that many of the irregularities associated with molecular volumes are due to polymerization (*q.v.*) or the formation of molecular aggregates, J. Traube instituted a comparison of the volumes occupied by substances when dissolved in water or other solvent to form dilute solutions. The derivation of the molecular solution volumes at 25° C involves the assumption that the volume occupied by the solvent is not affected by the presence of the dissolved substance. This is certainly not justified, but it is nevertheless noteworthy that the volume relations exhibited by this system are very similar to those which are found by the comparison of substances in pure liquid condition at the respective boiling-points. The fact that the sum-

mation of the atomic and structural constants leads to values of the molecular volume which are less than the actually measured volume by a constant quantity (12.6 cu.cm. in water at 25° C) suggests that this may be connected with the contraction of the solvent.

Volatility of Liquids.—The term volatility refers to the tendency of a substance to pass into the state of vapour. At a given temperature this may be measured by the vapour pressure, and at a given pressure by the corresponding boiling-point. Many empirical formulae have been put forward to express the connection between vapour pressure and temperature, and some of these find useful application in engineering practice. For many reasons formulae which have a theoretical basis must, however, be considered the more important, and it may be shown that if the vapour be assumed to conform to the requirements of the ideal gas equation, thermodynamic considerations lead to the relation $d \log p/dT = \lambda/RT^2$ in which λ is the heat of vaporization per gram-molecule at the absolute temperature T . If λ is independent of the temperature, this differential formula may be shown to be equivalent to the vapour pressure formula $\log p = C + k/T$, in which C and k are constants. If λ varies with the temperature in accordance with $\lambda = \lambda_0 + aT + bT^2 + cT^3 \dots$, the integration of the differential expression leads to the somewhat more complicated formula:

$$\log p = C_0 + k_1/T + k_2 \log T + k_3 T \dots$$

in which the coefficients $k_1, k_2, k_3 \dots$ are related to $a, b, c \dots$ respectively. This thermodynamic vapour-pressure formula is in accord with the observed variation of the vapour pressure over a very wide range of temperature, as may be seen by reference to the data for mercury. The calculated vapour-pressures in this case are derived from:

$$\log p = 10.5724 - 3342.26/T - 0.847 \log T$$

| T° (abs.) | Vapour Pressure of Mercury | | | | | | |
|------------------|----------------------------|--------|--------|---------|--------|------|-------|
| | 280.1° | 323° | 427.2° | 495.15° | 630.5° | 923° | 1151° |
| p obs. | 0.0367 | 0.0113 | 3.49 | 34.4 | 767.5 | (34) | (161) |
| p calc. | 0.0369 | 0.0126 | 3.32 | 34.7 | 794 | (36) | (157) |

At the two highest temperatures the pressures are expressed in atmospheres; for the other temperatures the numbers refer to mm. of mercury. It may be noted that the differential vapour-pressure formula which has been considered here represents a quantitative statement of the influence of temperature on the equilibrium between the liquid and its vapour. In accordance with this, the vapour-pressure formula may be regarded as a particular case of a more general expression which is applicable to states of equilibrium in both homogeneous and heterogeneous systems. In the general case, the equilibrium at a given temperature is determined by a constant K , the variation of which with the temperature is given by:

$$d \log K/dT = Q/RT^2$$

in which Q is the heat change associated with the chemical or physical transformation concerned. This general form of the equation is the quantitative expression of the "law of mobile equilibrium," according to which the alteration of one of the factors determining the state of equilibrium in a system, which is capable of internal adjustment, is accompanied by a change which tends to annul the effect of the original alteration. If the temperature of such a system is raised, the resulting internal adjustment must be accompanied by the absorption of heat, and the fact that the vapour pressure of a liquid always rises with the temperature is directly connected with the fact that vaporization involves the absorption of heat. The recognition of the law of mobile equilibrium, which applies equally to changes produced by pressure and temperature variations, is mainly due to H. Le Chatelier and Jacobus Henricus van't Hoff.

OPTICAL PROPERTIES

Refractivity.—The change in the direction of a homogeneous ray of light when it passes from air into a denser medium is termed refraction. This property of the medium is suitably measured by the index of refraction $n = \sin i / \sin r$, in that the influence of the angle of incidence is thereby eliminated. The re-

fractive index is determined by the relative velocities of light in air and in the medium, and this depends on the wave-length. The choice of wave-length in actual experiment is largely determined by the ease with which homogeneous beams of certain wave-lengths can be obtained. Apart from the arbitrariness which is involved in the selection of a particular wave-length for the comparative study of the refractivity of different substances, it is to be noted that the refractive index (say n_D for the sodium D line) depends on the temperature, pressure and other factors. This variability of the refractive index is responsible for the fact that other quantities have been suggested as a more suitable measure of refractivity. The expression $r_1 = (n-1)/d$ was suggested by J. H. Gladstone and T. P. Dale, and the relation $r_2 = (n^2-1)/(n^2+2)d$ by H. A. Lorentz and by L. Lorenz. The former is purely empirical, but the latter has some theoretical justification. Both these r quantities are insensitive to changes of temperature, and the second has the very important additional qualification that its magnitude for a given substance is nearly the same whether the substance is in the liquid or gaseous state. This is shown by H. H. Landolt's data for the specific refraction (r_2) of water, alcohol and chloroform.

| Specific Refractivities $r_2 = (n^2-1)/(n^2+2)d$ | | | |
|--|--------|---------------|------------|
| | Water | Ethyl alcohol | Chloroform |
| Liquid state | 0.2061 | 0.2807 | 0.1791 |
| Gaseous state | 0.2068 | 0.2805 | 0.1796 |

In order to provide an appropriate comparative basis for these measures of refractivity, it has been customary to multiply them by the molecular weights of the compounds concerned, whereby the so-called molecular refractivity $R = mr$ is obtained. The significance to be attributed to the quantity R is a matter which does not appear to have received much consideration. It may, however, be pointed out that $(n^2-1)/(n^2+2)d$, which was derived from a consideration of the dielectric action of insulating substances in terms of the Clausius-Mossotti theory, would seem to be a measure of the specific volume if n refers to infinitely long waves. It would therefore seem that the corresponding value of R may be regarded as providing an approximate measure of the molecular volume. In support of this view it may be noted further that the variations of $(n^2-1)/(n^2+2)$ from compound to compound are relatively small and that the differences in the R values are mainly determined by the changes in m or m/d . The use of molecular refraction in the comparison of the refractive powers of substances would therefore seem to have less justification than is usually assumed and the procedure followed in investigations which make use of this quantity may be regarded as largely empirical.

The relations disclosed by the results show that the molecular refractivity is additive in character and that its value for a given compound can be calculated from the molecular formula by the summation of constants (atomic refractions) which are peculiar to the constituent elements. As in the case of other physical properties, structural factors are clearly evident, and the correlation of the data for different groups of substances has made it necessary to attribute refraction effects to many different kinds of structural peculiarities such as double bonds, treble bonds, ring formation, conjugation, etc. When two double bonds are present in a molecule, the refractivity would seem to be dependent on their relative positions. When the double bonds are associated with a common carbon atom ($C=C=C$) or when they are separated by more than two carbon atoms, their influence is normal, but when they are in juxtaposition ($C=CH-CH=C$) or "conjugated," their influence is abnormally large. This effect is termed optical anomaly or exaltation. The constants assigned to certain atoms and structural elements from observations on the sodium D line are as follows:—C 2.42, H 1.00, O (doubly linked) 2.21, O(hydroxyl) 1.52, O(esters) 1.64, Cl 5.96, Br 8.86, I 13.90, double bond 1.73, treble bond 2.40.

Dispersivity.—Dispersivity is the name given to the difference between the specific refractivities for light of different wave-lengths. The wave-lengths usually chosen are the α - and γ -

hydrogen lines or the sodium and lithium lines. For comparative purposes, the specific dispersivity is given a molecular basis by multiplication by the molecular weight, but the justification for this procedure has been questioned by K. F. Auwers and F. Eisenlohr, who have attempted to correlate dispersive powers in terms of the specific dispersivities. Both methods of comparison show the existence of relations which resemble those shown by molecular refractivity. According to J. W. Brühl, dispersivity is pre-eminently a constitutive property and in consequence lends itself readily to the study of structural differences. It has been said that the presence of impurities in the compounds examined has a smaller disturbing influence on dispersivity than on refractivity.

Rotatory Power.—When a beam of plane polarized light is passed through certain substances, the plane of polarization is changed in direction; it is said to be rotated. Whilst for solid substances this may be due to an asymmetric disposition of the molecules in the crystalline aggregate, it can only be due to asymmetry within the molecules when this natural rotatory power is shown by isotropic fluids. The relations concerned are dealt with in the article on STEREOCHEMISTRY, and attention will be here confined to similar rotation effects which are shown quite generally by liquids when these are placed between the poles of an electromagnet and the beam of light is allowed to pass along the lines of force of the magnetic field. Our knowledge of magnetic rotatory power is based very largely on the work of W. H. Perkin, Sr., who measured the rotation produced by a column of liquid of fixed length and derived therefrom the specific rotatory power $r = \alpha/d$. Comparable values were sought by the introduction of the molecular weight in the usual way leading to the molecular magnetic rotatory power defined by $R = ma/d$. The comparison of such R values (expressed in relative measure, with water as the standard substance) has shown the existence of relations which are on all fours with those which have been described under refractivity.

Viscosity and Fluidity are reciprocal measures of internal friction. The precise definition of the coefficient of viscosity need not be considered here, for actual measurements are almost exclusively confined to the determination of relative viscosities. Such values are readily obtained from the times which are required for a given volume of liquid to flow through a capillary tube under precisely similar conditions. At one and the same temperature the viscosities for different liquids vary between very wide limits. The coefficients for ethyl ether, water and glycerol at 0° C are, for instance, 0.00286, 0.01793 and 46.0, respectively. With rise of temperature, the viscosity diminishes rapidly and in any comparative study of viscosities the question of temperature is very important. The temperatures selected by T. E. Thorpe and J. W. Rodger are those at which the temperature-viscosity curves have the same slope. At such temperatures the rate at which the viscosity changes with the temperature is the same for all substances, and consequently the influence of temperature may be said to be eliminated. On the supposition that the internal friction of liquids depends on the magnitude of the molecular surface, the product of the coefficient of viscosity (η) and the molecular surface has been used in the comparison of liquids with one another. Such molecular viscosities exhibit additive and constitutive relations of the usual kind.

Relations of a very different type are shown by certain other quantities which have been systematically examined in the liquid state. Notable examples are afforded by the Trouton ratio, *i.e.*, the ratio of the molecular heat of vaporization (λ) to the absolute boiling temperature (T), and by the Ramsay-Shields coefficient, which expresses the rate of change with the temperature of the molecular surface energy γ ($m \phi^{2/3}$ when γ is the surface tension, m the molecular weight and ϕ the specific volume). These coefficients have very nearly a constant value for large numbers of chemically different substances, and it has been supposed that deviations from the normal values afford evidence of the combination of the simple molecules to form more complex molecules (polymerization, *q.v.*; association, *q.v.*). The normal value of Trouton's function λ/T is 21, whilst for water the value is only

14.7. If water is a mixture of double and simple molecules in equilibrium with one another, as represented by $2\text{H}_2\text{O} \rightleftharpoons (\text{H}_2\text{O})_2$, there can be no doubt that the boiling-point will be appreciably higher than it would be if the liquid consisted entirely of simple molecules. Since the vapour consists almost entirely of simple molecules, it is also clear that the observed heat of vaporization is a complex quantity which represents the sum of the heat quantities involved in the depolymerization of the liquid molecules and in the volatilization of the simple molecules. The assumption of polymerization thus affords a possible interpretation of the abnormality of the Trouton ratio. In the case of the Ramsay-Shields coefficient, abnormally small values can be readily explained in terms of polymerization, but values greater than the normal present difficulties. Recent observations moreover on the properties of surface layers lead to the conclusion that the molecular condition in the surface is very different from that in the interior of a liquid. This fact would appear to have an important bearing on the interpretation which can legitimately be given to the observed value of the coefficient in question. (See SURFACE TENSION.)

THE SOLID STATE

General Characteristics.—Over a long period it was customary to speak of crystalline and amorphous solids, but the grounds on which this distinction was made are now regarded as unsatisfactory. Newer methods of analysis have in fact shown that many apparently amorphous substances are definitely micro-crystalline, while others appear to represent supercooled liquids of very high viscosity. The solid state is now generally identified with the crystalline condition, and matter in this form is characterized by its resistance to shearing stresses and by the fact that its physical properties vary with direction. This "anisotropy" of solids presents therefore a very definite contrast to the isotropy of liquids and gases. When crystals are formed under the usual conditions by the cooling of a liquid, they show a regular polyhedral structure and their physical properties are in general related to the external form (*see* CRYSTALLOGRAPHY). The normal development of such crystals involves a time factor, and when the conditions are such that separation of the solid takes place rapidly, there is a tendency towards the formation of granular aggregates in which the recognition of crystalline character may be a matter of some difficulty. In the matter of rigidity, the crystalline and liquid states may be said to overlap. The highly viscous, isotropic substances exemplified by the glasses, pass into the condition of fluid liquids in a gradual and continuous manner when the temperature is raised; there is no sudden transition in the properties such as is observed with crystalline solids at the melting-point. On the other hand, although most crystals are rigid and fracture when subjected to pressure, there are others in which the forces associated with the crystal structure are so weak that the crystals can be easily distorted and made to flow. Their behaviour in this respect simulates that of liquids, but they have the optical properties of crystals and possess a definite melting-point.

The directional properties and geometrical forms of crystalline solids are directly connected with regularities in the arrangement of the atoms or molecules within the crystal. These are no longer free to move from point to point, but occupy definite mean positions in the space lattice of the crystal. Their kinetic energy is represented by small vibratory or oscillatory movements about these mean positions. When, by a sufficient rise of temperature, the amplitude of the oscillatory motion becomes sufficiently great for the molecules to escape from the action of the force which tends to restore them to their mean positions, the solid melts and the vibratory motion is replaced by the random translatory motion characteristic of the liquid state. The determination of the arrangement of the mean positions has been made possible by the fact that the regularly disposed rows and planes of atoms (molecules) give rise to interference effects when the crystals are submitted to a beam of X-rays, that is to say, to radiation of a wavelength which is of the same order of magnitude as the distances which separate the atomic centres. The X-ray spectra obtained

in this way by M. Laue, W. H. and W. L. Bragg and others afford precise information relative to the architecture of the crystals. For strongly polar substances, such as sodium chloride, it is found that the points of the crystal lattice are occupied by positively charged sodium atoms and negatively charged chlorine atoms. Each sodium ion bears exactly the same relation to six chlorine ions which may be supposed to occupy the central points of the faces of a cube which has the sodium ion at its centre. Each chlorine ion is similarly disposed with respect to six sodium ions. The material structural elements, in other words, are the sodium and chlorine ions, and molecules of sodium chloride in the ordinary sense are non-existent. Substances of non-polar character give X-ray spectra, on the other hand, which clearly show that the lattice points are associated with molecular units which are, however, oriented in a perfectly definite manner. The patterns presented by such structures can always be described in terms of a unit or elementary lattice which may contain one, two or more molecules.

Polymorphism.—The one-time supposition that every substance was unique in its crystalline form has been definitely disproved by the discovery of isomorphism, according to which different substances may crystallize in the same form, and of polymorphism, according to which the same chemical substance may have different crystalline forms. In some cases, *e.g.*, the rhombic and monoclinic forms of sulphur (*q.v.*), the two crystalline forms are interconvertible. The change takes place at a definite temperature known as the transition temperature. Below 96° C rhombic sulphur is the stable form; above 96° the stable form is monoclinic and melts at 119° . Superheating readily occurs, however, and rhombic sulphur may be readily heated to its melting-point (113°). The transition temperature is the only temperature at which the two solid forms can coexist in equilibrium at atmospheric pressure and at which their vapour pressures are therefore the same. The relations between the two solid forms at the transition point are clearly very similar to those between a solid and the corresponding liquid at the freezing-point of the latter. In some cases, *e.g.*, benzophenone, the two crystalline forms are not interconvertible. One of them is unstable at all temperatures and the transition point (*i.e.*, the point of intersection of the vapour pressure curves) is higher than either of the melting-points. When a substance can exist in several crystalline forms the equilibrium relations may be of rather complex character, but the correlation of these is greatly facilitated by the use of the phase rule. According to this, the number of phases, *i.e.*, the physically distinct parts of a system, which can coexist in equilibrium is determined by the number of the components. This represents the smallest number of chemical constituents in terms of which the composition of the several phases can be expressed. If P is the number of phases and C the number of the components, the maximum value of P is $C+2$. When this relation obtains, the equilibrium is completely defined by the nature of the system and the variable factors represented by temperature, pressure and concentration can have only perfectly definite values. If $P=C+1$, one of these factors must have a value assigned to it before the equilibrium is determined. If $P=C$, two such factors must have determined values. The number of the variables to which arbitrary values must be given to specify the precise nature of the equilibrium is termed the number of degrees of freedom (F) and in accordance with the "phase rule," $F=C+2-P$. In the simplest possible case where $C=1$, the number of degrees of freedom is 2, 1 or 0 according as $P=1$, 2 or 3. The whole of the relations involved can be conveniently represented by a diagram on which the pressure and temperature are taken as the co-ordinates. Such a diagram, showing the relations between rhombic, monoclinic, liquid and sulphur vapour is presented in fig. 3. Invariant systems ($F=0$) are represented by the points at which three curves intersect. The point A corresponds with the system rhombic-monoclinic-vapour, B with monoclinic-liquid-vapour and C with rhombic-monoclinic-liquid. Univariant systems ($F=1$) are represented by points on the curves. The curves r , m and l define the respective conditions under which rhombic and vapour, monoclinic and vapour, liquid and vapour can coexist in

equilibrium. In the same way the curves rm and ml give the conditions for equilibrium between rhombic and monoclinic and between monoclinic and liquid. Bivariant systems ($F=2$) are those represented by all other points and the regions of stability of the single phase systems—rhombic, monoclinic, liquid and vapour, are shown by R , M , L and V .

Heat Capacity.—According to the empirical relation discovered by P. L. Dulong and A. T. Petit (1819), the product of

FIG. 3.—PHASE RULE DIAGRAM (NOT TO SCALE) FOR SULPHUR, SHOWING DEPENDENCE OF VAPOUR, LIQUID, MONOCLINIC AND RHOMBIC FORMS ON PRESSURE AND ON TEMPERATURE

the specific heats of the elements and their atomic weights is approximately constant= 6.4 . This relation was confirmed by Regnault, but it was found necessary to recognize that the non-metallic elements of low atomic weight are exceptions to the rule in that their atomic heats are abnormally small, *e.g.*, carbon 1.8, boron 3.7, beryllium 3.7, silicon 3.8, phosphorus 5.4. According to F. E. Neumann and H. Kopp the molecular heats of compounds can be expressed approximately as the sum of the atomic heats of the constituent elements, from which it may be inferred that the heat capacity is within narrow limits the same whether the elements are free or chemically combined. The experimental results summarized in the rule of Dulong and Petit are in agreement with the deductions from the classical kinetic theory. According to this the atoms in the solid element have three independent modes of movement associated with the three directions of space, and since each degree of freedom corresponds with a heat capacity of $R/2$ calories, and kinetic energy of the oscillatory type is necessarily associated with an equivalent amount of potential energy, it follows that the atomic heat capacity is $6 \times R/2 = 6.0$ calories. This value should, however, be independent of the temperature, which is contrary to experiment, for measurements of the specific heats of the elements and of their compounds at very low temperatures have shown that the heat capacity begins to fall rapidly when the temperature is sufficiently low and tends towards a zero value. The explanation of this behaviour represents one of the most important achievements of the quantum theory. Albert Einstein has indeed shown that the observed dependence of the heat capacity on the temperature is in general agreement with the requirements of the quantum theory of heat exchange. The formula given by Einstein, which assumes that the energy absorbed is associated with a particular frequency, has since been modified by Peter Debye and others. According to these later views the characteristic frequency of Einstein represents the upper limiting value of the complete series of frequencies which can actually be absorbed by the atoms. The

observed atomic heats of copper and those calculated on the basis of the quantum theory are compared below:

| | | | | | | |
|-----------------|-------|-------|-------|------|------|------|
| Temperature (A) | 23.5° | 33.4° | 88.0° | 137° | 200° | 450° |
| C_p (obs.) | 0.22 | 0.54 | 3.38 | 4.57 | 5.79 | 6.09 |
| C_p (calc.) | 0.15 | 0.59 | 3.39 | 4.65 | 5.75 | 6.03 |

At relatively high temperatures there is no difference between the requirements of the classical and quantum theories. The fact that the value of C_v becomes considerably greater than 6.0 at very high temperatures—for tungsten at 2,000° C, $C_v = 7.35$ —is said to be due to the thermal agitation of the electrons.

Electrical Conductance.—Electrical conducting power similar to that possessed by metals and alloys is shown by certain non-metals, *e.g.*, by carbon in the form of graphite, by compounds of some of the less electro-positive metals with elements of the oxygen group, *e.g.*, pyrites, oxides of lead and iron, and also by compounds of the type represented by CH_3Hg . At very low temperatures this metallic conducting power increases very greatly. The resistance of tin becomes vanishingly small at 3.8° A, and that of thallium at 2.3° A. In other cases, *e.g.*, platinum and calcium, the resistance falls to a low limiting value which is independent of the temperature. The supposition that metallic conduction of electricity and heat is due to the movement of free electrons is difficult to reconcile with the very small heat capacity of the electrons, and the suggestion has been made that a metal represents a structure with interleaved ionic and electron lattices, electrical conductance being associated with the movement of the electron lattice through the ionic lattice. Electrolytic conductance of the type exhibited by fused salts and salt solutions is also met with in the case of certain solid salts. Whereas the conductance in liquids is associated with the movement of both positive and negative ions, the passage of the current through these solid compounds is due either to the positive or to the negative ion. In silver chloride and cuprous sulphide the carrier is the metallic ion, whereas the chlorine ion is the migratory constituent in lead chloride. Both metallic and electrolytic conduction are shown by other solid salts.

PROPERTIES OF MIXTURES

The term mixture is applied to a system in which the constituent particles are directly or indirectly distinguishable from one another. When the difference can be recognized directly or by the use of some optical magnifying device, it is customary to speak of mechanical mixtures, whilst the term solution is reserved for mixtures in which the constituent particles are of molecular dimensions. There is no fundamental difference between the two classes of mixtures for they can all be resolved by the application of mechanical forces, for example, by a process of centrifuging. Gases are all completely miscible with one another, but miscibility in the liquid and solid states is much less general. Some pairs of liquids are miscible in all proportions and complete series of mixed crystals are formed by certain pairs of crystalline solids. Other pairs of liquids and solid substances are practically immiscible. A third group is formed by pairs which are miscible in limited proportions. Miscibility depends upon the temperature and in general is favoured by the chemical similarity of the substances concerned. Water does not mix with hydrocarbons, is completely miscible with methyl and ethyl alcohols, partially miscible with butyl and amyl alcohols, but practically immiscible with higher members of the alcohol series.

When two partially miscible liquid substances A and B are brought together, then, in general, two layers are formed which contain different proportions of A and B. The composition of these layers (so-called conjugate pairs) depends on the temperature. As a rule, the difference between the conjugates

diminishes with rise of temperature and in some cases may ultimately disappear. The temperature at which this occurs is the "critical solution temperature" and above this the two substances are miscible in all proportions. Increased miscibility is sometimes produced by a fall of temperature and a few pairs of substances are known for which both upper and lower critical temperatures can be observed. Nicotine and water, for example, are completely miscible below 61° C and above 210° C; between these limits they are only partially miscible. Fig. 4 shows these relations: conjugate pairs are connected by horizontal lines.

In gaseous mixtures at the ordinary pressure, the molecules are so widely separated that the effects of intermolecular forces can be almost entirely ignored. In the absence of chemical interaction between them, the independence of the molecules would lead us to expect that the properties peculiar to the molecules of a substance A will not be affected by admixture with the molecules of B. In these circumstances, the properties of a gaseous mixture which contains A and B in the molecular ratio $(1-x):x$ should be given by the simple mixture rule, which may be written $P_x = (1-x)P_A + xP_B$, where P_A , P_B and P_x represent the values of the property for A, B and the mixture respectively. Dalton's law of partial pressures affords an example of this relation.

Property-composition Curves.—Since the properties of pure liquids are largely dependent on the attractive forces between the molecules, it is extremely unlikely that the relations connecting the properties of liquid mixtures with those of their components can be of the same simple nature as those which characterize the corresponding gaseous systems. In some cases the mixing of two liquids is accompanied by very pronounced changes in volume, by a rise or fall of temperature and by other effects. For other liquid pairs, such effects are so small as to be scarcely measurable. The relations between the properties of liquid mixtures and those of their components may be conveniently shown by plotting the measured property against the composition of the mixture. The property-composition curves obtained in this way sometimes deviate but little from the straight line which corresponds with the simple mixture rule, but for other mixtures large deviations are found, and not infrequently the curves show a maximum or a minimum.

In the interpretation of such curves, two different points of view have been adopted. On the one hand, the changes in physical properties have been attributed to variations in the molecular attractive forces. If the attractive forces between the unlike molecules and between the two sets of like molecules are denoted respectively by a_{AB} , a_A and a_B , then if a_{AB} is much greater than a_A and a_B , it may be anticipated that the substances in question will mix readily, whilst if a_{AB} is much smaller than a_A and a_B , there are reasonable grounds for the anticipation that most will be only partially miscible. In the former case, pronounced changes in the physical properties may be expected to accompany the mixing of the two substances, whereas if the attractive forces between the unlike molecules are of the same order of magnitude as the forces between the two sets of like molecules, it may be supposed that admixture will not be accompanied by any pronounced change in the general physical properties.

In contrast with the above view, some authors maintain that well-marked changes in physical properties afford evidence that the mixing of the two substances in question has resulted in chemical interaction. It may be that these two views are not so widely different as would be suggested by the arguments of the respective protagonists, for the action of molecular forces of sufficient magnitude between the molecules of A and B may lead to a form of physical association which is by no means easy to distinguish from what would be described as the chemical combination of molecules of A and B. In any case it is probable that deviations from the simple mixture rule may be due in part to differences in the acting molecular forces, whilst the formation of definite chemical compounds may sometimes be the chief cause of the departure.

Theoretical considerations based on the law of mass action (see CHEMICAL ACTION) indicate that if the two components of

FIG. 4.—DIAGRAM SHOWING THAT WATER AND NICOTINE ARE COMPLETELY MISCIBLE BELOW 61° C AND ABOVE 210° C

a liquid mixture combine together to form a compound, the proportion of this in the mixture will be greatest when the composition of the mixture, as a whole, is the same as that of the compound. If such compound formation is the cause of the deviation in the physical properties from what would be expected according to the simple mixture rule, the determination of the composition of that liquid mixture for which the deviation has a

FIG. 5.—DIAGRAM SHOWING THE RELATION BETWEEN THE COMPOSITION OF A LIQUID MIXTURE AND ITS BOILING POINT. LIGHT CURVES INDICATE COMPOSITION OF VAPOUR; E.G., A LIQUID OF COMPOSITION Y GIVES OFF A VAPOUR Z

maximum value should give the composition of the compound. In support of this and of the chemical theory, it is frequently found that maximum deviation occurs at a point which corresponds with a simple molecular ratio of the components. For example, the volume and viscosity curves indicate the existence of the compound $C_2H_5OH, 3H_2O$ in ethyl alcohol-water mixtures and the formation of $C_5H_5N, 2H_2O$ in mixtures of pyridine and water. The viscosity curve for methyl alcohol-water mixtures suggests the formation of the compound $2CH_3OH, 3H_2O$, and the maximum deviation is independent of the temperature between 10° and 60° C.

If the curves for different properties show a maximum deviation at the same composition and if this composition is not affected appreciably by change of temperature, there would seem to be strong evidence for the formation of a compound represented by the corresponding formula. When a single stable compound is formed, its presence should be clearly indicated, but if the compound is relatively unstable and therefore present in small quantity the evidence may be much less conclusive. Furthermore, when more than one compound is formed, the property-composition curves may easily lead to erroneous conclusions, for if the compounds A_2B and AB_2 are actually present, the maximum deviation of the experimental curve from the simple mixture line will probably occur at a point which falls between A_2B and AB_2 and may indeed suggest the formation of the compound AB .

The properties of binary liquid mixtures which have been systematically examined include volume, viscosity, vapour pressure, dielectric capacity, heat capacity, heat of mixing, etc. In the graphic representation of the results it is necessary to correlate the units in terms of which the property is measured with those which are used to represent the composition of the mixture. If the composition is expressed in molecular percentages, in which case the abscissa corresponds directly with the relative numbers of molecules of A and B in the various mixtures, the property should also be evaluated on a molecular basis. The plot of the

specific value of a property against the molecular composition would obviously have much less justification. In actual practice, the importance of such matters has not received adequate attention and to this fact must be attributed some of the difficulties which have been met with in the interpretation of property-composition curves.

Boiling-point and Freezing-point Curves.—Of the many properties which have been examined, special consideration may be given to boiling-point and freezing-point curves, both of which are of practical importance in their bearing on the processes of fractional distillation and crystallization (see DISTILLATION). Boiling-point curves may be divided into two main groups. In the first the boiling-points of all mixtures fall between those of the components (fig. 5; curve I), whilst the second is characterized by the occurrence of maximum or minimum boiling-point mixtures (curve II). Since the vapour given off by a liquid mixture always contains the more volatile component in greater proportion than the liquid phase (cf. dotted curve I) mixtures of the first type may be completely separated from one another by an efficient form of fractional distillation apparatus. This, however, is not possible for mixtures of the second type. Fractional distillation of these leads to separation into two fractions, represented respectively by pure A or pure B and a liquid X, which has the composition of the maximum (minimum) boiling-point mixture. The maximum or minimum boiling-point mixtures are indeed sharply distinguished from all other mixtures by the fact that the liquid and vapour phases are identical in composition. In this behaviour they resemble pure substances and are termed azeotropes. It was at one time supposed that azeotropes corresponded with definite compounds but the fact that the composition of the azeotrope varies with the pressure indicates that this view is untenable.

FIG. 6.—DIAGRAM SHOWING FORMATION OF MIXED CRYSTALS OF GOLD AND OF PLATINUM Crystals of composition S separate from the liquid L. Then the gold content of the liquid and the crystal increases continuously during solidification

FIG. 7.—DIAGRAM SHOWING FREEZING POINT FOR MIXED MOLTEN MERCURIC BROMIDE, $HgBr_2$, AND MERCURIC IODIDE, HgI_2 From any mixture, mixed crystals separate so that liquid approaches condition M, where it freezes as a whole like a single compound

Freezing-point curves and boiling-point curves are somewhat different from other property-composition curves in that they correspond with conditions which permit of the coexistence of the liquid with a solid or a vapour phase. In accordance with the fact that vapours are completely miscible, the boiling-point curves are nevertheless continuous, whereas the freezing-point curves are generally discontinuous. This is due to the circumstance that miscibility of substances in the solid state is very limited and that the freezing-point depends on the nature of the solid substance which separates out. Many cases are known in which the same liquid mixture has two or more freezing-points, the temperature varying with the product of crystallization.

When the components of a binary liquid mixture are completely miscible in the solid state, the two types of freezing-point curves which are obtained are closely similar to the boiling-point curves already described. For mixtures of the first type the freezing points lie between those of the pure components. In general, the composition of the mixed crystals which separate out differs from

that of the mother-liquor, and the relation between the two can be represented on the freezing-point diagram by two curves—the so-called liquidus and solidus (see fig. 6). Corresponding points *L* and *S* on these curves, i.e., points on the same horizontal line, are conjugate in the sense in which this term is applied to two coexisting liquid phases. Binary mixtures of the second type show either a maximum or a minimum freezing-point, at which the liquidus and solidus meet (cf. fig. 7). If the proportions of the components in the mixture correspond with this point, the liquid freezes at a constant temperature and then behaves like a pure substance. A vertical line drawn through the maximum (or minimum) point divides the complete series of mixtures into two subgroups, the behaviour of which is exactly similar to that of mixtures of the first type.

If the components of a binary liquid mixture are immiscible in the solid state, the freezing-point curve is discontinuous. In the simplest case, it consists of two descending branches which intersect at the eutectic point (cf. fig. 8; curve I). The eutectic mixture is that mixture which has the lowest freezing-point, and is further distinguished by the circumstance that the two components crystallize out simultaneously in the proportions in which they are present in the eutectic liquid. The freezing temperature therefore remains constant. Mixtures which contain an excess of A (or B) in comparison with the eutectic mixture deposit A (or B) on freezing. This alters the composition of the residual liquid and the freezing-point falls continuously until the eutectic point is reached. The solidification is then completed at constant temperature.

If one or more compounds separate out on freezing, the diagram is of a more complicated type. Fig. 8, curve II, illustrates the relations when a compound of the type AB crystallizes out. There are now four freezing-point curves and two eutectic points. The two intermediate curves intersect in a point which corresponds with the freezing-point of the compound AB. In spite of the increased complexity of the diagram, the relations are very similar to those which characterize the simpler form, and complex diagrams of this kind can be resolved into a series of simple diagrams by drawing vertical lines through the points which correspond with the several compounds formed. If three such compounds A_2B , AB and AB_2 are formed, this process leads to four separate freezing-point diagrams, for which the components are A and A_2B , A_2B and AB, AB and AB_2 , and AB_2 and B respectively. Fig. 9 shows the relations for water and sulphur trioxide where five compounds are formed. It frequently happens that a solid compound decomposes into its components below its melting-point. This is the case for Glauber's salt, $Na_2SO_4 \cdot 10H_2O$, which decomposes at $32.38^\circ C$. When such changes occur, the freezing-point diagram shows one curve only for the compound.

FIG. 8.—CURVES FOR MIXED LIQUIDS

1. Parts of mixed liquids are immiscible in solid state, but liquid freezes as a whole at fusing point, E, after depositing excess of A or B
2. When A and B form a compound there are almost two curves of type I, E_1 and E_2 being the two fusing mixtures

FIG. 9.—DIAGRAM SHOWING FORMATION OF FIVE COMPOUNDS BETWEEN WATER, AND SULPHUR TRIOXIDE, OF MELTING POINTS $-25^\circ C$, $-139^\circ C$, $+9^\circ C$, $+10^\circ C$, AND $+36^\circ C$, WITH CORRESPONDING FUSING POINTS

Changes, very similar to those which characterize the equilibria between solid and liquid phases, also occur in systems which are entirely solid, and these are largely responsible for the variations which are found in the properties of solid mixtures such as the alloys (*q.v.*). An exact knowledge of the equilibrium relations is of the greatest importance, for the properties of such solids depend not only on the composition but on the constitution as represented by the phase equilibria. The changes produced in the physical properties of alloys by thermal and mechanical treatment are often directly due to changes in the phase equilibria.

ANALYTICAL CHEMISTRY

The specific purpose of analytical chemistry is the resolution of a compound or mixture into its constituent parts or elements by methods which are *qualitative* when the nature only of these constituents is determined, or *quantitative* when their actual quantity or proportion is ascertained. The methods of chemical analysis may be classified as *dry*, consisting of the examination of the substance in the dry state, and *wet*, in which a solution of the substance is treated with other substances of known character, termed *reagents*, to promote a chemical change or *reaction* whereby a new compound of distinctive properties is produced. In quantitative work the methods of analysis may be subdivided into (a) *gravimetric*, in which the constituent to be determined is either isolated as such, as in the case of electrolysis, or as a compound of definite chemical composition; (b) *volumetric*, in which the volume of a reagent solution of known strength required to produce a certain definite reaction is measured. Colorimetric and gasometric methods are, strictly speaking, branches of volumetric analysis, as indeed is gas analysis (see below). Microchemical methods, which, however, involve a special technique, have been developed both on the qualitative and quantitative sides.

INORGANIC ANALYSIS

Analytical chemistry, upon which all other branches of the science are ultimately dependent, has its source in the writings of the chemist-pharmacists of the iatrochemical period. Tachenius recognized many metals in solution together by their reactions in the wet way, but it was not until the phlogistic period that any systematic progress was made, more particularly by Boyle, to whom we owe the term *analysis*. Many of the reactions still utilized in qualitative work were known to Boyle, who also introduced certain plant extracts, notably litmus, for the recognition of acids and bases. Other workers of this period were Hofmann, Marggraf (who introduced the microscope into chemistry), Scheele, and especially Bergman, who devised methods by which the metals might be separated into groups according to their behaviour with certain reagents. The blowpipe (*q.v.*) was introduced into dry qualitative analysis by the mineralogist, Cronstedt, who applied it to the examination of ores, although it was left to Berzelius and Hausmann to bring about its general application. The colorations which sodium and potassium salts impart to the flame were known to Marggraf, but it is to Bunsen, who, with Kirchhoff, devised spectrum analysis, that the full value of the flame test is due.

While the work of the phlogistic period in this field was mainly of a qualitative character, some attempts of a quantitative nature

were made by Marggraf and Black, while Bergman realized that elements need not be separated as such but might be isolated in the form of some suitable insoluble compounds. Klaproth, who with Vauquelin developed the quantitative analysis of minerals, proposed the ignition of precipitates before weighing them, if they were not decomposed thereby. Lavoisier, with his grasp of the importance of the composition by weight of chemical compounds, and because of his systematic use of the balance, must be considered as the first great exponent of quantitative analysis. The substantiation by Richter, and, independently by Proust, of the law of constant proportions and the formulation of the atomic theory by Dalton combined to give a fresh impetus to the development of quantitative analysis, subsequently placed on a firm basis by Berzelius. The later researches of Rose, Wohler and Fresenius standardized various methods of analytical chemistry.

The quantitative precipitation of metals by the electric current, although known to Faraday, was not applied to analytical chemistry until Gibbs, in 1865, worked out the electrolytic separation of copper. Since then the subject has been extensively studied, more particularly by Classen.

Volumetric analysis, possessing as it does many advantages over the gravimetric method, especially in technical work, was founded by Gay-Lussac, although rough application had been previously made; the advantages of his carefully worked out methods of chlorimetry (1824), of alkalimetry (1828), and of the chloride-silver titration (1832) were but slowly recognized. It was not until the application of potassium permanganate to the estimation of iron by Margueritte (1846) and of iodine and sulphurous acid to the estimation of copper and many other substances by Bunsen, that volumetric methods took their proper place alongside the gravimetric. Since that time, these methods have been rapidly developed, particularly by Mohr and Volhard.

The technique of quantitative micro-analysis has been developed mainly by Pregl, although Emich had previously indicated the possibility of working with small amounts of inorganic materials. The same basic principles and methods hold as for macro-analysis, but apparatus and manipulation are necessarily modified when quantities of the order of a few milligrams only are being handled. The same period has seen the advance of the method of potentiometric titration, although this was first put forward in the case of acids and alkalis by Böttger as early as 1897.

Qualitative Inorganic Analysis.—Any inference drawn from the results of the qualitative examination of a substance, whether by dry or wet methods, must always be confirmed by further tests; moreover, it should not be overlooked that the normal course of a particular reaction may be completely prevented by the presence of interfering substances.

Dry Methods.—(1) *Effect of Heat.*—The substance when heated in a hard glass tube may evolve water, condensing on the cooler parts of the tube, derived from substances containing water of crystallization or of constitution and from certain ammonium salts. Its reaction to litmus paper should be observed; alkalinity is probably due to ammonia, acidity to readily decomposable salts.

Oxygen results from the decomposition of peroxides, chlorates, nitrates, iodates and similar oxygenated compounds, and also from oxides of the noble metals; carbon dioxide from carbonates and organic substances, usually accompanied in the latter case by charring; sulphur dioxide from many sulphides and thiosulphates. Chlorine, bromine and iodine are evolved from certain halide salts, particularly in the presence of oxidizing agents; oxides of nitrogen from nitrates. Some cyanides evolve cyanogen or hydrocyanic acid and possibly ammonia in the presence of water. All fluosilicates (silicofluorides) are decomposed on heating, evolving silicon fluoride.

A white sublimate is given by ammonium halide salts, mercurous chloride and bromide, oxides of arsenic; a yellow sublimate may consist of sulphur (reddish brown when molten), arsenic sulphide and mercuric iodide (turning red on rubbing). A blackish deposit results from the condensation of violet iodine vapour or of mercuric sulphide, while most mercury compounds other than those mentioned give a grey deposit. Metallic mercury and arsenic appear as minute globules and a grey mirror.

Colour changes on heating and cooling afford useful information; zinc oxide, titanium dioxide and stannic oxide are of yellow tone when hot, becoming white or whitish on cooling. Lead and bismuth oxides are, short of fusion temperature, brownish red when hot and yellow when cold. The oxides of manganese, cadmium, copper and iron also supply information by this test. All salts of organic acids are decomposed on ignition, usually with charring; the base will be left as carbonate, as oxide, or even reduced to the metallic state, according to the particular metal present.

(2). *Blowpipe Tests.*—The substance is heated in a hollow on a charcoal block in the reducing flame of a blowpipe. Oxygenated salts such as chlorates and nitrates cause deflagration; salts of the alkali metals tend to fuse into the charcoal. The oxides or stable salts of the alkaline-earth metals and of magnesium, zinc, and aluminium give an infusible residue, white when cold, which in the case of strontia, lime, magnesia or zinc oxide glows brightly in the blowpipe flame. The infusible mass is then moistened with cobalt nitrate solution and again heated; a pink coloration indicates magnesia (with a tendency to violet if present as phosphate or arsenate), a green colour is afforded by zinc oxide, while a blue suggests aluminium, possibly silica, or alkaline-earth phosphates. If any other reaction occurs on this direct heating, it is better to carry out a further more decisive test on a mixture of the substance with sodium carbonate. Metallic globules are obtained with copper, gold, silver, lead, tin, bismuth and antimony, together with formation of incrustations in the case of silver, lead, tin, bismuth and antimony; arsenic and cadmium also give analogous incrustations.

(3). *Bead Tests.*—The colourless fluxes obtained by fusing borax (for coloured salts) or microcosmic salt (for silica, or if the substance is white) on a loop of platinum wire are capable of dissolving many metallic salts, often with production of characteristic coloured glasses or enamels; the colour may differ according as the bead is heated in the oxidizing or the reducing flame. Chromium gives a green, cobalt a blue bead; copper in the oxidizing flame a bead, green when hot, blue on cooling, and with a tendency to red in the reducing flame. Iron gives yellow and greenish; nickel, brownish and yellow-grey; uranium and vanadium, yellow and green; manganese, violet and colourless, in the oxidizing and reducing flames respectively. Silica with microcosmic salt usually, but not invariably, gives a semi-transparent bead.

(4). *Flame Colorations.*—When volatilized in a non-luminous flame, the salts of certain metals display characteristic colorations. This test is carried out by introducing into the flame by means of a platinum wire a portion of the substance, preferably moistened with hydrochloric acid, since the chlorides are comparatively volatile salts. Sodium gives an intense yellow coloration, potassium violet, rubidium and caesium bluish-violet (the latter blue when really pure), calcium red, strontium and lithium crimson, barium yellowish-green and copper bright green; while lead, arsenic and antimony (which should not be tested on platinum) give a greyish-blue.

The utility of this test is not confined to direct observation, since the coloration due to one metal may completely mask that of others, and for such cases the use of light filters is of assistance. Cobalt glass completely absorbs the sodium yellow and thus permits the detection of potassium. The lithium and strontium colours are not cut out by this blue glass; a saturated solution of chrome alum effectively cuts out colorations due to sodium, calcium, barium, lithium and strontium and transmits only those due to potassium, caesium and rubidium; solutions of permanganate and indigo-carmin also cut out the sodium colour.

More definite, however, is the information afforded by observation of the flame through the spectroscopic, which is of particular value for ascertaining the purity of precipitates obtained in quantitative work. Of the rarer metals which give flame colorations, indium (blue) and thallium (green) were discovered by means of the spectroscopic, as indeed were also rubidium and caesium. The instrument is applicable to the detection of many other metals by examination of their spark spectra.

Wet Methods.—In qualitative analysis of a substance by wet

methods it is necessary to obtain it in solution. Portions should be successively tested with water, dilute acids, strong acids and aqua regia (*q.v.*), first in the cold and then with warming. For substances insoluble in all these reagents, fusion with sodium carbonate alone or in admixture with potassium nitrate, followed by acidification, must be employed. In certain cases sodium peroxide or potassium bisulphate (pyrosulphate) may be used, while for the investigation of some refractory silicates treatment with hydrofluoric acid in the presence of sulphuric acid is useful.

The procedure for the detection of metals in solution consists of separating them first into groups by means of volatile reagents; the group precipitates are then examined separately. From the cold solution, not too concentrated, hydrochloric acid (if this has not already been used in effecting solution) precipitates lead (in part), silver and mercurous salts. The filtrate is rendered nearly neutral and sulphuretted hydrogen passed in to saturation; this causes mercury (-ic), lead (incompletely removed in the foregoing operation), copper, bismuth, cadmium, arsenic, antimony and tin to be precipitated as sulphides; the filtrate from these is boiled until free from sulphuretted hydrogen, finally with addition of enough oxidizing agent such as nitric acid to convert iron from the ferrous to the ferric state. Ammonium chloride and ammonia are now added to precipitate aluminium, chromium, iron and titanium as hydroxides; if phosphoric acid is present, however, these metals are precipitated in part or wholly as phosphates, possibly together with some of the metals of later groups. In this case the precipitate is dissolved in a minimum of hydrochloric acid, a portion of the solution being specially tested for iron, and the remainder boiled with ammonium acetate and a slight excess of ferric chloride, whereby the phosphates are completely eliminated as ferric phosphate, together with the excess of iron as basic acetate; the filtrate is combined with that from the ammonia precipitation. It may be noted that some other acid radicals, *e.g.*, fluorides, borates and silicates, also interfere by precipitation at this stage, while in the presence of certain organic compounds, such as tartaric acid, precipitation in this group may be completely inhibited. From the filtrate from the iron group, ammonium sulphide precipitates nickel, cobalt, zinc and manganese, to the filtrate from which ammonium carbonate is added. A precipitate is obtained in the presence of calcium, barium and strontium, leaving sodium, potassium and magnesium in solution, the last of these metals not being precipitated by ammonium carbonate in the presence of ammonium salts. This completes the separation into groups.

Group I.—The white precipitate formed by cold hydrochloric acid is boiled with a considerable quantity of water, and the solution filtered immediately; lead chloride dissolves and may be identified by the yellow precipitate, insoluble in acetic acid but soluble in caustic soda, formed with potassium chromate. The residue on the filter paper is digested with ammonia, whereby silver chloride passes into solution, leaving a black residue of indefinite composition which retains the mercury. Silver chloride is reprecipitated from the ammoniacal solution by nitric acid.

Group II.—The precipitate formed by sulphuretted hydrogen may contain the black mercuric, lead and copper sulphides, dark brown bismuth and stannous sulphides, yellow cadmium and arsenic sulphides, orange-red antimony sulphide, dirty yellow stannic sulphide and whitish sulphur, this last resulting from the action on sulphuretted hydrogen of oxidizing agents such as ferric salts, chromates, nitrates, etc. Warming with yellow ammonium sulphide dissolves out the arsenic, antimony and tin sulphides, which are reprecipitated from the solution of sulpho-salts, after filtration, by addition of hydrochloric acid; tin is always reprecipitated as yellowish stannic sulphide. If traces of copper are being looked for, sodium sulphide should be used for this extraction; polysulphides are necessary to dissolve stannous sulphide. The mixture of the three sulphides is digested with warm ammonium carbonate solution, which dissolves the arsenic; this is reprecipitated on acidifying, after filtration, and confirmed by due tests. The residual sulphides of antimony and tin are dissolved in strong hydrochloric acid and these two elements tested for individually. When arsenates are present it is preferable to add sufficient sul-

phurous acid solution to reduce them to arsenites before passing in sulphuretted hydrogen.

The residue from the ammonium or sodium sulphide digestion is warmed with moderately dilute nitric acid, which dissolves the remaining sulphides, other than that of mercury, with separation of sulphur. A little sulphuric acid is added to the solution, together with an equal volume of alcohol; any white precipitate is lead sulphate. As the alcohol must now be boiled off, it is advisable to test separately for lead; if this metal is absent alcohol need not be used. Ammonia in excess added to the filtrate from the lead precipitates white bismuth hydroxide; in the event of the filtrate being colourless, direct passage of sulphuretted hydrogen precipitates yellow cadmium sulphide. A blue filtrate from bismuth indicates copper, and in this case sufficient potassium cyanide must be added to destroy the blue colour before testing for cadmium.

Group IIIa.—In the absence of phosphates (the presence of which is readily ascertained by warming with ammonium molybdate in nitric acid solution) this group consists of the gelatinous hydroxides of titanium and aluminium (white), iron (red-brown) and chromium (greenish), usually accompanied by a little zinc (especially when chromium is present) and manganese, and possibly traces of the group IV. metals precipitated by carbonate present in the ammonia. (To avoid this last contamination in quantitative work hexamethylenetetramine has been suggested in place of ammonia.) The precipitate is dissolved in a little hydrochloric acid; titanium is readily detected in a portion of the solution by the yellow colour it affords with hydrogen peroxide in acid solution. Another portion of the solution is tested for iron with potassium ferrocyanide (blue precipitate) or thiocyanate (deep red coloration), while the third portion is boiled with sodium peroxide until the excess of reagent is decomposed; this dissolves aluminium and chromium hydroxides, the latter being converted to the yellow chromate. By boiling the filtered solution with an excess of ammonium chloride, aluminium hydroxide is again precipitated.

Group IIIb includes the sulphides of cobalt and nickel (black), of zinc (white) and of manganese (usually buff coloured). The precipitate is digested with cold dilute hydrochloric acid and the solution filtered; the filtrate, which contains zinc and manganese, is boiled to expel sulphuretted hydrogen, and then hydrogen peroxide is added, followed by ammonium chloride and ammonia to precipitate manganese as a dark brown hydroxide. Zinc is detected in the filtrate by reprecipitation as sulphide, after decomposition of the peroxide by boiling. The presence of cobalt is readily ascertained in the black residue from the hydrochloric acid digestion by the borax bead test; the remainder of the sulphides is then dissolved in a little aqua regia, the solution diluted and rendered ammoniacal and an alcoholic solution of dimethylglyoxime added. Nickel is indicated by a yellow coloration, followed almost immediately by a red flocculent precipitate; in the presence of cobalt the filtrate is brown, turning deeper and redder on addition of ammonium sulphide.

Group IV.—The precipitated carbonates are dissolved in a little dilute hydrochloric acid and the flame test applied. To a portion of the solution, calcium sulphate solution is added; if precipitation is immediate, barium is indicated, but if delayed, strontium. In the absence of any precipitation, the remainder of the original solution is tested for calcium by addition of ammonia and ammonium oxalate. If, however, barium is present, ammonium acetate is added, followed by potassium chromate to precipitate barium chromate; strontium and calcium are again precipitated as carbonates and then dissolved in the minimum quantity of hydrochloric acid. Ammonium sulphate now serves to precipitate strontium, the filtrate from which is tested for calcium by means of ammonium oxalate as noted above.

Group V.—The basic radicals not precipitated by group reagents comprise magnesium, sodium, potassium and ammonium. The solution is evaporated to dryness and the residue heated to dull redness until cessation of fumes indicates that all ammonium salts have been expelled. The residue is dissolved in water and a portion tested for magnesium by the addition of ammonium chlor-

ride, ammonia and sodium phosphate. The presence of sodium and potassium is indicated by a flame test, but the introduction of sodium through the medium of the reagents must not be overlooked; potassium may be confirmed by precipitation as platinum-chloride or cobaltinitrite, while ammonia is tested for by boiling a portion of the original substance with caustic soda solution.

Alternative schemes of separation exist, and there are also numerous confirmatory tests for individual metals. It should be emphasized that any inference drawn from the result of the application of a particular group reagent presupposes the absence of all metals belonging to previous groups. The system outlined above includes only the commoner bases, but each of the rarer metals falls into one or other of the groups and for the sake of completion, these are now given without further comment than that the presence of these metals of necessity complicates the identification scheme described above.

Group I.—Thallium (-ous).

Group II.—Gold, the platinum metals, germanium, vanadium, tungsten, molybdenum, selenium, tellurium.

Group IIIa.—Uranium, beryllium, zirconium, hafnium, gallium, indium, thorium, columbium, tantalum, scandium, cerium and the other "rare-earth" metals.

Group IIIb.—Thallium (-ic).

Group IV.—Radium.

Group V.—Caesium, rubidium, lithium.

Acid Radicals.—The detection of acid radicals does not lend itself to such a systematic serial procedure as that available for the bases. Rose noted the nature and colour of the precipitates obtained in neutral and acid solutions with barium chloride, silver nitrate, mercurous nitrate and calcium chloride on separate portions of the solution. The method mostly in use, however, is that due to Bunsen, who divided the acid radicals into groups according to the solubility of the silver and barium salts. It is generally desirable to carry out these tests after removal of the heavy metals by suitable treatment with sodium carbonate; moreover, the solution should not be too strong.

Group I.—Silver salts insoluble in water and in nitric acid; barium salts soluble in water:—Chloride, bromide, iodide, ferro- and ferri-cyanide, thiocyanate, hypochlorite.

Group II.—Silver salts insoluble in water but soluble in nitric acid; barium salts soluble in water:—Sulphide, selenide, telluride, nitrite, acetate, cyanate, hypophosphite.

Group III.—Silver salts (a) white, (b) coloured, and soluble in nitric acid; barium salts insoluble in water but soluble in nitric acid:—(a) Sulphite, selenite, tellurite, phosphite, carbonate, iodate, borate, molybdate, selenate, tellurate, meta- and pyrophosphate; (b) phosphate, arsenate, arsenite, vanadate, thiosulphate, chromate, periodate.

Group IV.—Silver salts soluble, barium salts insoluble in nitric acid:—Sulphate, fluoride, fluosilicate (silicofluoride).

Group V.—Both silver and barium salts soluble:—Nitrate, chlorate, perchlorate, manganate, permanganate.

Group VI.—Non-volatile acids forming soluble alkali salts only:—Silicate, tungstate, titanate, columbate, tantalate, zirconate.

The acid radicals having been placed in their appropriate groups, special tests for the individuals are applied which cannot be detailed here. It is interesting to note that certain pairs of salts or free acids are incompatible in solution, thus iodic and hydriodic acids react to form iodine, hypochlorite and sulphite give chloride and sulphate, hydrosulphuric and sulphurous acids liberate sulphur.

Quantitative Inorganic Analysis.—While, broadly speaking, the methods of quantitative inorganic analysis by chemical means follow the lines outlined above in the qualitative scheme by wet methods, the many devices which are resorted to for the purpose of procuring clean and sharp separations and of ensuring that precipitates are obtained in a form most suitable for manipulation are learned by experience. In general, volumetric processes are quicker, especially where many samples of similar nature are being dealt with, but it is, at the least, unwise to apply such methods to a substance of unknown composition. For small

quantities, colorimetric or gravimetric methods are preferable, while for large amounts and for precision work gravimetric processes have the advantage that the product isolated and weighed may be examined as to purity.

Gravimetric.—In the ordinary course of events, gravimetric analysis by chemical methods is made up of the following operations: a solution of the weighed substance is treated with a particular reagent which precipitates the constituent to be determined in a suitable form, this is then filtered, washed and finally weighed after requisite treatment. Certain precipitations are best effected from hot solutions, others from cold; in some cases filtration may be carried out almost at once, whilst in others the precipitate should remain in contact with the liquor for several hours.

Filtration is effected by means (1) of folded paper discs of various texture specially prepared for the purpose; (2) of a pad of asbestos supported in a special form of crucible such as that designed by Gooch; or (3) of a porous "sintered" glass diaphragm fused into glass tubing. Whichever means is adopted, it is essential that the filtering medium should be subjected to the same heat treatment before the preliminary weighing as it will be subsequently (except when paper is to be incinerated).

Washing is generally necessary for the purpose of removing substances which are to be determined subsequently or which will interfere with the treatment of the precipitate, but at the same time it must not be carried too far. No substance is completely insoluble, and many of the compounds utilized in analytical work are appreciably soluble, even in the wash-liquors specially devised for use with them; it may even be necessary to apply correction for this solubility. In the case of heavy crystalline precipitates which settle readily, most of the washing can be carried out by decantation; precipitates which are light or bulky and gelatinous are transferred to the filter, the last traces being removed by mechanical means if necessary, and there washed by repeated treatment with water or other liquor. The filter should be allowed to drain as completely as possible between washings.

The precipitate is prepared for weighing by drying in an oven maintained at a definite temperature or by more drastic heat treatment. In the case of a precipitate on paper, ignition in a crucible may sometimes be carried out without any preliminary drying, sometimes after drying in a hot air-oven, while occasionally it is necessary to burn the paper apart from the precipitate before completing the ignition. All vessels after heating must be allowed to cool thoroughly in a desiccator before weighing; platinum may be weighed after about 10 minutes' cooling, porcelain after 20 minutes'. In all cases, the appropriate heat treatment should be repeated until no change in successive weighings is recorded. From the amount of weighed product, which is of known definite chemical composition, the quantity of the constituent sought may be calculated. Blank tests should be made on the reagents, as these may introduce small quantities of the particular constituent which it is desired to determine.

Electrolytic.—Under the influence of the electric current, the ions of a metallic salt in solution are set into motion; those of the metal are impelled in the direction of the current and flow towards the cathode where, given favourable conditions, they may finally be completely deposited as a coherent film of metal in a form suitable for weighing. Factors such as current density, time, temperature, hydrogen-ion concentration, nature of the electrodes and of the electrolyte must, however, all be taken into account.

Where readily applicable, electrolytic methods have much in their favour, especially their simplicity and cleanliness. Perhaps the most generally applied determination is that of copper, especially in its various alloys with zinc and tin; the solutions electrolyzed should be acid, though not too strongly so, with sulphuric or, more commonly, with nitric acid, this latter being used for the preliminary removal of tin. A rotating cathode of platinum gauze is the most convenient; the presence of a little hydrogen peroxide promotes the formation of a bright deposit, particularly from sulphuric acid solution. It is necessary to allow for bismuth which accompanies the copper. In solutions of the acidity required for deposition of copper, lead is completely deposited on the anode. If the quantity of lead is small, no great error is made

in considering the deposit as the dioxide; but should more than 2cg. of lead be present, the dioxide obtained may contain as little as 84% of lead, instead of the theoretical 86.6%. In such cases, or in any event if manganese also be present, the deposit should be dissolved from the anode, and converted into lead sulphate for weighing. Deposition of lead, however, from solutions containing a higher proportion of nitric acid than is permissible for copper, affords practically the correct dioxide.

Another useful electrolytic determination is that of zinc, especially in aluminium alloys of high zinc (12-14%) content. This is effected, after removal of copper, by electrolysis of the zincate solution, the aluminium being retained in solution by means of tartaric acid when the alkali is added. A gold rotating cathode is most convenient for this process; allowance must be made for traces of iron and manganese simultaneously deposited. The presence of chlorides, nitrates and ammonium salts is not permissible. In most other cases where electrolytic methods can be applied, preliminary separations by chemical means are necessary.

Volumetric Analysis.—The metric standard of volume, the litre, is the volume of 1kg. of pure water at the temperature of its maximum density, viz., 4° C., under standard barometric pressure; the one-thousandth part of this volume, the millilitre (ml.) is a convenient subsidiary standard which, it should be pointed out, is not identical with the cubic centimetre (cu.cm.). Actually 1 litre equals 1000.027 cu.cm., and although this difference is too small to be of practical importance, it is desirable from the point of view of strict accuracy that the term millilitre be generally adopted. Vessels marked "grm." or "gramme" are based upon the Mohr litre, which was taken as the volume of 1kg. of water as weighed directly in air at 15° C; the continuation of this system is not desirable, but in any case, such vessels may not be used in conjunction with those based on the true litre. 1 Mohr litre at 15° C = 1001.95ml.

Calibrated glassware for volumetric work should not be accepted as correct unless checked or supplied with a reliable certificate of calibration; otherwise an accumulation of errors may result in a difference of several units per cent. The usual vessels are the flask, pipette and burette; the first of these when filled at 15° C to the graduation on the neck contains a specified volume, from which aliquot parts may be withdrawn by means of pipettes. Finally, the standard solution is, in general, run out from the burette, usually graduated in millilitres and tenths, until by appropriate signs visible to the eye or by electrical means, to which reference is made below, the reaction is found to be complete. This procedure is termed "titration."

The usual volumetric processes may be broadly divided into three classes: (a) acidimetric and alkalimetric; (b) oxidation and reduction; (c) precipitation methods. The strength of standard solutions is commonly expressed in terms of normality; a normal solution is one which contains in one litre that weight of the reagent which corresponds to 1.008g. of hydrogen or its equivalent, having regard to the particular reaction involved. This weight is either the molecular weight, expressed in grams, or some simple fraction thereof.

According to Arrhenius's Ionic Theory, salts do not exist in aqueous solution entirely as such but are split up more or less completely into their constituents or "ions"; thus a solution of hydrochloric acid is regarded as containing hydrogen and chlorine ions H. and Cl', while sodium hydroxide exists in solution as Na. and OH'. The chemical reaction between these two bodies, $\text{HCl} + \text{NaOH} \rightarrow \text{NaCl} + \text{H}_2\text{O}$, is expressed ionically at $\text{H} + \text{Cl}' + \text{Na} + \text{OH}' \rightarrow \text{Na} + \text{Cl}' + \text{H}_2\text{O}$ or, by removing the terms common to both sides $\text{H} + \text{OH}' \rightarrow \text{H}_2\text{O}$. The hydrogen ion and the hydroxyl ion are characteristic of acids and alkalis respectively and, so long as one or other of these predominates, the solution is said to be acid or alkaline in reaction. Indicators are very weak acids or weak bases whose colours in the ionized and in the non-ionized state differ; constitutional alterations may also come into account. These colour changes occur within limited ranges of hydrogen-ion concentration, varying with the particular indicator, and it is upon this principle that the use of indicators in acidimetry and alkalimetry depends. Of those in common use, it may be said in general that

phenolphthalein should be used for the titration of weak acids with strong bases, and methyl-orange for weak bases with strong acids. Litmus and methyl-red are both sensitive to carbon dioxide; if these indicators are used when carbonates are present, it is necessary to expel the carbon dioxide by boiling. Bicarbonates react neutral to phenolphthalein; no indicator is suitable for the titration of weak bases with weak acids (*see* INDICATORS).

The numerous volumetric methods based on oxidation and reduction are often of considerable accuracy and ready application. Thus many metals form two (or more) series of salts differing in their degree of oxidation and which may be converted one to the other by means of appropriate oxidizing or reducing solutions of known strength. The oxidizing agents in most general use are potassium permanganate, iodine and potassium dichromate; others employed for more special purposes are potassium bromate, iodate and ferricyanide.

Solutions for oxidations with potassium permanganate and dichromate must be sufficiently acid; with the former the presence of sulphuric acid is preferable to that of hydrochloric acid, although the reducing effect of this on the permanganate is practically negligible in very dilute cold solutions, especially in the presence of manganous sulphate. With permanganate, the end point of the titration is readily observed by the lasting pink colour imparted to the solution; in the case of dichromate the end point may be noted by the use of an external indicator solution or preferably by using diphenylamine as an internal indicator. Iodine forms with starch a deep blue compound, which serves to indicate the presence of a very small quantity of the oxidizing agent; this reagent is used in conjunction with sodium thiosulphate, less frequently with sodium arsenite.

Solutions of reducing agents do not maintain their strength so well as oxidizing agents, but they may be preserved fairly well in a suitable apparatus in which air is replaced by an inert gas such as carbon dioxide. Stannous and chromous chlorides are used and more especially titanium trichloride or sulphate. These last are very powerful reagents of extensive application. In the precipitation methods of volumetric analysis, the standard reagent may be added until no further precipitation occurs, until a precipitate just appears, or until the end point is shown by means of an indicator, internal or external, with which a small excess of the reagent produces a characteristic change. The majority of the determinations in this category belong to the third type; thus chloride is titrated with silver using potassium chromate or fluorescein as indicator, silver with thiocyanate in nitric acid solution using a ferric salt as indicator.

The end point in volumetric work may also be found in many cases by *potentiometric* methods. These depend upon the fact that when a metal or hydrogen is brought into contact with solutions containing these same substances in the ionized state, a difference of potential is set up, the magnitude of which varies with the nature of the substances in contact and with the concentration of the ions in solution. As titration proceeds it generally happens that the potential difference, measured by suitable electrical means, undergoes a marked change at the end point, which may thus be determined. The method can be applied to acidimetric, reducing and oxidizing reactions, but in general holds little advantage over the older processes, the basic principle being the same in each case. The potentiometric method is, however, of especial value for the determination of hydrogen-ion concentration (*q.v.*), the importance of which in analytical as well as other work is becoming increasingly recognized.

Colorimetric Methods.—Colorimetric methods are of extreme value for the accurate determination of traces of certain substances, although interference may be caused by the presence of other compounds which develop colours with the reagent or which inhibit the required reaction. A comparison is made between tints developed from the test solution and those from a definite volume of a standard solution, the amount of which is adjusted until the colours are identical. By this method traces of bismuth may be estimated by reaction with potassium iodide; titanium with hydrogen peroxide; lead as sulphide; copper with ammonia or with ferrocyanide; iron with thiocyanate or with ferrocyanide;

FIG. 1.—APPARATUS FOR QUANTITATIVE ESTIMATION OF CARBON AND HYDROGEN IN AN ORGANIC COMPOUND
The principle depends on oxidizing a weighed quantity of the compound and then weighing the resultant dioxide and water

manganese as permanganate; ammonia with Nessler's reagent.

The most suitable methods for the estimation of any element will be found in the article devoted to that element.

ULTIMATE ORGANIC ANALYSIS

The limited number of elements (carbon, hydrogen, oxygen, nitrogen, sulphur, halogens and occasionally phosphorus and some metals) employed by nature in building up her vast store of organic compounds would suggest that the analyses of such substances are simple operations, and this is true in so far as the determination of the elements present, their relative proportions, and the molecular complexity of the compound are concerned. Naturally such information tells us nothing of the *structure* of the compound and, indeed, leaves us much in the same position as we should be in if we were interested in some building and were supplied with the builder's estimate for material while denied access to the architect's drawings and plans. The problem of determining the manner in which the elements present in organic compounds are arranged, important as it is, lies outside the scope of the present article, which is limited to the description of the ultimate analysis. With the exception of oxygen, all the elements present in organic compounds can be estimated readily; oxygen is nearly always determined by difference, and in view of this fact it is of great importance that a careful qualitative examination be made of a substance, otherwise the results of the quantitative analysis may be interpreted erroneously.

Qualitative Tests for the Elements.—*Carbon and Hydrogen.*—The organic nature of a compound is generally indicated by its behaviour on being heated in air; solids usually melt, then burn with a more or less smoky flame, leaving a black residue of carbon. To test directly for carbon and hydrogen, a small quantity of the material intimately mixed with about 20 times its bulk of dry copper oxide powder is heated in a dry test-tube closed by a cork carrying a delivery tube which dips into a solution of lime-water. The copper oxide is reduced, the hydrogen being oxidized

to water which bedews the cool part of the tube, and the carbon oxidized to carbon dioxide which forms a precipitate of chalk in the lime-water.

Nitrogen, Halogens, Sulphur.—When organic compounds containing any or all of these elements are heated strongly with metallic sodium they are decomposed with the formation of sodium cyanide, halide and sulphide, respectively (Lassaigne's test). To test for these elements, therefore, 1 mg. of the substance and a small pellet of sodium (or potassium) are heated in a narrow test-tube, gently at first and afterwards more strongly, until the glass softens; the hot tube is shattered by plunging it into water, which converts any residual sodium into sodium hydroxide, yielding an alkaline solution of the sodium salts, which is boiled and filtered, and the filtrate is used in the following tests:—

(a) Nitrogen.—A portion of the filtrate is mixed with a solution of ferrous sulphate containing a small quantity of the ferric salt and boiled, thereby converting any sodium cyanide present to ferrocyanide, which gives a bluish-green solution and a precipitate of Prussian blue on adding hydrochloric acid.

(b) Halogens.—A second portion of the alkaline filtrate is acidified with nitric acid and silver nitrate added, any precipitate of chloride, bromide or iodide, or a mixture of these, is examined in the usual manner. If the original substance contain also nitrogen or sulphur, the acid solution must be boiled to expel the hydrogen cyanide or hydrogen sulphide before adding the silver nitrate.

(c) Sulphur.—A third portion of the alkaline filtrate is tested for sodium sulphide (i.) by the formation of a deep violet colour when treated with a few drops of a freshly prepared solution of sodium nitroprusside; (ii.) by the evolution of sulphuretted hydrogen when acidified—this is readily detected by the odour and also by lead acetate test paper.

Phosphorus.—A small portion of the organic compound is intimately mixed with about ten times its bulk of a mixture of sodium carbonate and peroxide (2:3) and heated to fusion in a nickel crucible. The cold water extract of the melt is filtered, acidified with nitric acid, and tested for phosphoric acid with ammonium molybdate.

Metals.—(i.) Volatile metals. (a) Arsenic.—The presence of arsenic in an organic compound is usually revealed by the formation of a dull grey mirror of the metal on the walls of the test-tube when the compound is fused with sodium as in Lassaigne's test. (b) Arsenic and Antimony.—A small quantity of the compound is fused with a mixture of sodium carbonate and peroxide as in the test for phosphorus. The fused melt is extracted with water, acidified and tested with sulphuretted hydrogen. (c) Mercury.—

FIG. 2.—APPARATUS FOR ABSOLUTE METHOD (DUMAS) OF ESTIMATION OF NITROGEN IN AN ORGANIC COMPOUND
A known weight of the compound is heated with copper oxide in a current of carbon dioxide; the nitrogen evolved is collected over a strong solution of potassium hydroxide and then measured in a eudiometer tube

When an organic compound containing mercury is mixed with soda lime and heated in a long test-tube, a mirror of metallic mercury is formed.

(ii.) Non-volatile Metals.—Any of these metals that may occur in organic compounds are found as such or in the form of their carbonate or oxide in the ash left after the compound has been ignited on porcelain or silica. The ash is dissolved in dilute hydrochloric acid and the solution examined for metals in the usual manner (see section on "Inorganic Analysis").

Quantitative Analysis of Organic Compounds.—*Estimation of Carbon and Hydrogen.*—The carbon and hydrogen in an organic compound are estimated by completely oxidizing a weighed quantity of the substance and weighing the carbon dioxide and water thus formed. The simple method devised by Liebig in 1831 for carrying out this operation is in all essential principles the one still employed. A weighed quantity of the substance is heated in a tube filled with dry copper oxide, and the water and carbon dioxide are absorbed in weighed tubes filled with dried calcium chloride and potassium hydroxide solution or soda lime respectively. A current of dry air or oxygen is passed through the tube to sweep the products of combustion into the absorption apparatus. Fig. 1 shows the essential details of the apparatus required for these estimations; *a* and *b* are closely fitting, short spirals of copper gauze which serve to hold the copper oxide in position; the copper oxide is prepared by oxidizing copper wire; *c* and *d* are longer copper oxide spirals; *f* is the platinum or porcelain boat containing the weighed quantity of the compound.

In the absorption apparatus, the water is collected in the glass stoppered U-tube *g*, filled with calcium chloride (carefully freed from lime). The carbon dioxide is absorbed by the soda-lime contained in the U-tubes *h* and *h*¹, the second limb of each tube containing a short filling of calcium chloride. The two soda-lime tubes may be replaced by the apparatus *k*, of which the bulbs are charged with concentrated potassium hydroxide solution and the side tube filled with soda-lime and calcium chloride. The apparatus for purifying the current of air or oxygen is connected with the anterior end of the tube and consists of a series of washing cylinders charged with potassium hydroxide or sulphuric acid, and U-tubes filled with soda-lime or calcium chloride to remove moisture and carbon dioxide from the incoming gas. This apparatus is arranged in duplicate, one for the air and one for the oxygen supply. Any simple form of gas-heated furnace may be employed (fig. 2), or the tube may be heated electrically.

The combustion tube and its copper oxide charge are dried by heating the tube to a dull red heat for about an hour while a cur-

rent of dry air is passed, the posterior end of the tube being protected by a calcium chloride tube. At the end of that time the fore part of the tube containing the oxidized spiral and the first six inches of copper oxide is cooled. While this process is in operation, the weighings are made. About 0.2 gr. of the pure dry compound to be analysed is weighed into the platinum or porcelain boat if the compound is a solid or a non-volatile liquid. Volatile liquids are weighed in small thin glass bulbs drawn out to a capillary opening. The tubes for collecting the water and carbon dioxide are also weighed, and attached to the posterior end of the combustion tube. The boat and its contents are then introduced into the cooled anterior end of the combustion tube.

A slow current of air is passed through the tube, and the burners under the oxidized spiral in the rear of the boat are lighted. The heating is gradually extended towards the boat by moving forward the heated screen over the tube, or increasing the flame surface under the tube, the object being to distil the contents of the boat, or the volatile products of decomposition, on to the cold copper oxide where the combustion is completed. This most critical part of the operation must be carried out very slowly, and is finally completed in a current of oxygen which burns any residue of carbon left in the boat, and re-oxidizes the reduced copper oxide. After displacing by air the oxygen in the apparatus, the absorption tubes are removed, closed, cleaned and allowed to cool in the balance room before being re-weighed. From the weight of carbon dioxide and water yielded by the definite weight of the compound, the percentages of carbon and hydrogen in the compound are readily calculated.

The simple method described above applies to compounds containing carbon, hydrogen and oxygen only; if elements other than these are present the filling of the tube must be modified as follows: (*a*) *Nitrogen present.* The copper oxide spiral (*d*) is replaced by a similar spiral of freshly reduced copper to reduce any oxides of nitrogen that may be formed during the combustion. It is introduced into the end of the tube that has been previously cooled, before attaching the absorption apparatus. (*b*) *Halogens, sulphur or arsenic present.* The first six inches of copper oxide after the boat are replaced by a lead chromate cartridge, made by filling a hollow cylinder of copper gauze with freshly ignited fused lead chromate. The copper container becomes oxidized in the preliminary heating of the tube, non-volatile lead compounds being formed with the sulphur or arsenic in the compound, and sparingly volatile compounds with the halogens. A short spiral of silver gauze should, therefore, be introduced at the posterior end

of the tube when the compound contains halogens.

Estimation of Nitrogen.—The two methods in use for the estimation of nitrogen are (a) the absolute method (Dumas), in which the nitrogen in a known weight of the compound is eliminated in the gaseous form and estimated by direct measurement; (b) the Kjeldahl method, in which the nitrogen in a known weight of the material is reduced to ammonia and estimated volumetrically by titration. (a) The absolute method consists in the complete oxidation of a known weight of the compound by heating it with copper oxide in a tube in a current of carbon dioxide, passing the gaseous products of combustion over a heated copper spiral and collecting the nitrogen in a gas burette over strong potassium hydroxide solution. The gas is afterwards transferred to a calibrated eudiometer tube and measured over water. The method of filling the tube is indicated in fig. 2. The three grades of coarseness in the copper oxide used are obtained by crushing the ordinary copper oxide made from wire, and passing it through two copper gauze sieves, 20 strands and seven strands to the centimetre respectively; the first retains the coarse and medium grades, and the second the coarse. The amount of the substance used in an analysis should be sufficient to give about 20 cu.cm. of nitrogen. The charged tube is placed in the furnace and connected with an apparatus for generating carbon dioxide, and with a Schiff's nitrometer filled with a concentrated solution of potassium hydroxide. While the air in the apparatus is being displaced by carbon dioxide, the part of the tube containing the coarse copper oxide and reduced spiral is heated to dull redness. When no insoluble gas collects in the charged nitrometer, the current of carbon dioxide is stopped, and the nitrometer is filled with the potassium hydroxide solution which is allowed to overflow into the thistle funnel seal attached to the end of the capillary transferring tube. The burners under the copper oxide spiral are then lighted, and when this part of the tube is at a dull red heat the heating is extended towards the mixture of the substance with copper oxide, and so regulated that not more than three bubbles of gas are ascending the nitrometer tube at the same time. Finally, when all the burners are lighted, the tube has attained a uniform dull red heat, and there is no further evolution of gas, a slow current of carbon dioxide is again passed through the tube to sweep out the remainder of the nitrogen. The nitrometer is then removed, the gas reduced to atmospheric pressure, by bringing the liquid in the open arm of the nitrometer to the same level as that in the closed arm, and after about 15 minutes transferred to a eudiometer tube over boiled-out water, which is then completely immersed in a tall glass cylinder of water containing also a thermometer. After about ten minutes the volume of the nitrogen (v) the temperature (t) and the barometer (p) are read. If p' is the tension of aqueous vapour under these conditions and w denotes the weight of substance taken, the percentage of nitrogen in the compound is given by the expression

$$N = \frac{v}{w} \times \frac{273 \times (p - p') \times 0.12507}{(273 + t) \times 760}.$$

(b) The Kjeldahl method is a modification of Will and Varrentrapp's method and is used for the estimation of nitrogen in such materials as foodstuffs, therapeutic substances, fertilizers, etc., in which the amount of nitrogen is small and many determinations have to be carried out simultaneously and rapidly. The method consists in decomposing the organic material by heating it with concentrated sulphuric acid; the carbon is oxidized and the nitrogen converted to ammonia which is retained as the sulphate, and afterwards estimated in the usual manner by distillation (see AMMONIA). A weighed quantity of the material (0.5 to 5.0 gr.) is placed in a long-necked, pear-shaped flask of 500 cu.cm. capacity, 20 cu.cm. of concentrated sulphuric acid are added, the flask is clamped in an inclined position and the contents heated gradually to avoid frothing. After the acid has been boiling for about 15 minutes, 10 gr. of potassium sulphate are added, and the heating is continued until the contents of the flask are clear and a faint straw colour. In cases of not easily oxidizable materials, small quantities of certain metallic salts such as copper or mercuric sulphate or mercurous iodide may be added. Finally the cold acid liquid is transferred, with the washings of the flask, into

the distilling flask of an ammonia distillation apparatus; after the contents of the flask have been made alkaline, the ammonia is distilled into a measured volume of standard sulphuric acid and estimated by titrating the excess of acid.

The Kjeldahl method can also be applied to the analysis of pure organic compounds, provided that those compounds which contain nitrogen combined directly with oxygen or with nitrogen as in nitro-, nitroso-, azo- or diazo-compounds or hydrazines, undergo a preliminary reducing operation.

Estimation of Halogens.—The estimation of halogens involves the complete decomposition of the compound, with the conversion of the halogen element into the hydracid or one of its salts, which is subsequently precipitated and estimated as the silver salt. (a) Liebig's is the oldest method and the one applicable to the largest number of organic compounds. It consists in decomposing a weighed quantity of the compound by heating it to redness with a large excess of pure lime in a glass tube sealed at one end, plunging the hot tube into cold water, dissolving the lime and calcium halide in cold dilute nitric acid, filtering, and estimating the halogen acid in the filtrate in the usual manner. Piria and Schiff modified the method in the direction of shortening the time of the operation, by replacing the lime by a mixture of lime and sodium carbonate, and the glass tube by two nickel crucibles, the smaller one containing the mixture of the substance being inverted in the larger, and the annular space between the two filled with the lime and sodium carbonate mixture. (b) Stepanoff's method, as modified by Bacon, is applicable to compounds in which the halogen is readily eliminated as hydracid by hydrolysis or by reduction. It consists in heating a weighed quantity of the compound with sodium and alcohol, and estimating the sodium halide in the resulting solution. (c) The method of Carius, as modified by Kuster, is the one most generally employed; it consists in the destructive oxidation of a weighed quantity of the compound (about 0.2 gr.) by means of fuming nitric acid (2 cu.cm.) in the presence of silver nitrate in a sealed tube at a temperature of 250°–270° C. The halogen is converted into the silver salt and weighed as such.

Estimation of Sulphur.—The estimation of sulphur in organic compounds involves the destructive oxidation of the substance whereby the sulphur is converted to sulphuric acid and weighed as the barium salt. The two methods in general use are:—(a) The method of Carius, in which the operation is carried out as in the preceding case, no silver nitrate is required, but as the oxidation is facilitated by the presence of a small quantity of bromine, a crystal of potassium bromide is placed in the tube containing the compound. The contents of the tube are diluted with water, the nitric acid removed by evaporation and the sulphuric acid precipitated and weighed as the barium salt. (b) The method of Asboth, in which the oxidizing agent employed is a mixture of sodium peroxide (three parts) and sodium carbonate (two parts). A weighed quantity of the substance (0.2 to 0.5 gr.) is mixed with about 15 gr. of the oxidizing mixture in a nickel crucible which is then carefully heated until the contents become liquid. When cold, the melt is extracted with water, and the soluble sulphate estimated in the usual manner.

Estimation of Phosphorus.—Organic compounds containing phosphorus are oxidized by fuming nitric acid, by concentrated nitric acid and potassium permanganate, or by chromic and sulphuric acids. The resulting phosphoric acid is precipitated as ammonium phosphomolybdate, and subsequently weighed as magnesium pyrophosphate.

Estimation of Metals in the Salts of Organic Acids and Bases. Gold, silver and platinum in organic salts are weighed as the metallic residue left after the organic material has been destroyed by igniting a weighed quantity of the dry salt in a platinum or silver crucible. Sodium, potassium, barium and calcium salts are decomposed by igniting a weighed quantity of the dry salt in the presence of pure sulphuric acid and weighing the sulphate of the metal.

Modern Modifications.—The methods described for the ultimate analysis of organic compounds leave nothing to be desired on the score of simplicity and accuracy, but many of them are

very tedious in operation, and the modifications that have been introduced aim at reducing the time required for the analysis. The earlier attempts were directed towards the employment of more vigorous oxidizing agents than copper oxide, and of these the use of oxygen in the presence of a contact substance (Kopfer, 1876) has been employed with singular success by Dennstedt. He uses a platinum contact material, heated to bright redness, and passes the vapour of the substance over it in a rapid stream of oxygen. The carbon dioxide and water are collected and weighed in the usual manner. If the compound contains nitrogen, chlorine, bromine or sulphur, a boat containing lead peroxide heated to 320° C is placed in the rear part of the combustion tube; this serves to break up any oxides of nitrogen that may be formed, and at the same time to absorb quantitatively the chlorine, bromine or sulphur, which can be estimated subsequently by the usual gravimetric methods. If iodine be present this can be retained by molecular silver contained in a second boat placed in the rear of the first.

Later modifications have aimed at reducing the time required for a combustion by a corresponding reduction in the amount of material analysed and the magnitude of the apparatus employed, and the micro-analytical methods devised by Pregl, Dubsky, Funk and others are now fairly extensively employed in schools of organic research. Using 5–15mg. of the substance, a carbon and hydrogen estimation can be completed within an hour.

H. ter Meulen and his school have recently described new methods for the ultimate analyses of organic compounds which include the direct estimation of oxygen. The analyses are carried out by the combustion (oxidation), or the destructive hydrogenation method, usually with the help of catalysts. The operations can be conducted with great rapidity, as about 50mg. of the compound are employed in each estimation, and many of the final operations are volumetric instead of gravimetric. Thus nitrogen is reduced quantitatively to ammonia and estimated by titration; the halogens are reduced by hydrogen containing ammonia to the ammonium halide and estimated volumetrically by the Volhard method.

GAS ANALYSIS

The general principles involved in the various processes of gas analysis are best exemplified by a consideration of the quantitative estimation of the constituents of fuel gases, such analytical tests being the chief task of gas examiners. Gasometric methods are, strictly speaking, branches of *volumetric* analysis, one of the main divisions of quantitative work.

The composition of a gas is usually expressed in percentages by volume, as it is easier to measure a gas than to weigh it. As, however, the volume of a gas depends upon its temperature, pressure and moisture content, all volumes must be compared at the same temperature and pressure and further must be either dry or fully saturated with moisture; if the conditions under which they are compared are not the same, the volumes in each case must be referred to a standard condition. The standard usually employed is the International Standard, in which all volumes are referred to the dry volume which the gases would occupy at 0° C and 760mm. of mercury pressure. If V is the volume of a gas saturated with moisture measured at t° C and h mm. of mercury, and a is the vapour pressure of water at t° C (obtained from tables), then the volume V_0 at the standard conditions is given by the equation $V_0 = V(h-a)273/760(273+t)$. In Great Britain the gas industry is bound by statute to use a different standard, namely the volume saturated with moisture at 60° F and 30in. of mercury pressure. Thus if V is the volume at t° F and h in., the vapour pressure of water at t° F being a , then the volume under standard conditions is $V_0 = V(h-a)17.64/(460+t)$. Tables to facilitate these calculations are given in text-books of gas analysis.

The volumetric analysis of a gas is usually carried out on a

small quantity, ranging from 5 to 100 cu.cm., and if this small sample is to be representative of a large bulk of gas, special precautions must be taken to ensure that the sample is properly taken. Whenever the analysis of a sample of gas cannot be made at the place where it is collected, it must be stored in a sample tube with well-fitting glass taps. If the sample is to be kept for some time, it is preferably preserved in a glass tube with sealed ends.

The methods employed in the volumetric analysis of gases are based on: (1) Successive absorption of the constituents by suitable reagents each of which absorbs one only; (2) burning the gas with air or oxygen and measuring the change in volume and the amount of carbon dioxide produced; (3) selective oxidation by passing the gas over suitable reagents; e.g., heated copper oxide.

The following are typical analyses of fuel gases:

| | CO ₂ | Unsaturated hydrocarbons | O ₂ | CO | H ₂ | CH ₄ | N ₂ |
|----------------|-----------------|--------------------------|----------------|------|----------------|-----------------|----------------|
| | % | % | % | % | % | % | % |
| Coal gas | 2.8 | 3.7 | 0.5 | 9.3 | 44.1 | 33.2 | 6.4 |
| Water gas | 4.8 | .. | 0.4 | 37.9 | 49.2 | 3.0 | 4.7 |
| Producer gas | 9.9 | 0.3 | 0.3 | 20.0 | 17.8 | 2.8 | 48.9 |
| Waste flue gas | 11.3 | .. | 7.0 | 1.0 | 0.8 | .. | 79.9 |

Of these constituents carbon dioxide (CO₂), unsaturated hydrocarbons (which include ethylene, propylene and benzene), oxygen (O₂) and carbon monoxide (CO) are estimated by absorption methods; and hydrogen (H₂), methane (CH₄) and sometimes carbon monoxide by combustion methods. The nitrogen is usually obtained by difference.

The absorbents used are (1) 25% aqueous solution of caustic potash for carbon dioxide; (2) bromine water or fuming sulphuric acid for unsaturated hydrocarbons. In either case these reagents must be followed by an absorption with potash to remove vapours evolved by bromine and sulphuric acid; (3) stick phosphorus or a solution of potassium pyrogallate (10g. of pyrogallic acid dissolved in 100 cu.cm. of saturated caustic potash) for oxygen; (4) acidic or ammoniacal cuprous chloride solution for carbon monoxide—the latter is preferable and is made by mixing 1vol. of ammonia (sp.gr. 0.905) with 3vol. of a solution containing cuprous chloride 200g., ammonium chloride 250g., water 750g. Two absorptions must be made with the cuprous chloride solution, the last one being with a fresh solution. Alkaline pyrogallate and cuprous chloride solutions, which become oxidized and lose their absorbing capacity when exposed to the air, must be stored in the double type of pipette if the Hempel apparatus is being used, the two exterior bulbs being filled with water to prevent access of air.

Certain reagents will remove more than one constituent from the gas so that the order in which the absorptions are made is very important. If the unsaturated hydrocarbons are to be removed by bromine water, the sequence is as follows: carbon dioxide by potash, unsaturated compounds by bromine, oxygen by phosphorus or pyrogallate, carbon monoxide by cuprous chloride. On the other hand, if fuming sulphuric acid is used in place of bromine the order must be: caustic potash, pyrogallate (not phosphorus), fuming sulphuric acid, cuprous chloride. Phosphorus will not remove oxygen from the gas if unsaturated compounds are still present; it is also very slow in action if the temperature of the gas falls below 18° C.

The contraction observed and the carbon dioxide produced when hydrogen and methane are burned together with a known excess of oxygen or air, give a means by which these two gases may be determined, whereas the residual nitrogen is estimated by difference.

When burned with an excess of air or oxygen, 1vol. of hydrogen combines with $\frac{1}{2}$ vol. of oxygen to form water, which is condensed;

so that there is a contraction of $1\frac{1}{2}$ vol.: $\text{H}_2 + \frac{1}{2}\text{O}_2 = \text{H}_2\text{O}$. With methane the reaction is $\text{CH}_4 + 2\text{O}_2 = \text{CO}_2 + 2\text{H}_2\text{O}$, i.e., 1 vol. of methane combines with 2 vol. of oxygen, forming 1 vol. of water vapour (which is condensed) and 1 vol. of carbon dioxide; the contraction is therefore 2 vol. and the carbon dioxide produced is equal in volume to the methane present. When a mixture of the two gases is burned, the methane is A and the hydrogen $\frac{2}{3}(C-2A)$, where C is the contraction on burning or exploding and A is the volume of carbon dioxide formed.

Of the many forms of gas apparatus recommended for these analyses three will now be described in detail—the Hempel apparatus as a type in which the volume of the gas is measured at constant pressure, the Bone and Wheeler apparatus as an example of those in which the pressure of the gas is measured at constant volume and the Haldane apparatus, employed when some of the important constituents are present in very small amounts.

The Hempel Apparatus (fig. 1) consists of a cylindrical glass measuring burette which holds 100 cu.cm. and is graduated in $\frac{1}{2}$ cu.cm. This tube is surrounded by a water-jacket so that a uniform temperature is maintained during analysis; the pressure is kept constant by always taking the measurements under atmospheric pressure which is assumed not to vary while the analysis is being made. The measuring vessel is connected by rubber tubing to a levelling tube or bottle. Slightly acidified water is poured into the levelling tube and the burette is completely filled by opening the tap at the top and raising the levelling tube, the tap being then closed. The gas to be analysed is drawn into the burette by connecting the top to the sampling tube, opening the top tap and lowering the levelling tube. When sufficient gas has been drawn into the burette, the tap is closed and the volume read, care being taken that the levels of the water in the burette and levelling tube are the same. This ensures that the volume of gas has been measured under atmospheric pressure. The pipette

FIG. 1.—HEMPEL BURETTE AND LEVELLING TUBE

(fig. 2) containing the appropriate absorbing liquid is then connected to the top of the burette by a glass capillary tube bent twice at right angles. The liquid in the pipette must have been previously brought to the top of the capillary portion of the pipette and the bent tube must be full of water so that air does not enter the burette in the subsequent operations. The gas is driven into the pipette by opening the tap and raising the levelling tube, and is gently shaken whilst in contact with the liquid; when the absorption is complete, the gas is drawn back into the burette and measured with the water at the same level in the burette and levelling tube. The loss in volume is the amount of the particular constituent absorbed by the reagent. The operations are then repeated in a similar manner with the other absorbers. The absorptions are usually complete after two or three minutes.

FIG. 2.—HEMPEL PIPEPETTE FOR ABSORPTION OF GAS IN APPROPRIATE LIQUID

Hydrogen and methane are estimated in the residual gas by diluting 15 or 20 cu.cm. to 100 cu.cm. with excess of air or oxygen and exploding the mixture under reduced pressure over mercury in the explosion pipette. This pipette (fig. 3) is provided with a pair of platinum sparking points which are connected to a small induction coil, and the reduction of pressure is effected by lower-

ing the mercury reservoir which is connected by thick-walled rubber tubing to the pipette. The gas is then returned to the burette and the contraction measured. The carbon dioxide formed is absorbed in the potash pipette and this second contraction measured. The hydrogen and methane present in the small amount of residual gas taken for the explosion can be calculated from the formulae given above, and hence the percentages in the original gas are calculated.

The combination of hydrogen, methane and oxygen can be effected without explosion by passing them at a suitable dilution

FIG. 3.—HEMPEL EXPLOSION PIPEPETTE

into a pipette filled with mercury provided with a short length of platinum wire which can be heated by passing an electric current from dry cells or an accumulator.

Hydrogen can be determined in the presence of methane by passing a mixture of the gas and air through a capillary tube containing palladium wire or palladium-asbestos. The gas is passed several times backwards and forwards from the burette through the gently heated tube into a pipette containing water.

The nitrogen remaining is often determined by difference, but it is advisable to check it by a more direct method. For this purpose a fresh sample of the gas is circulated through a silica tube filled with copper oxide heated to bright redness, and is passed into a pipette filled with caustic potash solution. The whole of the

FIG. 4.—THE ORSAT APPARATUS FOR ANALYSIS OF FLUE GASES

This apparatus, being movable, can be transported to a boiler house or similar place and the analysis of waste gas made there without the delay of taking samples to a laboratory

gases present with the exception of the nitrogen are burned to carbon dioxide and water, both of which are absorbed in the potash. The operations are continued until the volume of the residual gas is constant, and a correction is applied for the air originally contained in the silica tube.

The Hempel apparatus is not portable, but a modification known as the Orsat apparatus (fig. 4) is portable. This resembles the Hempel in principle and use except that the pipettes are permanently attached to the burette by a glass capillary tube and taps. When the apparatus is intended for the analysis of flue gases only,

three pipettes are provided filled with caustic potash, alkaline pyrogallate and cuprous chloride, respectively. A bromine pipette and a palladium-asbestos tube are sometimes added. The carbon monoxide found will always be too low as only one pipette is employed for the cuprous chloride.

It has been assumed up to the present that the gases analysed are completely insoluble in water; and with the exception of carbon dioxide, which is appreciably soluble, the assumption is correct enough for ordinary purposes. To avoid loss of carbon dioxide, the water is often saturated with the gas to be analysed; or for more accurate work the water is replaced by mercury. The Sodeau apparatus is based on the same principle as the Hempel arrangement but employs mercury.

In the methods so far described the volume of the gas has been measured at a constant pressure and temperature. The alternative principle of measuring the gas at a constant volume and temperature can be equally well employed. This method has the advantage that 5 or 10 cu.cm. of gas can be expanded to give a pressure of roommm. and that all the measurements are independent of the barometric pressure.

The Bone and Wheeler Apparatus.—This is the principle of the well-known Bone and Wheeler instrument which, as shown in fig. 5, consists of a glass U-tube AB connected at the bottom by

FIG. 5.—BONE AND WHEELER APPARATUS FOR MEASURING GAS AT A CONSTANT VOLUME AND TEMPERATURE

thick-walled rubber tubing to the mercury reservoir D, the latter being raised and lowered by the winch. The U-tube is surrounded by a waterjacket through which water at a constant temperature is circulated. The limb B is graduated in mm., the limb A is marked by a series of constant-volume marks, each coinciding with a roommm. mark on the pressure limb B (*i.e.*, with 0, 100, 200mm., etc.). B is closed at the top with a glass cock, attached with rubber tubing and wired on. A is connected by capillary tubing through various glass taps to the explosion tube E and the laboratory vessel F, which is open at the bottom and sealed with

mercury in the trough G. The tap L also affords a passage to the waste bottle, which in turn is connected to a water-pump so that the contents of F can be removed from the apparatus. The explosion tube E is fitted with platinum sparking points at the top end and is provided with a separate mercury reservoir. The whole apparatus is first filled with mercury and all the taps closed; both tubes A and B are moistened with dilute sulphuric acid to ensure

FIG. 6.—HALDANE APPARATUS FOR ANALYSIS OF MINE AIR

This enables the amount of choke-damp or fire-damp in the mine air to be determined very accurately. If the proportion of oxygen in the air is also required, a third pipette, filled with alkaline pyrogallate, is used

both being saturated with moisture and to avoid fouling with alkaline solutions. Reservoir D is lowered and the lower tap opened so that a vacuum is produced in A and B. The lower tap is closed and the apparatus tested for tightness by seeing that the levels of the mercury in A and B remain the same, even when all the taps are opened back to the one closing the exit to the laboratory vessel F. Gas is then admitted either through M or under the mercury in F; by raising or lowering D the level of the mercury is adjusted to one of the constant volume marks. The level of the mercury in B is then read and the difference between the levels of A and B will give the pressure of the gas in mm. of mercury. A few cu.cm. of the absorbent is placed in F, using a pipette with a curved tip for the purpose. The gas is then driven into F, gently agitated in contact with the absorbent until the removal of the constituent is complete, drawn back into A and the level of the mercury adjusted to the same constant level mark as at the start. The difference in the mercury levels now observed subtracted from the previous difference represents the amount of the gas absorbed, and the ratio of the two differences is the proportion of the constituent. The liquid in F is then drawn off to the waste bottle. All the operations are performed by raising or lowering D with the necessary manipulations of the taps. When necessary the absorbents are completely washed from F by 5% sulphuric acid. The hydrogen and methane are determined by explosion under reduced pressure with an excess of oxygen. The mixture in the tube A is passed into the explosion tube and fired by a spark. The subsequent operations are much the same as described in the Hempel method.

The Haldane Apparatus.—The portable form (fig. 6) is commonly employed for the analysis of mine air. This air in addition to oxygen and nitrogen may contain more carbon dioxide than is present in clean air, and may be contaminated with small amounts of carbon monoxide, hydrogen and methane. The determination of these constituents is of the utmost importance in connection with the safety of mines. Mercury is used as the confining liquid in a burette so constructed that small differences of volume can

be accurately measured. This is attained by making the lower portion of the burette of much smaller diameter than the upper. The temperature and pressure of the gas are made to balance that of a constant mass of gas contained in a compensating tube. This tube is similar in shape and capacity to the burette and is placed at its side in the same water-jacket. Pipettes are provided for removing carbon dioxide and oxygen by potash and pyrogallate respectively. The mine air is first passed into the potash pipette to remove the carbon dioxide, the combustible constituents are burned by passing the residue into the slow combustion pipette and burning them by the agency of a white hot platinum wire. The contraction, carbon dioxide formed, and oxygen remaining are determined. The oxygen present in the original gas is determined separately. From these figures the amounts of carbon monoxide, hydrogen and methane can be calculated.

CHEMISTRY, APPLIED. Applied chemistry refers to the use made in other sciences and arts of data which have been established through chemical research. An absolutely sharp distinction between pure and applied chemistry, so-called, is well nigh impossible. The difficulties encountered in each class of work are comparable, and the ability demanded for success is equal in the two cases. The methods differ, but the principal difference is in the scale of operations and in the immediate objective. Not only do larger masses as encountered in industry involve changes in the prescribed temperature, time and concentrations, but the equipment can seldom be made of the same materials. For pure research we may draw upon platinum, quartz, alloys as may be required and laboratory glassware. In industry there must be substituted wood, iron, steel, concrete, ceramic products, alloys and other well-known and important materials of great size and strength. Often the greatest difficulty is encountered in selecting suitable apparatus for the plant, bearing in mind length of life and commercial economy. A striking example is the recently perfected method for the manufacture of nitric acid by the oxidation of ammonia, thereby displacing Chilean nitrate as a raw material for this important acid. The perfection of chrome steel and chrome iron has made possible the economic operation of this process. Application of the research in this case awaited the production of these alloys.

C. F. Kettering has said that pure science involves getting facts when they are not needed, while applied science is obtaining these facts when they are wanted, sometimes most urgently. R. A. Millikan believes that all research, to be justified, must ultimately be useful. The attitude of a generation or two ago, when researchers expressed the hope that their work might never become useful and that science might always remain pure, has materially changed, due in some degree to the recognition on the part of industrialists of the vital importance of pure or fundamental research.

It is in applied chemistry that the public has the greatest interest, for it measures the value of scientific work by commercial products which it may enjoy and by other results which appeal to the aesthetic sense and make for creature comforts. The contributions of chemistry are seldom recognized by the ultimate consumer, for their identity has become lost. The achievements of most sciences are more readily comprehended by the non-technical public and it is only within a decade that efforts have been made to remedy the situation. To-day a larger proportion of the public recognizes the relations of chemistry to all activities of modern life, and without claiming for that science too large a share of credit, it may be conservatively said that with physics and mathematics chemistry occupies a fundamental place in the scheme of things.

In industry uniform results are obtained only with raw materials of constant quality within established limits. The simplest application of chemistry has to do with the analysis of these raw materials to ascertain whether they can be used to advantage, and

particularly to guard against certain impurities or interfering substances which if present might result in the production of unprofitable seconds or in unsalable merchandise. Analytical chemistry is the basis of plant control and at many stages in manufacture must be relied upon for the guidance of operations. This is true in the manufacture of sugar and in the production of steel, where the molten metal is often held awaiting the report of the chemist before pouring. Obviously the analyst must work at top speed. In other cases samples of ores are rushed to the laboratory, that analysis may be made while the cars are in transit, so that proper proportions may be chosen upon arrival. Another familiar application of analytical chemistry in industry is the check upon finished work which forms the basis of guarantees, particularly where goods are bought on specification or which, though finished, are semi-manufactured products for some other purpose.

Not forgetting that analytical chemistry, which tells how much of various materials are present, underlies all chemical work, attention may be directed to more difficult industrial applications. Success in the utilization of by-products and the elimination of waste in industry are two classical examples of applied chemistry. The employment of by-products has led many a manufacturer into an entirely new line. Thus, a New England lumbering firm took up the manufacture of pulp. The installation of a plant to manufacture their own bleach gave hydrogen as a by-product, and this latter was used for the hydrogenation of oil to produce hard fat for cooking purposes. Further balancing of plant operations has led this firm into a dozen chemical fields, in all of which it has become a factor of recognized importance.

Organic Synthesis.—Of particular significance is organic synthesis in industry, for this is a field from which have come the most familiar chemical products of the day. These include dyestuffs, the medicinals, flavours, perfumes, photographic chemicals, disinfectants, cosmetics, etc., from coal-tar products, and an amazing list of synthetic organic materials of non-coal-tar origin. When it is remembered that in all this work the chemist is dealing with molecules and atoms that no one has ever seen and that from them millions of pounds of identical compounds are made annually, some appreciation will be had of the accomplishment. As knowledge has increased concerning the structure of molecules, ways have been devised for attaching atoms in various places, substituting whole groups of atoms for those already present and otherwise changing the molecule to give a product of desired characteristics. Many things desired remain to be accomplished and indeed the scientist almost despairs when he realizes the profundity of his ignorance. But this is due to the appreciation of what is possible, and there is every reason to believe that greater progress will be made in future.

The reduction of costs, elimination of waste, utilization of by-products, improvement of processes and development of entirely new products, indicate something of applied chemistry in industry. Difficult as these applications frequently are, it is when we consider chemistry as an ally of medicine and surgery that our admiration is most excited. The extremely delicate balance which characterizes the human body, the multiplicity of chemical reactions constantly in progress in the cells of the body, and the lack of positive knowledge concerning these body processes enormously complicate the situation which confronts chemistry applied to medicine. Beginning in many cases with natural remedies long used for various cases of illness, the chemist's first contribution has been the purification and standardization of these naturally occurring active principles. This in itself has been a noteworthy accomplishment and in several cases has been followed by the synthesis of the active principle, yielding a compound of far greater usefulness. Some specifics like chaulmoogra oil could be used only with the greatest difficulty but a soluble salt made in the laboratory from the acids contained in the oil provided a remedy of the greatest promise in combating leprosy. The physician now has at his disposal a long list of synthetic compounds nowhere found in nature, which not only permit a varied attack upon some diseases but offer for the first time in history specifics for certain ailments.

Medicine to-day, while not discarding the alliance with biology, generally recognizes that the greatest hope of the future lies in a chemical approach to a study of the human body and its diseases. Applied chemistry has shown, for example, the importance of knowing not only the type of food used but the products of this food in the alimentary tract. Perfected methods of determining sugar in the blood were the forerunner of insulin, itself separated from the pancreas, purified, and standardized for the relief of thousands of diabetics by methods based on chemistry. Indeed some regard the chemistry of the ductless glands and a chemical knowledge of the hormones as the next important step in the development of medical science. Surgery has also had its contributions. Anaesthetics, both old and new, are chemical compounds, the preparation of which involves the utmost care to insure purity. The methods upon which asepsis is based rest solidly upon a foundation of applied chemistry and the great decrease in the number of deaths following operations is in no small degree due to the availability of chemical compounds used as antiseptics and germicides.

Chemistry also has a share in the perfection of special steels and alloys (*q.v.*) for surgical instruments and the various equipment of the operating room. The ceramic chemist provides the enamelled metalware, the glass and the tiles. The chlorine effective in the Carrel-Dakin solution is the same as that used by the textile chemist for the bleaching of the textiles—and so one might run through the whole list of equipment and appurtenances.

Chemistry in Agriculture.—Applied chemistry has not overlooked agriculture. Intensive crop production depends upon fertilizers, which may still be considered in a formative period of development, notwithstanding their long use in enormous quantities. While potassium, phosphorus and nitrogen are still recognized as the principal plant foods, knowledge is being acquired as to the importance of traces of many other chemical elements in plant and animal metabolism. But for the insecticides and fungicides, all of them chemical compounds, we should face the problem of greatly diminished food supplies, if indeed we were able to avoid the threat of famine from time to time. Not only may yields be increased and the harvest preserved through applied chemistry, but recent work has shown that the dormant period of some tubers can be shortened by chemical means. Potatoes, which ordinarily require several weeks' rest between harvest and seed time, may be used within a few days after simple treatment with chemical reagents. Varieties of oranges and lemons which are ready for use before they have acquired a desirable colour are treated with ethylene, which quickens the respiration of the fruit and causes it to acquire the desired hue.

Modern methods of food preservation (*q.v.*) rest on bacteriology, physics and chemistry; and the transportation of food-stuffs would be impossible but for scientific contributions. In modern building construction further examples of applied chemistry can be found. Cement is produced and used under chemical control, as is the steel of our modern buildings. The multiplicity of colours, shapes and textures in building units gives mute testimony to applied chemistry and her sister sciences. The strength of materials, whether used in a skyscraper, in an automobile or a pair of shears, is due to the chemical composition and the physical state of these component elements. A great field of applied science has been in heat treatment, particularly of metals, to impart given characteristics due to a rearrangement of the crystalline structure.

Supplementing Raw Materials.—Thus far such success has met the efforts of those seeking to supplement natural raw materials that some are inclined to waste such products, confident that when necessary the chemist will provide what is needed. There is nothing to justify such a policy, though a great deal may be said of the success in finding equivalents for the products of nature. The extent to which ammonia synthesised from atmospheric nitrogen has displaced Chilean saltpetre in the world's markets is an example. Methanol (wood alcohol) synthesised from carbon monoxide and hydrogen derived from coal gas, or from carbon dioxide and hydrogen, a product in the fermentation

of corn and now made in a volume somewhat embarrassing to the distillers of hard wood, the natural source of the material, is another. Synthetic camphor has displaced the natural product for many purposes. Hard fats produced by the hydrogenation of peanut oil, cottonseed oil, and the like have become a disturbing factor as a competitor of lard. The paint and varnish industry has to adjust itself to the advent of nitro-cellulose lacquers produced by chemistry in answer to a demand for a quick-drying durable finish, particularly for metal as in automobiles, and utilizing cellulose from linters or wood pulp as a basic material. Rayon is a familiar instance and is one of the forerunners of an age of cellulose, utilized for a diversity of products, perhaps even greater than those now made from coal tar. Phenol or carbolic acid, formerly derived from coal distillation, is now produced on a large scale by synthetic means, while resins valued for their own characteristics and suitable as equivalents of naturally occurring gums, are seen on every hand.

A striking example of applied chemistry and chemical engineering is to be found in the great petroleum (*q.v.*) industry, for there would already be an embarrassing shortage of motor fuels and lubricants but for applied chemistry. To-day vast quantities of fuel are removed by activated carbons and absorptive processes from natural gas and "casinghead" gas, while the proportion of gasoline prepared by "cracking" continually mounts in comparison with that prepared by the older stripping methods of simple distillation. A forecast of what applied chemistry may do for the automobile and other places where the internal combustion motor serves is seen in work abroad, where motor fuels are now prepared commercially by the hydrogenation or liquefaction of coal and by the synthesis of a motor fuel, for which carbon monoxide and hydrogen derived from coal are the raw materials.

Applied chemistry has not neglected the household, for every room shows its presence. Under the U.S. pure food laws, chemistry guards the food-supply and with bacteriology guards the water-supply and safely disposes of the household wastes. In the house the wall and floor coverings bespeak applied chemistry, as do the colour and finish of the furniture, the dyes of tapestries and rugs, the waxes of the floors, the cleansing powders and soaps, and the brilliance of the illumination, which is due to the presence of inert gases in the incandescent bulb (*see LIGHTING*) and the ductile tungsten of the glowing filament. The glassware is made by machines under chemical control, whereas formerly it had to be hand blown. The ceramic chemist points with pride to the perfection of china. The metallurgical chemist offers evidences of his contribution not only in the metalware throughout the house, but in the kitchen, where his stainless steel owes to chromium this prized characteristic, and where stainless non-tarnishing iron or monel metal may compete with aluminium and steel in kitchen utensils. Chemistry has had a part in producing the several motors which now perform the drudgery of the household. It is a chemical compound which circulates in the mechanical refrigerator, expanding to cool the food and being compressed by the motor for expansion again. The record of the phonograph is a molded chemical compound with certain fillers, and chemistry is present throughout the radio set.

Chemistry in Warfare.—Above has been given a mere indication of chemistry applied in various directions. It is preferably a science of construction. When it tears down, it does so only for the sake of building again, using these units of construction in different ways to meet every-day requirements. When called upon, it may be destructive, for our highest explosives are made from the same raw materials which give us our medicinals of great healing power. Fortunately these explosives enter more into peace-time pursuits than into war-time activities. Being so intimately related to all industry, chemistry must go to war when called upon and has always done so. There is much evidence to support the belief that chemical warfare will be extensively used should war come again, and that it is as feasible to do without war itself as it is to eliminate chemical warfare. No war is humane, but of the various forms so far practised, statistics show chemical warfare to do less permanent damage than

other types. The World War saw used chlorine, phosgene, mustard gas, and other types of toxic and vesicant compounds. The chemistry of these and similar materials has been studied in all countries since the war, with special reference to defense measures, and it would appear that chemical warfare, while effective, nevertheless gives the intelligent man a real opportunity for self-preservation. A more extensive use of smoke screens for protective and defensive measures will doubtless be seen. These smoke screens may be nontoxic and highly efficient.

Well-meaning efforts to outlaw chemical warfare fail to take into consideration the inseparable relation between the chemicals demanded for all types of lawful peace-time industry and those needed in chemical warfare. The most effective chemical warfare agents are composed of such simple materials as sulphur, chlorine, alcohol and the like. It should also be borne in mind that the by-products of chemical research which are come upon sometimes unexpectedly may also prove to be useful materials in warfare (see **CHEMICAL WARFARE**).

The natural sciences from astronomy to zoology contribute, often in unexpected ways, to industrial development. It is improper and unbecoming for any single science to claim an undue share for what has been accomplished, but it seems fair to point out that, whatever may be contributed by the other sciences, chemistry in its application to all forms of human activity may properly be credited certainly with no less than any of her sister sciences. (See various related subjects under other headings.)

CHEMNITZ or KEMNITZ, MARTIN (1522–1586), German Lutheran theologian, was born at Treuenbrietzen, Brandenburg, on Nov. 9, 1522, and died in Brunswick on April 8, 1586. Educated at Magdeburg (1539–42) and at the universities of Frankfurt-on-Oder (1543) and Wittenberg (1545), Chemnitz became interested in mathematics and astrology, and in 1547 Melancthon gave him an introduction to Georg Sabinus at Königsberg, where he was made rector of the Kneiphof school in 1548. In 1550 Duke Albert of Prussia made him his librarian and he turned his attention to biblical studies. In a controversy with Osiander, on justification by faith, Chemnitz defended the Lutheran doctrine of imputation. In 1553 he returned to Wittenberg and gave lectures on Melancthon's *Loci Communes*, which formed the basis of his own *Loci Theologici* (published posthumously in 1591), an exposition of Lutheran theology as modified by Melancthon. Chemnitz also wrote *Repetitio sanæ doctrinæ de Vera Praesentia* (1560; in German, 1561) in support of the Lutheran view of the Eucharist, against the Crypto-Calvinists; *Theologiae Jesuitarum præcipua capita* (1562); and *Examen concilii Tridentini* (4 parts, 1565–73). In 1554 he moved to Brunswick, as coadjutor to the superintendent, Joachim Mörlin, and in conjunction with him drew up his *Corpus doctrinæ Prutenicum* (1567). In conjunction with Andrea and Selnecker he induced the Lutherans of Saxony and Swabia to unite in adopting the *Formula Concordiæ*.

BIBLIOGRAPHY.—Lives of Chemnitz are numerous, e.g., by J. Gasmerus (1588), T. Pressel (1862), C. G. H. Lentz (1866) and H. Hachfeld (1867). See also Herzog's *Realencyklopädie*, and Goschler's *Dict. encyclopédique de la théol. cath.* (1858).

CHEMNITZ, a town of Germany, in the republic of Saxony, the capital of a governmental district, 50 m. W.S.W. of Dresden and 51 S.S.E. of Leipzig. Pop. (1925) 331,655.

Chemnitz (*Kaminizi*) was originally a settlement of the Sorbian Wends and became a market town in 1143. Its municipal constitution dates from the 14th century, and it soon became the most important industrial centre in the mark of Meissen. A monopoly of bleaching was granted to the town, and thus a considerable trade in woollen and linen yarns was attracted; paper was made here, and in the 16th century the manufacture of cloth was very flourishing. In 1546 the Benedictine monastery, founded about 1136 about 2 m. north of the town, was dissolved. During the Thirty Years' War Chemnitz was plundered by all parties and its

trade was completely ruined, but at the beginning of the 18th century it had begun to recover. Further progress was made during the 19th century, especially after 1834 when Saxony joined the German *Zollverein*.

The town lies 950 ft. above sea, in a fertile plain at the foot of the Erzgebirge, watered by the river Chemnitz, an affluent of the Mulde. It is the chief manufacturing centre in the kingdom and ranks next to Dresden and Leipzig in point of population. It is well provided with railway communication, being directly connected with Berlin and with the towns of the Erzgebirge and Vogtland. The centre of the town is occupied by the market square, with the mediaeval *Rathaus*, now superseded by a modern building in the Post-strasse. The old inner town is within the old fortifications, and beyond lies industrial Chemnitz. There is an ancient Gothic church dedicated to St. James. To the north-west of the town is the Gothic church of a former Benedictine monastery, dating from 1514–1525, with a tower of 1897. The industry of Chemnitz has gained for the town the name of "Saxon Manchester." First in importance are its locomotive and engineering works. Next come its cotton-spinning, hosiery, textile and glove manufactures. It also has considerable dyeworks, bleach-works, chemical and woollen factories. The local communications are maintained by an electric tramway system. Chemnitz is a favourite tourist centre for excursions into the Erzgebirge.

CHENAB, one of the "Five rivers" of the Punjab, India (the Greek Acesines). It rises in the snowy Himalayan ranges of Kashmir, enters British territory in the Sialkot district, and flows through the plains of the Punjab, forming the boundary between the Rechna and the Jech Doabs. Finally it joins the Jhelum at Trimmu.

The Chenab colony, resulting from the success of the Lower Chenab canal in irrigating the desert of the Bar, was formed out of the three adjacent districts of Gujranwala, Jhang and Montgomery in 1892. It lies in the Rechna Doab between the Chenab and Ravi rivers in the north-east of the Jhang district, and includes an irrigated area of over 2½ million acres. The principal town is Lyallpur (pop. 1921, 28,136) called after Sir J. Broadwood Lyall, lieutenant-governor of the Punjab. It is now an important trade centre, and gives its name to a district with an area of 3,250 sq.m. and a population (1921) of 979,463. The Lower Chenab canal is now supplied with water from the Jhelum through the Upper Jhelum Canal, and the Chenab water is utilised for the upper Chenab canal. This canal, opened in 1912, which has 173 m. of main canals and distributaries, and irrigates over half a million acres, forms part of the great Triple canals project.

CHÊNE DOLLÉ, CHARLES JULIEN LIOULT DE (1769–1833), French poet, was born at Vire (Calvados). Emigrating in 1791, he fought two campaigns in the army of Condé. On his return to Paris in 1799 he met Chateaubriand and his sister Lucile (Mme. de Caud), to whom he became deeply attached. After her death in 1804, Chênédollé returned to Normandy, where he married and became eventually inspector of the academy of Caen (1812–32).

The works of Chênédollé, which include *Le Génie de l'Homme* (1807) and *Études poétiques* (1820), were edited in 1864 by Sainte-Beuve, who drew portraits of him in his *Chateaubriand et son groupe* and in an article contributed to the *Revue des deux mondes* (June 1849). See also E. Helland, *Étude biographique et littéraire sur Chênédollé* (1857); L. de Samie, *Chênédollé* (1922).

CHENERY, THOMAS (1826–1884), English scholar and editor of *The Times*, was born at Barbados and educated at Eton and Caius college, Cambridge. Having been called to the bar, he went out to Constantinople as *The Times* correspondent just before the Crimean War, and it was under the influence there of Algernon Smythe (afterwards Lord Strangford) that he first turned to those philological studies in which he became eminent. After the war he returned to London and wrote regularly for *The Times* for many years, eventually succeeding Delane as editor in 1877. He was then an experienced publicist, particularly well versed in oriental affairs, an indefatigable worker, with a rapid and comprehensive judgment, though he lacked Delane's intuition for public opinion. In 1868 he was appointed Lord Almoner's professor of Arabic at Oxford, and retained his position until he

became editor of *The Times*. He was one of the company of revisers of the Old Testament. He was secretary for some time to the Royal Asiatic Society, and edited the Arabic classic *The Assemblies of Al-Hariri* and the *Machberoth Ithiel*. He died in London on Feb. 11, 1884.

CHENG, TSCHENG or TSCHIANG (Ger. *Scheng*), an ancient Chinese wind instrument in the nature of a primitive portable organ, containing the principle of the free reed which found application in Europe in the accordion, concertina, and harmonium. In shape the cheng resembles a closed teapot to the top of which are fitted bamboo pipes of graduated lengths and furnished in the side with an insufflation tube curved like a swan's neck or the spout of a teapot.

CHÉNGTU, the administrative centre of the province of Szechwan and the regional capital of West China, situated 30° 40' N., 104° 12' E. In the north-west corner of the Red Basin of Szechwan there lies a smooth plain some 70 miles by 40, whose even surface contrasts strongly with the rest of the highly dissected Basin. Chéngtu is the centre of this plain which forms the deltaic fan of the Min-Ho below its debouchure at Kwan-hien from the high mountain country of north-west Szechwan. By means of a marvellous irrigation system, initially planned by Li Ping in the 3rd century B.C. and further elaborated at several subsequent periods, the river waters are now led off at Kwan-hien along innumerable irrigation channels to fertilize the whole plain instead of littering it with gravel as in its natural state. At the lower end of the plain the channels are drawn together and issue as two rivers, the Min-Ho, and the Chung-kiang, which join the Yangtze at Suifu and Luchow respectively. Although on the average 2,000 ft. above sea-level, the Chéngtu plain lies in a very sheltered position and yields exceptionally heavy crops of all the varied products typical of Middle China (see CHINA).

Chéngtu also serves as the commercial outlet of the mountain country of north-west Szechwan, the pastoral products of which are utilized in the industries of the city. Because of its position at the contact of plain and mountain Chéngtu focuses the life of the sheltered agricultural Red Basin and the rugged pastoral mountain country of the west Szechwan border. The Red Basin of Szechwan lies in the far west of China and Chéngtu is placed on the western border of the Red Basin. It epitomizes therefore the distinctive and isolated Szechwanese culture, and clearly constitutes the capital of interior West China. Chéngtu is the seat of the West China Union University, one of the five Union Universities of China, each of which has a definite regional significance. The region served by the West China University includes Yunnan and Kweichow as well as Szechwan. The population of Chéngtu is estimated at over 400,000.

CHÉNIER, ANDRÉ DE (1762–1794), French poet, was born at Constantinople of a French father and a Greek mother. His parents returned to France in 1765, and though the father afterwards served as consul general in Morocco, the children (Marie-Joseph is noticed below) remained in France. André was educated at the college de Navarre in Paris, and after some months in the army at Strasbourg, returned to Paris, where he met the poets and artists of the day in his mother's salon. A visit to Italy in 1784 made a deep impression on his mind, and strengthened his passion for the antique. The next three years were spent in experimenting in eclogues and idylls in the classical manner. Of the works of this period the most famous is *La jeune Tarentine*, classi-

cal in form, but characterized by the grace and charm which informed all Chénier's work. He proposed to write and actually composed fragments of a poem modelled on Lucretius, *Hermès*, which was to cover the contents of the *Encyclopédie*. In 1787 he went to London as secretary to his relative, M. de la Luzerne, at that time French ambassador. London displeased him, and in 1790 he returned to France, and plunged into political writing. His prose *Avis au peuple français* (Aug. 24, 1790) was followed by the *Jeu de Paume*, a moral ode addressed to the painter Louis David. Chénier was a member of the Feuillant club, and contributed to the *Journal de Paris* the Iambes addressed to Collot d'Herbois *Sur les Suisses révoltés*. He escaped the massacres of September because his family got him away to Normandy, and after the execution of Louis XVI. he hid in an obscure refuge near Versailles. To this period belong his *Ode à Charlotte Corday* and his *Ode à Versailles*. His lines on the art of writing poetry are still quoted in French university circles.

But on Mar. 7, 1794, he was arrested in the house of Madame Piscatory at Passy. He was lodged first in the Luxembourg and then in Saint-Lazare. His imprisonment lasted 141 days. His brother, Marie-Joseph, a member of the Convention, could not save him, and he was guillotined on July 25, 1794, three days before Robespierre, whose death would have saved him. To this four months' imprisonment belong André Chénier's greatest poems, the *Jeune Captive*, the *Iambes* (in alternate lines of 12 and 8 syllables) attacking the Convention and conveyed sheet by sheet to his friends by a venal gaoler.

These circumstances explain how it was that the greatest French lyricist of the 18th century had to wait 20 years for the merest recognition of his genius. For only fragments of his work were known, and he only reached the full measure of his powers in the months before his tragic end. Only the *Jeu de Paume* and the *Hymne sur les Suisses* were known in his life time. The *Jeune Captive* and the *La Jeune Tarentine* were published in periodicals in 1795 and 1801. The first imperfect attempt to collect the body of his work was made in 1819. Since that date there has been unanimous acknowledgment of his genius, but the critics have been divided as to whether he should be classed, as Sainte-Beuve classed him, as the forerunner of Victor Hugo and the romanticists, or, as Anatole France would have it, as the last exponent of the art of the 18th century. Perhaps his influence was greatest on the classicists who led the reaction against the romanticists at the end of the 19th century, on Leconte de Lisle and Hérédia.

BIBLIOGRAPHY.—The Chénier literature is enormous. His fate has been commemorated in numerous plays, pictures and poems, notably in the fine epilogue of Sully Prudhomme, the *Stello* of A. de Vigny, the delicate statue by Puech in the Luxembourg, and the well-known portrait in the centre of the "Last Days of the Terror." The best editions are still those of Becq de Fouquières (1862, 1872 and 1881), supplemented by those of L. Moland (2 vols. 1889) and R. Guillard (2 vols. 1899).

See also Sainte-Beuve, *Tableau de la Litt. fr.* (1828); Anatole France, *La Vie littéraire* vol. ii.; E. Faguet, *André Chénier* (1902).

CHÉNIER, MARIE-JOSEPH BLAISE DE (1764–1811), French poet, dramatist and politician, younger brother of André de Chénier, was born at Constantinople on Feb. 11, 1764. He was brought up at Carcassonne, and educated in Paris at the Collège de Navarre. After two years spent in the army he began to write plays on the Voltairian model. The notoriety attained by the later plays was due to political considerations rather than to any intrinsic literary merit. His *Charles IX.* was kept back for nearly two years by the censor; its production (Nov. 4, 1789) was an immense success, due in part to Talma's magnificent impersonation of Charles IX. Camille Desmoulins said that the piece had done more for the Revolution than the days of October, and a contemporary memoir-writer, the marquis de Ferrière, says that the audience came away "ivre de vengeance et tourmenté d'une soif de sang." The performance occasioned a split among the actors of the Comédie Française, and the new theatre in the Palais Royal, established by the dissidents, was inaugurated with *Henri VIII.* (1791), generally recognized as Chénier's masterpiece; *Jean Calas, ou l'école des juges* followed in the same year. In 1792 he produced his *Caius Gracchus*, which was proscribed in 1793 at the instance of the Montagnard deputy, Albitte, for

an anti-anarchical hemistich (*Des lois et non du sang!*); *Fénelon* (1793) was suspended after a few representations; and in 1794 his *Timoléon*, set to Étienne Méhul's music, was also proscribed. This piece was played after the fall of the Terror, but the fratricide of Timoléon became the text for unfounded insinuations that, by his silence, Joseph de Chénier had connived at the judicial murder of André. In fact Joseph knew that André's only chance of safety lay in being forgotten by the authorities, and that intervention would only hasten the end. Joseph Chénier had been a member of the Convention and of the Council of Five Hundred, and had voted for the death of Louis XVI.; he had a seat in the tribunate; he belonged to the committees of public instruction, of general security and of public safety. Nevertheless, before the end of the Terror he had become a marked man. His purely political career ended in 1802, but from 1803 to 1806 he was inspector-general of public instruction. *Cyrus* (1804) was written in honour of Napoleon, but Chénier was temporarily disgraced in 1806 for his *Épître à Voltaire*. He died on Jan. 10, 1811. The list of his works includes hymns and national songs—among others, the famous *Chant du départ*; odes, *Sur la mort de Mirabeau*, *Sur l'oligarchie de Robespierre*, etc.; tragedies which never reached the stage, *Brutus et Cassius*, *Philippe deux*, *Tibère*; a *Tableau historique* (1808) of contemporary French literature; translations from Sophocles and Lessing, from Gray and Horace, from Tacitus and Aristotle; with elegies, dithyrambs and Ossianic rhapsodies.

See *Œuvres complètes de Joseph Chénier* (8 vols., 1823–26), containing notices of the poet by Arnault and Daunou; Charles Labitte, *Études littéraires* (1846); Henri Welschinger, *Le Théâtre révolutionnaire, 1789–1799* (1881); and A. Lieby, *Étude sur le théâtre de Marie-Joseph Chénier* (1902).

CHENILLE, a twisted velvet cord, woven so that the short outer threads stand out at right angles to the central cord, thus giving a resemblance to a caterpillar. Chenille is used as a trimming for dress and furniture. The word is French and means a hairy caterpillar.

CHENONCEAUX, a village of central France, in the department of Indre-et-Loire, on the right bank of the Cher, 20 m. E. by S. of Tours on the Orléans railway. Pop. (1926) 196. Chenonceaux owes its interest to its château, a building in the Renaissance style on the river Cher. Founded in 1515 by Thomas Bohier (d. 1523), financial minister in Normandy, the château was confiscated by Francis I. in 1535. An isolated tower flanking a drawbridge is part of an earlier building of the 15th century. Henry II. presented it to Diane de Poitiers, who on his death was forced to exchange it for Chaumont-sur-Loire by Catherine de' Medici. The latter built the gallery which leads to the left bank of the Cher. Chenonceaux passed successively into the hands of Louise de Vaudémont, wife of Henry III., the house of Vendôme, and the family of Bourbon-Condé. It came into the possession of Claude Dupin (1684–1769) and in 1864 it was sold to the chemist Théophile Pélouze, whose wife executed extensive restorations.

CHENOPODIUM or GOOSE-FOOT, a genus of erect or sometimes prostrate herbs of the family Chenopodiaceae, comprising some 60 species, natives of temperate regions, some of which have cosmopolitan distribution as weeds. Of the nine species found in Great Britain practically all are naturalized in the United States and Canada. Inclusive of those introduced from the Old World, some 25 species occur in North America. A well known representative is the common goose-foot (*C. album*), called also lamb's quarters and pigweed. It is native to Europe and Asia, is found in Great Britain, and is widely prevalent in North America as a naturalized weed. The green angular stem is often striped with white or red, and, like the leaves, often more or less covered with mealy hairs. The leaves are entire, lobed or toothed and often more or less triangular in shape. The minute flowers are borne in dense axillary or terminal clusters. The fruit, usually enclosed by the persistent calyx, is a membranous utricle covering a small, black, shining seed. Among other goose-foots found in Great Britain and also naturalized in North America are the maple-leaved goose-foot (*C. hybridum*), the nettle-leaved goose-foot or sow-bare (*C. murale*), the oak-leaved goose-foot (*C. glau-*

cum), the many-seeded goose-foot (*C. polyspermum*), the city goose-foot (*C. urbicum*), and good King Henry (*C. Bonus-Henricus*). Other Old-World species naturalized in North America are the Jerusalem oak (*C. Botrys*), the Mexican tea (*C. ambrosioides*) and the wormseed (*C. anthelminticum*).

Among native North American species are the red goose-foot (*C. rubrum*), growing on saline soils on sea coasts and in the interior, and found also in Europe; the strawberry blite (*C. capitatum*), with a fleshy red fruit somewhat resembling strawberries, native to dry soil from Nova Scotia to Alaska southward to New Jersey and California, and also in Europe; and the California goose-foot or soap-plant (*C. californicum*), found in the foothills of the Sierra Nevada and Coast ranges, the grated roots of which are used as soap by the Indians.

Quinoa (*C. Quinoa*), native to the Andean region, is cultivated in South America for its seeds, used as food. The wormseed (*q.v.*) yields a drug used as a vermifuge. (See GOOD KING HENRY; JERUSALEM OAK.)

CHEOPS, in Herodotus, the name of the king who built the Great Pyramid in Egypt. Following on a period of good rule and prosperity under Rhampsinitus, Cheops closed the temples, abolished the sacrifices and made all the Egyptians labour for his monument, working in relays of 100,000 men every three months (see PYRAMID). He even sacrificed the honour of his daughter in order to obtain the money to complete his pyramid; and the princess built herself besides a small pyramid of the stones given to her by her lovers. Cheops reigned 50 years and was succeeded by his brother, Chephren, who reigned 56 years and built the second pyramid. During these two reigns the Egyptians suffered every kind of misery and the temples remained closed. Herodotus continues that in his own day the Egyptians were unwilling to name these oppressors and preferred to call the pyramids after a shepherd named Philiton, who pastured his flocks in their neighbourhood. At length Mycerinus, son of Cheops and successor of Chephren, reopened the temples and, although he built the Third Pyramid, allowed the oppressed people to return to their proper occupations.

Cheops, Chephren and Mycerinus are historical personages of the fourth Egyptian dynasty, in correct order, and they built the three pyramids attributed to them here. But they are wholly misplaced by Herodotus. Rhampsinitus, the predecessor of Cheops, appears to represent Rameses III. of the twentieth dynasty, and Mycerinus in Herodotus is but a few generations before Psammetichus, the founder of the twenty-sixth dynasty. Manetho correctly places the great Pyramid kings in Dynasty IV. In Egyptian the name of Cheops (Chemmisor Chembis in Diodorus Siculus, Suphis in Manetho) is spelt Hwfw (Khufu), but the pronunciation, in late times perhaps Khōouf, is uncertain. How far we may accept Herodotus' view of the distress caused by the building of the pyramid is doubtful. Petrie thinks that he can trace a violent religious revolution with confiscation of endowments at this time in the temple remains at Abydos; but none the less the deities were then served by priests selected from the royal family and the highest in the land. Khufu's work in the temple of Bubastis is proved by a surviving fragment, and he is figured slaying his enemy at Sinai before the god Thoth. In late times the priests of Denderah claimed Khufu as a benefactor; he was reputed to have built temples to the gods near the Great Pyramids and Sphinx (where also a pyramid of his daughter Hetsen is spoken of), and there are incidental notices of him in the medical and religious literature. The funerary cult of Khufu and Khafre was practised under the twenty-sixth dynasty, when so much that had fallen into disuse and been forgotten was revived. Khufu is a leading figure in an ancient Egyptian story (Papyrus Westcar), but it is unfortunately incomplete. He was the founder of the fourth dynasty, and was probably born in Middle Egypt near Beni Hasan, in a town afterwards known as "Khufu's Nurse," but was connected with the Memphite third dynasty. Two tablets at the mines of Wadi Maghara in the peninsula of Sinai, a granite block from Bubastis, and a beautiful ivory statuette found by Petrie in the temple at Abydos, are almost all that can be definitely assigned to Khufu outside the pyramid at Giza and its ruined

accompaniments. His date, according to Petrie, is 3969–3908 B.C., but in the shorter chronology of Meyer, Breasted and others he reigned (23 years) about a thousand years later, *c.* 2900 B.C.

See Herodotus ii. 124; Diodorus Siculus i. 64; Sethevin Pauly-Wissowa's *Realencyklopädie*, s.v.; W. M. F. Petrie, *History of Egypt*, vol. i., and *Abydos*, part ii. p. 48; J. H. Breasted, *History*.

CHEPSTOW, market town and river-port of Monmouthshire, England, on the Wye, 2m. above its junction with the Severn, and on the G.W.R. Pop. of urban district (1931) 4,303.

As the key to the passage of the Wye, Chepstow (*Estrighorel*, *Strigul*) was the site successively of British, Roman and Saxon fortifications. Domesday Book records that the Norman castle was built by William Fitz-Osbern to defend the Roman road into South Wales. The castle occupies a hill site on the western bank of the river. It was founded in the 11th and rebuilt in the 13th century. It was subsequently granted to the earls of Pembroke, and after its reversion to the crown, Edward II. granted it to Thomas de Brotherton. It passed, through Margaret, Lady Segrave, to the dukes of Norfolk, from whom, after again reverting to the Crown, it passed to the earls of Worcester. It was confiscated by parliament but restored to the earls in 1660. The church of St. Mary, originally the conventual chapel of a Benedictine priory, has some old features. The borough must have grown up between 1310, when the castle and vill were granted to Thomas de Brotherton, and 1432, when John duke of Norfolk died seised of the castle, manor and borough of Striguil. In 1524 the earl of Worcester granted a new charter to the bailiffs and burgesses of the town, which had fallen into decay. This was sustained until the reign of Charles II., when, some dispute arising, the charter lapsed and the town was afterwards governed by a board of twelve. A port since early times, when the lord took dues of ships going up to the forest of Dean, Chepstow had no ancient market and no manufactures but that of glass, which was carried on for a short time within the ruins of the castle. A local trade during the 19th century was handicapped by the narrowness and depth of the channel and the consequent tidal bore. There is a race-course 1½m. N.W. of the town.

CHEQUE or CHECK. A cheque, in the simple definition of the English law, "is a bill of exchange drawn on a banker payable on demand." It has proved in practice to be a credit instrument of astonishing usefulness. No one could have foreseen that the cheque would become the chief currency of domestic commerce in Great Britain and the United States. What is perhaps equally surprising is that the British and American example has not been more largely followed in other countries. Over 90 per cent of the internal financial and wholesale trading transactions of Great Britain and the United States are settled by cheque. On the continent of Europe the cheque system is comparatively undeveloped, but it is everywhere making headway, especially in France and Germany. That the cheque will eventually come into universal use cannot be doubted.

The word "cheque," of which "check" is a variant, originally signified the counterfoil or indent of an exchequer bill, or any draft form of payment, on which was registered the details of the principal part, as a "check" to alteration or forgery. The check or counterfoil parts remained in the hands of the banker, the portion given to the customer being termed a "drawn note" or "draft." From the beginning of the nineteenth century the word "cheque" gradually became synonymous with "draft" as meaning a written order on a banker by a person having money in the banker's hands, to pay some amount to bearer or to a person named. Ultimately, the word "cheque" entirely superseded the word "draft."

The law relating to cheques, which is generally one with that of bills of exchange, but has some different and supplemental points, is dealt with elsewhere (*see* **BILLS OF EXCHANGE**). Here we note some of the chief precautions which should be used in drawing cheques.

Cheque Forms.—London banks use a form printed "or order"; the payees cannot obtain the money without "endorsing" the cheque. Therefore no other person could obtain the money without committing forgery. Further, the form may be printed "crossed";

two lines being printed across it. A cheque so crossed can only be cashed through a banker, so that, if we imagine the endorsement to be forged, the forger could not cash the cheque without the aid of a person with a banking account to put the cheque through for him. Further, the drawers of the cheque often take the precaution of adding the words "a/c Payees only" to the crossing. That means that no person other than the payees could obtain payment, even though a forger had signed the payee's name on the back.

In drawing cheque for eight pounds, for example, the words should be carefully written close to the printed words "the sum of," and also close to each other, to prevent the insertion of forged figures, while the space not needed for words is filled in with a thick wavy line. The "t" of "eight" and the "p" of pounds, are written closely together to prevent the insertion of a "y" to turn "eight" into "eighty." For the same reason, the figures are carefully written and the spaces between them filled with lines. As a further precaution, the words "under nine pounds" are written in the top left hand corner. A cheque thus drawn with care and intelligence can hardly be misused, but business firms often take the further precaution of using a machine which perforates the figures as it prints them. A cheque may legally be drawn upon a plain piece of paper, but this, fortunately for the bankers, is rarely done; it is only too likely to lead to mistake and loss. The adoption of an inimitable form of signature by those who draw many cheques should be carefully considered. It is a curious fact that wholly or partly illegible signatures are much safer than those carefully or very legibly written, for a well or beautifully written name is easily imitated by the forger.

Bankers issue to their customers on request cheque-forms either to "bearer" or to "order," and printed either crossed or left uncrossed. It is far the best way to use cheque forms printed "or order" and crossed. If it is desired to make the cheque payable to "bearer" this can be done by crossing out the word order and signing the alteration. Again, if it is desired to cancel the printed cross lines this can be done by writing across them "Pay cash" and signing the alteration.

The usual form of an American cheque carries at the top the date of issuance, the name of the bank on which it is drawn and a number for convenient identification. This is followed by the printed words "Pay to the order of" and a space in which is written the name of the payee. On the next line the amount in dollars is written out and the cents usually shown in figures. There is also provided a place for writing the whole amount of the cheque in figures. At the bottom appears the signature of the maker. To collect the cheque the payee must endorse it exactly as his name is written. When so endorsed the cheque is good in the hands of anyone, as is the case with a cheque made payable to cash. The signature of the person cashing it is usually required. The precautions stated above should be used in drawing the cheque.

The Cheque as Receipt.—The cheque form has come into common sense use as a means of giving a receipt conveniently and expeditiously. It is not surprising that it occurred to business men that as a cheque has to be endorsed on the back by the payee, it would make short work of detail by turning that endorsement into a definite receipt for the money paid. Accordingly, in an increasing number of cases, business firms print on the back of the cheques they use a form of a receipt for the payee to sign. As cheques are always sent back to the drawers when cleared by their bankers, the drawers have only to paste the returned cheques in their cheque book to have a complete and combined record of payments and receipts. A further development of the cheque form has naturally followed. The custom of endorsing a cheque on the back is a strange one. To find such an endorsement one has to turn the cheque over, and it is never well in matters of record to write or print on both sides of the paper. The endorsement on the back of a cheque, useful as it is, is thus seen as a combination of usefulness and inconvenience. Realising this, some business houses have boldly brought the endorsement on to the front of the cheque and at the same time made it a receipt form. This somewhat enlarges the size of the cheque form, but

the complete record can be contrived within a space of 7 or 8 in. by 5 or 6 in. It is probable that so simple and convenient a method of combining payment, endorsement and receipt will come into wide use (*see* BILL OF EXCHANGE; BANKING AND CREDIT; MONEY MARKET: BANK).

CHEQUERS. Chequers Court, near Princes Risborough, Buckinghamshire, became an official residence of British prime ministers in 1921 through the generosity of its owners, Lord and Lady Lee of Fareham. The estate is about 1,500 ac. in extent.

Here Caractacus had a stronghold, of which the earthworks are still visible. "Radulphus," clerk to the Exchequer, was owner under Henry II., and the place appears to have taken its name from his office. In 1565, his descendant, William Hawtreay, remodelled the house and gave it much of its present character and appearance. In the 18th century, a unique collection (which still remains) of Cromwell portraits and other relics was brought by the Russells, who were descended from one of the Protector's daughters. The Russells maintained the Elizabethan house with little alteration, but Robert Greenhill, who inherited from them early in the 19th century, plastered the whole of the outside and redecorated the interior in Strawberry Hill Gothic fashion.

When the Lees entered on a long tenancy in 1909 they sought to reveal all the remaining ancient features, and to introduce others characteristic of the days of the Hawtreys and the Russells. In 1917 Lord and Lady Lee changed their tenancy into a freehold, and created a trust, which, on their deaths should make the house an adequate seat where the prime ministers could entertain guests. The original draft for the Chequers Trust declared that:—"The main features of the scheme are, therefore, designed not merely to make Chequers available as the official country residence of the prime minister of the day, but to tempt him to visit it regularly, and to make it possible for him to live there, even if his income should be limited to his salary. With this object a sufficient endowment is provided to cover the cost of a permanent nucleus staff of servants, of keeping up the gardens and grounds, of maintenance and repairs, and other necessary outgoings. There is also a residential allowance for the official occupant calculated in a fashion deliberately designed to encourage regular week-end visits." The draft, however, insisted upon the unaltered preservation of both house and contents.

In 1920 Lord and Lady Lee resolved that this generous scheme should not await their death but should take immediate effect. All the preparations for establishing and working the trust having been completed, the prime minister held his house-warming on Jan. 8, 1921. His successors have spent part of their time here during their terms of office and ministerial week ends at Chequers Court have become a part of English political life.

CHER, a department of central France, embracing the eastern part of the ancient province of Berry, and parts of Bourbonnais, Nivernais and Orléanais, bounded north by the department of Loiret, west by Loir-et-Cher and Indre, south by Allier and Creuse, and east by Nièvre. Pop. (1926) 298,398. Area 2,819 square m. Oolitic rocks occupy much of the department but are covered by Cretaceous and Tertiary deposits in the north. The higher well-drained land of the south and east is suitable both for cultivation and for pasturage. The valley of the Loire is especially fertile and the eastern, sunny slopes are noted for their vines, particularly in the neighbourhood of Sancerre. Wheat and oats are largely cultivated, whilst hemp, vegetables and fruits are also produced. The central districts are fertile but are low-lying and marshy, being often flooded by the Cher. The department contains much pasturage whence considerable trade in horses, cattle, sheep and wool for the northern markets. Many parts, also, are well-wooded. The chief rivers, besides the Cher and its tributaries, are the Grande Sauldre and the Petite Sauldre on the north, but the Loire, which forms the eastern boundary, and the Allier, though not falling within the department, drain the eastern districts, and are navigable. The Cher itself becomes navigable when it receives the Arnon and Yèvre, and communication is greatly facilitated by the Canal du Berry, the lateral canal of the Loire, which follows the left bank of that river, and the canal of the Sauldre. Mines of iron are worked and stone is quarried. There are brick, porcelain

and glassworks, flour-mills, distilleries, oil-works, saw-mills and tanneries. Bourges and Vierzon are metallurgical and engineering centres. The department is served by the Orléans railway. It is divided into the two arrondissements (29 cantons, 2,913 communes) of Bourges and Saint-Amand-Mont-Rond, of which the former is the capital and the seat of an archbishop and of a court of appeal. The department belongs to the *académie* (educational division) of Paris, Bourges, Saint-Amand-Mont-Rond, Vierzon and Sancerre (*q.v.*) are the principal towns. Méhun-sur-Yèvre (pop. 4,551), a town with porcelain manufactures, has a Romanesque church and a château of the 14th century. The church at St. Satur has a fine choir of the 14th and 15th centuries; those of Dun-sur-Auron, Plaimpied, Aix d'Angillon and Jeanvrin are Romanesque in style, while that at Aubigny-Ville is of the 12th, 13th and 15th centuries. Drevant, on the site of a Roman town, preserves ruins of a theatre. The Pierre-de-la-Roche, at Villeneuve-sur-Cher, is the most notable megalithic monument.

CHERAT, a hill cantonment and sanatorium in the Peshawar district of the North-West Frontier province, India, 34 m. S.E. of Peshawar. It is situated at an elevation of 4,500 feet. It was first used in 1861, and since then has been employed during the hot weather as a health station for the British troops quartered in the vale of Peshawar.

CHERBOURG, a naval station, fortified town and seaport of north-western France, capital of an arrondissement in the department of Manche, on the English Channel, 232 m. W.N.W. of Paris on the Ouest-État railway. Pop. (1926) 32,030. Cherbourg is situated at the mouth of the Divette, on a small bay at the apex of the indentation formed by the northern shore of the Cotentin peninsula, backed by the steep Montagne du Roule.

History.—Cherbourg is supposed to occupy the site of the Roman station of *Coriallum*, but nothing definite is known about its origin. The peninsula, stretching far towards the Isle of Wight, seems to have been used by prehistoric traders of the bronze age as a starting place for the British Isles. William the Conqueror, under whom the settlement appears as *Carusbur*, provided it with a hospital and a church; and Henry II. of England on several occasions chose it as his residence. Under Philip Augustus it became of military importance; in 1295 it was pillaged by an English fleet from Yarmouth, and in the 14th century it frequently suffered during the wars against the English. Captured by the English in 1418 after a four months' siege, it was recovered by Charles VII. of France in 1450. An attempt was made under Louis XIV. to construct a military port. Fortifications constructed by Vauban in 1686 were dismantled in 1689. Harbour-works were begun under Louis XVI. and continued by Napoleon I. It was left, however, to Louis Philippe, and Napoleon III., to complete them. By 1858, £8,000,000 had been expended on the works; in 1889 the harbour was farther extended.

Harbours.—The naval and commercial harbours are distant from each other about half a mile. The former consists of three main basins cut out of the rock, and has an area of 55 acres. The minimum depth of water is 30 ft. Connected with the harbour are dry docks, ship-building yards, magazines, rope walks, etc. There is a large naval hospital close to the harbour. The commercial harbour at the mouth of the Divette communicates with the sea by a channel 650 yd. long. It consists of two parts, an outer and tidal harbour 17½ acres in extent, and an inner basin 15 acres in extent, with a depth on sill at ordinary spring tide of 25 ft. Outside these harbours is the triangular bay, which forms the roadstead of Cherbourg. The bay is naturally sheltered on every side but the north, where lies the huge breakwater 2½ m. in length (begun by Louis XVI.), with a width of 650 ft. at its base and 30 ft. at its summit, which is protected by forts, and leaves passages for vessels to the east and west. The trans-atlantic liners lie to within this *digue*.

Near the roadstead is the church of La Trinité, a good example of the Flamboyant style (1423-1504), and one of the few historic buildings of Cherbourg. A rich collection of paintings is housed in the *hôtel de ville*. A statue of the painter J. F. Millet, born near Cherbourg, stands in the public garden. Cherbourg is a fortified place of the first class, headquarters of one of the five

naval arrondissements of France, and the seat of a sub-prefect. It has tribunals of first instance and of commerce, a chamber of commerce, and a naval school. The chief industries of the town proper are fishing, saw-milling, tanning, ship-building, iron- and copper-founding and rope-making. The bathing beach is frequented by local holiday-makers. Cherbourg is a port of call for trans-atlantic steamers. The chief exports are stone for road-making, butter, eggs and vegetables; the chief imports are coal, timber, superphosphates and wine from Algeria. Great Britain is the principal customer.

CHERBULIEZ, CHARLES VICTOR (1829-1899), French novelist and miscellaneous writer, was born at Geneva, where his father, André Cherbuliez (1795-1874), was a classical professor at the university. He resumed French citizenship and was elected a member of the Academy (1881). Cherbuliez wrote many novels, showing the influence of George Sand, of which the following are the best known: *Le Comte Kostia* (1863), *Le Prince Vitale* (1864), *Le Roman d'une honnête femme* (1866), *L'Aventure de Ladislas Bolski* (1869), *La Vocation du Comte Ghislain* (1888), *Le Secret du précepteur* (1893), *Jacquine Vanesse* (1898). He also contributed literary and historical studies to the *Revue des deux Mondes* and *Le Temps*, many of which were collected in book form in *L'Allemagne politique* (1870), *Études de littérature et d'art* (1873), *Profilis étrangers* (1889), etc. See E. Ritter, *Victor Cherbuliez* (1900).

CHERCHEL, a seaport of Algeria, in the arrondissement and department of Algiers, 55 m. W. of the capital. Pop. 7,486. It is the centre of an agricultural and vine-growing district, but is commercially of no great importance. The town is chiefly noteworthy for the extensive ruins of former cities on the same site.

Cherchel was a city of the Carthaginians, who named it Jol. Juba II. (25 B.C.) made it the capital of the Mauretanian kingdom under the name of Caesarea. Destroyed by the Vandals, Caesarea regained some of its importance under the Byzantines. Taken by the Arabs it was renamed by them Cherchel. Khair-ed-Din Barbarossa captured the city in 1520 and annexed it to his Algerian pashalik. In 1840 the town was occupied by the French. The ruins suffered greatly from vandalism during the early period of French rule, many portable objects being removed to museums in Paris or Algiers, and most of the monuments destroyed for the sake of their stone. The museum contains some of the finest statues discovered in Africa.

See V. F. Godell, *Les monuments antiques de l'Algérie* (1901).

CHEREPOVETZ, a town and province in the Leningrad area (g.v.) of the Russian Socialist Federal Soviet Republic. The area of the province is 47,623 sq. km., and the population (1926) 607,735, mainly rural. The soil is mainly of the podzolized bog type favourable to tree growth (see RUSSIA, *Soils*) and 76% of the province is forested. The climate is dry and cold, and the waterways are frozen six months in the year; of the average rainfall of 20 to 25 in., most falls in July and August. The summer temperature averages 65° F. Much timber is exported in a raw state to Leningrad and Moscow or to foreign countries: there is little manufacture of furniture or other wooden goods. The timber is floated down the waterways on rafts when the spring thaws begin. During the World War and the Intervention (1914-21), saw-milling and timber works fell off, partly through the blockade of foreign markets and partly through the cessation of building operations. By 1924 it had reached only 50% of the 1913 level. Koustar (peasant) industries in charcoal burning and the production of pitch and tar are carried on in all the forest areas. Hunting is a profitable occupation, mainly for export. Squirrel, fox, marten and pole-cat fur have the widest sale; other animals hunted are otter and marsh otter, white hare, ermine, lynx, wolf and brown bear. During the war and civil war 1914-21, hunting practically ceased, and wolves and bears became so numerous that they attacked the villagers, and it has been necessary to offer rewards for their heads. In 1925 the export of furs from the area reached two-thirds of the pre-war level. In the sown area, the chief crops are rye, oats, barley, wheat and buckwheat, which together form 83.5% of the crops. Potatoes, flax and hay are also produced. In the famine year 1921-22, Cherepovetz had a

good harvest, since it is largely under the influence of the western cyclonic system and was unaffected by the eastern drought conditions. Cattle, horses, sheep and pigs are reared and a co-operative system of dairy artels is developed for the supply of Moscow and Leningrad. Of industries other than timber working, only the production of matches and leather goods reached pre-war level. Printing, the making of small metal goods and work on electric stations are slightly developed, the respective percentages being 1.6, 2.1 and .9. Roads are poor and in many areas do not exist at all, the only railway is the east to west line which links Leningrad with Vologda, and freightage is mainly by the waterways, especially that linking with the famous Marii network to Leningrad.

The town of Cherepovetz, lat. 59° 8' N., long. 37° 55' E., pop. (1926) 18,640, is the administrative centre. It is situated at the junction of the Yagorba and Sheksna rivers, which drain into the Volga, and during the spring thaws the banks of these streams are submerged. The Voskresensk monastery, of ancient foundation, certainly prior to the 15th century, led to a settlement of peasants near it, and this settlement was raised to town rank in 1780 and given the name of Cherepovetz. Its situation on the railway and waterways makes it a centre for the products of the province. Agricultural implements and boots and shoes are made in the town, and there are a brandy distillery and a timber mill.

CHERIBON (Tjerebon), a residency of the island of Java, Dutch East Indies, bounded south by East Preanger and Banyumas residencies, north-west and west by Indramayu residency, north by the Java Sea, and east by the residency of Pekalongan: it is included in the government of West Java. Pop. (1926) 1,005,913, including 1,895 Europeans and Eurasians, and 21,138 foreign Asiatics, Chinese included. Although some Javanese live in the north, Cheribon is Sundanese country, its eastern boundary divides the Sundanese from the Javanese territory of Central Java. Cheribon has been for many centuries the centre of Mohammedanism in West Java, for it is here that the Mohammedan power was strongly established as early as 1526, under Gunung Jati and much of the opposition to Dutch rule at a later date came from this district. The native population is now, on the whole, orderly and prosperous. The northern half of the residency is flat and marshy in places, while the southern half is mountainous. In the south stands the huge volcano Cherimaj, clad with virgin forest and plantations, and surrounded at its foot by rice fields. Sulphur and salt springs occur on the slopes of Cherimaj, and near Palimanan there is a cavernous hole called Guwagalang (or Payagalang), which exhales carbonic acid gas, and which is considered holy by the natives, and is guarded by priests. The principal products of cultivation are tea, rice, essential oils, sugar, cinchona, cassava and ground nuts and pulses, the tea and other plantations for the most part being owned by Europeans. The chief towns are Cheribon (pop. 33,051 with 971 Europeans and Eurasians and 5,451 Chinese), a seaport and the capital, Palimanan, Chiledug and Kuningan. Cheribon has a good open roadstead, and quay and warehouse-accommodation for the lighters into which cargo is discharged. The town is very old and irregularly built, and its climate is not healthy; nevertheless it has a large export trade in sugar, and is a regular port of call. Cheribon was the residence of the powerful sultans of Tjerebon, and their descendants live there still, on pension, the head of the house being styled the Sultan Sepoeh. Kuningan, famous for a breed of horses, is a hill resort (2,200 ft.) much resorted to by Europeans. Imports and exports respectively, in 1927, were, for Cheribon, 42,135,609 and 22,178,534 guilders.

CHERIMOYA or **CHERIMOYER** (*Anona Cherimola*), a sub-tropical fruit of the custard-apple family (Anonaceae), sometimes called Peruvian custard-apple. It is probably native to the mountains of Ecuador and Peru whence several centuries ago it spread by cultivation to Mexico, Central America and the West Indies; later to the Hawaiian islands, Mediterranean countries, Africa, India and Polynesia, and recently to the southern United States. It succeeds best in a comparatively cool and dry summer climate, and in the tropics must be grown at considerable elevation. It does well in protected foot-hill regions of California and also in southern Florida where there is little frost. The fruits

are roundish to oblong conical, greyish-brown or nearly black, three to five pounds or more in weight, with the skin either smooth or with warty tubercles on the surface. The flesh is soft, sweet, rich and deliciously flavoured. Propagating is done by shield budding or cleft grafting on seedling stocks two years old, and stocks of other species of *Anona* are sometimes used. Mature trees are from 15 to 20 ft. high.

CHERKASY, a town in the Shevchen (Cherkassk) area of the Ukrainian S.S.R., 49° 25' N., 32° 3' E. Pop. (1926) 38,563. It is situated near the right bank of the Dnieper, at the south-eastern termination of a patch of forest. It has a radio-station and is on the north to south railway which links Chernigov with Odessa. The inhabitants (Little Russians) are employed in agriculture and gardening. Sugar and tobacco are manufactured, and there are timber mills and veneering works and factories for nail and brick making. Cherkasy was an important town of the Ukraine in the 15th century, and remained so, under Polish rule, until the revolt of the Cossack *hetman*, Chmielnicki (1648). It was annexed by Russia in 1795.

CHERNIGOV, a town and county in the Ukrainian S.S.R. The county has an area of 10,685 sq.km., and is much smaller than the former Chernigov government. The Dnieper river forms its western boundary; its eastern boundary reaches long. 32° E. in the north, but towards the south is further west and runs parallel with the left bank of the Desna river. Its northern boundary coincides with that of the Ukraine, and the county of Kiev lies to the south. The north-west between the Dnieper and the Desna is forested, with marshes near the rivers, but the area on the left bank of the Desna lies in the transitional forest-steppe zone. In the north-west lumbering and the production of wooden wares, tar, pitch and leather goods are the main peasant occupations, beekeeping forming a useful supplement. The sown area is small, the marshy and sandy soil being unfavourable to agriculture. The chief crops are rye and oats. Hemp is also cultivated. The Desna river and its tributaries are navigable in summer and form outlets for timber. The climate is severe, the rivers being frozen for about 130 days. The town of Chernigov lat. 51° 31' N., long. 31° 20' E. has an average Jan. temperature of 23° F and July 68.5° F. The population increased from 27,716 in 1897 to 34,359 in 1926; the chief occupations are the making of spirits, leather goods, especially footwear and flour-milling. The town is a river port, with an elevator and a radio-station; it is the terminus of a branch railway. It has had a long and eventful history and was mentioned in the treaty of Oleg, 907, as next in importance to Kiev. In the 11th century it became the capital of the principality of Syever'sk, and its cathedral dates from that time. The Mongol invasion 1239 destroyed its prosperity. In the 14th century it was annexed by Lithuania, but the Poles captured and retained it until its occupation by the Russians in 1686.

CHERNYSHEVSKY, NIKOLAY GAVRILOVICH (1823-1889), Russian writer and political leader, was born at Saratov. His first works dealt with literary criticism (*The Aesthetic Relations of Art to Reality*, 1855, and *Studies of the Age of Gogol*). In the great reform movement which set in after the Crimean War, Chernyshevsky took a most active part. His journal, *The Contemporary*, urged a programme of education, more railways and a "rational distribution of economic forces"—in other words, the emancipation of the serfs. On this last point he laid particular stress, and when the tsar Alexander put forward his first reform programme (Jan. 1858), Chernyshevsky in *The Contemporary* ranked him higher than Peter the Great. The incompleteness of the agrarian reform, when promulgated, and the delays in its execution, ended, however, in turning Chernyshevsky against the Government, and he, with his colleague Dobrolyubov, became the leaders of the radical party which demanded immediate and wholesale reform. A visit to Hertzén in London convinced Chernyshevsky of the futility of the Liberal movement, and resulted in a definite rupture between the Liberals and Radicals. Chernyshevsky, now supported by the Nihilists, increased his agitation till his sudden arrest in 1862. He was tried in 1864 and sent for 24 years to Siberia. During his imprisonment in the fortress

of St. Petersburg he had written his famous novel *Shto Delat* ("What is to be done?", 1863, Eng. trans. under the title *The Vital Question*, 1866)—a classic of the revolutionary movement which earned him his severe sentence. In 1883 he was transferred from north Siberia to Astrakhan, where he began to translate Weber's *Universal History*. In 1889 he was allowed to return to Saratov, where he died, broken in health, a few months after.

See G. Plekhanov, *N. G. Tschernyshevsky* (Stuttgart, 1894).

CHEROKEE (chër'o-ke). This tribe, of Iroquoian lineage, is one of the largest in the United States. They inhabited the southern Alleghenies, where the Carolinas, Georgia, Alabama, and Tennessee adjoin. Their name seems to be of Muskogi origin and to mean "cave people." Encountered by De Soto in 1540, they first came into contact with the British in the latter half of the 17th century. They fought on the British side in the American Revolution, refusing to make peace until ten years after its termination. White settlement pressing in upon them, part of the tribe withdrew beyond the Mississippi, but the remainder, in 1820, formed a government modelled on that of the United States and soon after adopted the alphabet, or rather syllabary, invented by one of their half-bloods, Sequoyah. In 1838 the nation was reunited in Indian Territory, now Oklahoma, where they were recognized as one of the "five civilized tribes" and set up their capital at Tahlequah, their government remaining effective until 1906, when all Cherokees became United States citizens. Their original numbers were about 15,000, making them one of the largest tribes in North America. Admixture of white and negro blood, and adoption of aliens of all three races, as well as vigour of the Cherokee stock, have doubled this number.

The Cherokee were divided into seven matrilineal clans. Their general culture was similar to that of the tribes of Muskogi (*q.v.*) stock to the south. See Royce, *Bur. Am. Ethn. Rep. V.* (1887); Mooney, *ibid.* xix. (1902).

CHEROKEE, a city of north-western Iowa, U.S.A., on the west bank of the Little Sioux river, 60m. E.N.E. of Sioux city; the county seat of Cherokee county. It is a division point on the Illinois Central railroad. The population in 1930 was 6,443. Cherokee is the trade centre for a rich farming, dairying, and stock-raising country. A State hospital for the insane, accommodating 1,250 patients, is located here.

The first log house in the county was built in 1866, 4m. S. of the city, by Robert Perry, who soon thereafter met a colony of emigrants from Milford (Mass.), and persuaded them to settle near by. Two black walnut logs from their first stockade are preserved as a historic relic; and the mill-stones from the first mill have been set up as a monument. When the railway reached the county (1871) the present town-site was located, about a mile from the old town. Just south of the city is Pilot Rock, a huge glacial boulder, 40 x 60ft., which was a well-known landmark in the days of migration westward.

CHEROOT, a cigar made from tobacco grown in Southern India and the Philippine islands. The quality of cheroots varies a great deal, but a good example is esteemed for its delicate flavour. A cheroot differs from other cigars in having both ends cut square, instead of one being pointed, and one end considerably larger than the other. Cheroot, which is also sometimes spelled sheroot, is from the Tamil *shurutu*, meaning a roll.

CHERRAPUNJI, a village in the Khasi Hills district of Assam. It is notable as having the heaviest known rainfall in the world. Its annual average is 429in., but the fall varies greatly; 905in. were registered in 1861 (366in. falling in July), and only 283in. in 1873. This excessive rainfall is caused by the fact that Cherrapunji stands on the edge of the plateau overlooking the plains, where it catches the full force of the monsoon from the Bay of Bengal.

CHERRY. As a cultivated fruit-tree the cherry is generally supposed to be of Asiatic origin, whence, according to Pliny, it was brought to Italy by Lucullus after his defeat of Mithridates, king of Pontus, 68 B.C. As with most plants which have been long and extensively cultivated, it is a matter of difficulty, if not an impossibility, to identify the parent stock of the numerous cultivated varieties of cherry; but they are generally referred to

two species: *Prunus Cerasus*, the wild or dwarf cherry, the origin of morello, duke and Kentish cherries, and *P. Avium*, the gean, the origin of the geans, hearts, mazzards and bigarraeus. Both species grow wild through Europe and western Asia to the Himalayas, but the dwarf cherry has the more restricted range of the two in Britain, as it does not occur in Scotland and is rare in Ireland. The cherries form a section *Cerasus* of the genus *Prunus*;

FROM "MEDIZINAL PFLANZEN," BY PERMISSION OF FR. EUGEN KOEHLER
THE SOUR OR DWARF CHERRY (*PRUNUS CERASUS*), A TREE CULTIVATED FOR ITS FRUIT SINCE ANCIENT TIMES. PROBABLY INTRODUCED INTO EUROPE FROM ASIA ABOUT THE BEGINNING OF THE CHRISTIAN ERA

and they have sometimes been separated as a distinct genus from the plums proper; both have a stone-fruit or drupe, but the drupe of the cherry differs from that of the plum in not having a waxy bloom; further, the leaves of the plum are rolled (*convolute*) in the bud, while those of the cherry are folded (*conduplicate*).

The cherries are trees of moderate size and shrubs, having smooth, serrate leaves and white flowers. They are natives of the temperate regions of both hemispheres; and the cultivated varieties ripen their fruit in Norway as far as 63° N. The geans are generally distinguished from the common cherry by the greater size of the trees, and the deeper colour and comparative insipidity of the flesh in the ripe fruit, which adheres firmly to the "nut" or stone; but among the very numerous cultivated varieties specific distinctions shade away so that the fruit cannot be ranged under these two heads. The leading varieties are recognized as bigarraeus, dukes, morellos and geans. Several varieties are cultivated as ornamental trees and on account of their flowers.

In North America both species of cultivated cherries are widely grown. The varieties of *Prunus cerasus* are grouped as sour cherries; those of *P. avium* as sweet cherries. The sour cherry in North America is very cosmopolitan and is grown from Newfoundland to Vancouver island, on the North and to Texas and Florida on the south, yielding fruit in a score or more varieties in a greater diversity of soils and climates than any other tree fruit. On the other hand, the sweet cherry in the New World is fastidious as to soils, lacking in hardiness to both heat and cold, and is prey to many insects and fungous diseases; therefore it is grown at its best in comparatively few and limited areas. Taken together, varieties of sweet and sour cherries are the most commonly cultivated of all tree fruits in North America.

The cherry is a well-flavoured sub-acid fruit, and is much esteemed for dessert. Some of the varieties are particularly selected for pies, tarts, etc., and others for the preparation of preserves, and for making cherry brandy. The fruit is also very extensively employed in the preparation of the liqueurs known as kirsch-

wasser, ratafia and maraschino. Kirschwasser is made chiefly on the upper Rhine from the wild black gean, and in the manufacture the entire fruit-flesh and kernels are pulped up and allowed to ferment. By distillation of the fermented pulp the liqueur is obtained in a pure, colourless condition. Ratafia is similarly manufactured, also by preference from a gean. Maraschino, a highly valued liqueur, the best of which is produced at Zara in Dalmatia, differs from these in being distilled from a cherry called marasca, the pulp of which is mixed with honey, honey or sugar being added to the distillate for sweetening. It is also said that the flavour is heightened by the use of the leaves of the perfumed cherry, *Prunus Mahaleb*, a native of central and southern Europe.

The wood of the cherry tree is valued by cabinetmakers, and that of the gean tree is largely used in the manufacture of tobacco pipes. The American wild cherry, *Prunus serotina*, is much sought after, its wood being compact, fine-grained, not liable to warp, and capable of receiving a brilliant polish. The kernels of the perfumed cherry, *P. Mahaleb*, are used in confectionery and for scent. A gum exudes from the stem of cherry trees similar in its properties to gum arabic.

CHERRYVALE, a city of Montgomery county, in south-eastern Kansas, U.S.A., served by the Frisco, the Santa Fe and the Union Traction (electric) railways. The population in 1930 Federal census was 4,251. It is surrounded by rich farmland, lying over deposits of gas and oil. Its industries include a zinc smelter, a large flour-mill, an oil refinery and two large brick plants. The city was laid out in 1871 by a railway company later absorbed in the Santa Fe system. Natural gas was discovered in 1889, and oil a few years later.

CHERRY VALLEY, a village of Otsego county, New York, U.S.A., in a township of the same name, 68 m. N.W. of Albany. Pop. (1920) 728; (1930) 707, of the township (1920) 1,400; (1930) 1,326. It is served by the Delaware & Hudson railway. Cherry Valley is in the centre of a rich farming and dairying region, has a chair factory, and is a summer resort with sulphur and lithia springs. It was the scene of a terrible massacre during the War of Independence. The village was attacked on Nov. 11, 1778, by Walter Butler (d. 1781) and Joseph Brant with a force of 800 Indians and Tories, who killed about 50 men, women and children, sacked and burned most of the houses, and carried off more than 70 prisoners, who were subjected to the greatest cruelties, many dying or being tomahawked before the Canadian settlements were reached. Cherry Valley was incorporated in 1812.

CHERSIPHON, a Cretan architect, the traditional builder (with his son Metagenes) of the great Ionic temple of Artemis at Ephesus in the 6th century B.C. Remains of this temple were found by J. T. Wood and brought to the British Museum. A fragmentary inscription supports the statement of Herodotus that the pillars were presented by King Croesus.

CHERSO, one of the three major islands of the Quarnero group, which lies off the east coast of the peninsula of Istria. With the adjacent island of Lussin it was transferred to Italy in the settlement after the World War and is included in Venezia Giulia, while Veglia, the third member of the group, is attached to Yugoslavia. Cherso, 35m. long and 8m. wide has a total area of 154 square miles. It is separated from Lussin by a navigable channel, crossed by a swing bridge, the channel being believed to be artificial and the result of Roman work. The Roman town of Ossero, now a village but formerly the capital of Cherso, stands where the two islands approach most closely. Lussin, though having an area of only 28 sq.m., has a larger population than Cherso and contains in Lussin Piccolo a harbour of some importance, while Cherso harbour has no great value. Both islands are structurally a part of the karst plateau of Istria, and show similar features, with numerous swallow-holes and patches of fertile red earth. Cherso contains the interesting karstic L. Vrana. Wine, olive oil and fruits are produced in both, but Cherso, which is mountainous, rising to over 2,000ft., is devoted largely to sheep-rearing. Under the Austrians the population of Cherso, about 8,000, was registered as predominantly Serbo-Croat, the Italians forming a minority. But Cherso and Lussin formed together one district, and Italians so largely predominated in the latter island as to make the

total figures for the two stocks practically equal. Since the Italians regarded the Austrian figures as favouring the Serbo-Croat element at their expense the frontier was drawn to include both islands within Italy.

See "The Austrian Littoral," Foreign Office *Peace Handbook*, 10.

CHERSONESE, CHERSONESUS or CHERRONESUS, a word equivalent to "peninsula" (Gr. *χέρσος*, dry, and *νῆσος*, island). In ancient geography the Chersonesus Thracica, Chersonesus Taurica or Scythica, and Chersonesus Cimbrica correspond to the peninsulas of the Dardanelles, the Crimea and Jutland; and the Golden Chersonese is usually identified with the peninsula of Malacca. The Tauric Chersonese was further distinguished as the Great, in contrast to the Heracleotic or Little Chersonese at its south-west corner, where Sevastopol now stands.

History.—The *Tauric Chersonese* (from the 2nd century A.D. called Cherson) was a Dorian colony of Heraclea in Bithynia, founded in the 5th century B.C. in the Crimea about 2 m. S. of the modern Sevastopol. After defending itself against the kingdom of Bosphorus (*q.v.*), and the native Scythians and Tauri, and even extending its power over the west coast of the peninsula, it was compelled to call in the aid of Mithradates VI. and his general Diophantus, c. 110 B.C., and submitted to the Pontic dynasty. On regaining a nominal independence, it came more or less under the Roman suzerainty. In the latter part of the 1st century A.D., and again in the second, it received a Roman garrison and suffered much interference in its internal affairs. In the time of Constantine, in return for assistance against the Bosphorans and the native tribes, it regained its autonomy and received special privileges. It must, however, have been subject to the Byzantine authorities, as inscriptions testify to restorations of its walls by Byzantine officials. Under Theophilus the central government sent out a governor to take the place of the elected magistrate. Even so it seems to have preserved a measure of self-government and may be said to have been the last of the Greek city states. It had been the main emporium of Byzantine commerce upon the north coast of the Euxine. Through it went the communications of the empire with the Petchenegs and other native tribes, and more especially with the Russians. The commerce of Cherson is guaranteed in the early treaties between the Greeks and Russians, and it was in Cherson, according to Pseudo-Nestor's chronicle (see *Nestor*), that Vladimir was baptized in 988 after he had captured the city. Its ruin was brought about by the commercial rivalry of the Genoese, who forbade the Greeks to trade there and diverted its commerce to Caffa and Sudak. The constitution of the city was at first democratic under *damiorgi*, a senate and a general assembly. Latterly it appears to have become aristocratic, and most of the power was concentrated in the hands of the first archon or *proteuon*, who in time was superseded by the *strategus* sent out from Byzantium. Its most interesting political document is the form of oath sworn by all citizens in the 3rd century B.C.

Remains.—The remains of the city occupy a space about two-thirds of a mile long by half a mile broad, enclosed by a Byzantine wall. Remains of a Greek wall going back to the 4th century B.C. have been found beneath this in the eastern or original part of the site. Many Byzantine churches, both cruciform and basilican, have been excavated. The latter survived here into the 13th century when they had long been extinct in other Greek-speaking lands. The churches were adorned with frescoes, wall and floor mosaics, and marble carvings similar to work found at Ravenna. The fact that the site has not been inhabited since the 14th century makes it important for our knowledge of Byzantine life. The city was used by the Romans as a place of banishment: St. Clement of Rome was exiled hither and first preached the Gospel; another exile was Justinian II., who is said to have destroyed the city in revenge. Its coins range from the 3rd century B.C. to about A.D. 200, and there are Byzantine issues.

See B. Koehne, *Beiträge zur Geschichte von Cherronesus in Taurien* (St. Petersburg, 1848); art. "Chersonesos" (20) by C. G. Brandis in Pauly-Wissowa, *Realencyklopädie*, vol. iii. 221; A. A. Bobrinskoi, *Chersonesus Taurica* (St. Petersburg, 1905) (Russian); V. V. Latyshev, *Inscr. Orae Septentr. Ponti Euxini*, vols. i. and iv. Reports of excavations appear in the *Compte rendu* of the Imperial Archaeological Commission of St. Petersburg from 1888 and in its *Bulletin*. See also E. H.

CHERT, in geology, a rock consisting mainly of silica in a finely granular or chalcedonic form, closely allied to flint (*q.v.*). Cherts are probably formed in several different ways; for example, by solution and re-deposition of the silica contained in the spicules of sponges and other siliceous organisms in sedimentary rocks, such as the Carboniferous limestone and Upper Greensand of England; by accumulation on the floor of the sea in ancient times of radiolaria and diatoms, like some of the modern deep-sea deposits; by precipitation of silica from magmatic solutions belonging to the later stages of submarine volcanic eruptions. In some instances it is uncertain which of these causes was concerned in their formation. Cherts rich in compounds of iron, of volcanic origin, were the primary source of the iron ore of the Lake Superior region of the United States. The Rhynie cherts of Devonian age, in Scotland, are noteworthy for the remarkable preservation of the minute details of the structure of fossils embedded in them. (R. H. RA.)

CHERTSEY, urban district of Surrey, England, 22 m. S.W. of London by the S.R. Pop. (1931) 17,130. It is pleasantly situated on the right bank of the Thames, which is crossed by a bridge of seven arches, built of Purbeck stone in 1785.

The first religious settlement in Surrey, a Benedictine abbey, was founded in 666 at Chertsey (*Cerotesei*, *Certesey*), the manor of which belonged to the abbot until 1539, since when it has been a possession of the crown. In the reign of Edward the Confessor Chertsey was a large village and was made the head of Godley hundred. Chertsey owed its importance primarily to the abbey, but partly to its geographical position. Ferries over the Redewynd were subjects of royal grant in 1340 and 1399; the abbot built a new bridge over the Bourne in 1333, and wholly maintained the bridge over the Thames when it replaced the 14th century ferry. In 1410 the king gave permission to build a bridge over the Redewynd. As the centre of an agricultural district the markets of Chertsey were important and are still held.

Three days' fairs were granted to the abbots in 1129 for the feast of St. Peter ad Vincula by Henry III. for Holy Rood day; in 1282 for Ascension day; and a market on Mondays was obtained in 1282.

Little remains of the abbey buildings, which fell into decay in the 17th century. The ground-plan, however, can be traced and the fish-ponds are complete. Among the abbots the most famous was John de Rutherwyk, who was appointed in 1307, and continued, till his death in 1346, to carry on a great system of alteration and extension. The house in which the poet Cowley spent the last years of his life remains. The town is the centre of a large residential district. Its principal trade is in produce for the London markets.

See Lucy Wheeler, *Chertsey Abbey* (London, 1905); *Victoria County History*, Surrey.

CHERUBIM are winged creatures associated in the Old Testament with the deity. The name, plural of the Hebrew *kērūb*, has no Hebrew etymology, and was taken over, with the conception, from older sources. Similar creatures are found in other oriental religions. The cherubim who guard Paradise (Gen. iii. 24) are introduced, without description, as well-known figures. The cherub appears also in Ezek. xxviii. 13-16, behind which passage lies another version of the Paradise story, but the text is too obscure to throw much light on his character. More illuminating is the vision of Ezekiel, ch. i., where the four "living creatures" attendant upon the divine chariot are undoubtedly cherubim, for they are expressly so named in Ezek. x. These have each four wings, and four faces—those of a man, a lion, an ox, an eagle. The two seraphim of Isa. vi. belong to the same category, though these have six wings and, presumably, human faces. In Ezekiel and Isaiah these beings are connected with the divine throne. It is thus natural that we should find two gold cherubim covering the "mercy-seat" (Exod. xxxvii. 6-9, xxv. 18-22). Representations of cherubim are found also in the hangings of the shrine (Exod. xxvi. 1, 31), and figures of two cherubim, overlaid with gold, in Solomon's temple (1 Ki. vi. 23-28, viii. 6 seq.), others carved on

the walls (vi. 29-32), and about the bases of the "molten sea" (vii. 29). So the temple of Ezekiel has carved decorations of cherubim, these with two faces, a man's and a lion's (xl. 18 seq.). The description of Yahweh riding "upon a cherub," Ps. xviii. 10, has for its parallel "upon the wings of the wind"; this, although in Babylonian myth the south wind has wings that can be broken, suggests that a mythological conception is used merely for poetical effect, a conclusion confirmed by the similar passage Ps. civ. 3, in which the cherub is replaced by clouds.

To sum up, the cherubim are hybrid creatures, with wings of birds, human or animal faces, regarded as attendants upon the divine throne, or guardians of specially sacred places. The four "living creatures" of Rev. iv. 6 are lineal descendants of those in Ezekiel's vision. In Jewish literature the cherubim appear as a class of angels. Representations of figures similar to the Old Testament cherubim have been discovered in many places, a pair from Dendera showing striking resemblance to those described in Exodus.

See the illustrations in Gressmann's *Altorientalische Texte und Bilder zum Alten Testamente*, nos. 378 seq.; Vincent, *Revue Biblique*, p. 487 seq. (1926). (W. L. W.)

CHERUBINI, MARIA LUIGI CARLO ZENOBIA SALVATORE (1760-1842), Italian musical composer, was born at Florence on Sept. 14, 1760, and died on March 15, 1842 in Paris. His father was *Maestro al Cembalo* at the Pergola theatre, and began to teach him music when he was six. By the time he was 16 he had composed a great deal of Church music, and in 1777 he went to Bologna, where for four years he studied under Sarti. This famous master well earned the gratitude which afterwards impelled Cherubini to place one of his double choruses by the side of his own *Et Vitam Venturi* as the crown of his *Treatise on Counterpoint and Fugue*, though the juxtaposition does Sarti's music no good. Cherubini also worked at operatic composition, and Sarti sometimes, like the great masters of painting, entrusted his pupil with minor parts of his own works. Cherubini's first complete opera, *Quinto Fabio* was produced in 1780 and was followed in 1782 by *Armida*, *Adriano in Siria*, and other works. In 1784 he was invited to London to produce two works for the Italian opera there, one of which, *La Finta Principessa*, was favourably received while the other, *Giulio Sabino*, was, according to a contemporary witness, "murdered" by the critics.

In 1786 he left London for Paris, which became his home after a visit to Turin in 1787-88 on the occasion of the production there of his *Ifigenia in Aulide*. His first French opera, *Démophon* (1788), which was not a popular success, already marks a departure from the Italian style, which Cherubini still cultivated in the pieces he introduced into the works of Anfossi, Paisiello and Cimarosa, produced by him as director of the Italian opera in Paris (established in 1789). In Paris Cherubini became a great composer. If his melodic invention had been as warm as Gluck's, his masterly technique would have made him one of the greatest composers that ever lived. But his personal character shows in its Johnsonian "antracuosities" an un-Johnsonian "unclubability," which extends to the centre of his art and deprives even his finest music of the glow of inspiration that fears nothing.

With *Lodoiska* (1791) the series of Cherubini's master-pieces begins, and *Médée* (1797) shows his full powers. Cherubini's creative genius was never more brilliant than at this period, as the wonderful two-act ballet, *Anacreon*, shows; but his temper and spirits were not improved by a series of disappointments which culminated in the collapse of his prospects of congenial success at Vienna, where he went in 1805 in compliance with an invitation to compose an opera for the Imperial theatre. Here he produced, under the title of *Der Wasserträger*, the great work which, on its first production on January 7, 1801 (26 *Nivôse*, An 8) as *Les Deux Journées*, had thrilled Paris with the accents of a humanity restored to health and peace. It was by this time an established favourite in Austria. On February 25 Cherubini produced *Faniska*, but the war between Austria and France had broken out immediately after his arrival, and the run of *Faniska* was stopped by the bombardment and capitulation of Vienna.

His stay at Vienna is memorable for his intercourse with Beethoven, the most whole-hearted admirer he and his works have ever met in a century and a quarter. The mighty genius of Beethoven, which broke through all rules in vindication of the principles underlying them, was incomprehensible to Cherubini, in whose mind the creative faculties were finely developed, but whose critical faculty was supplanted by a mere disciplinary code inadequate even as a basis for the analysis of his own works. On the other hand, it would be impossible to exaggerate the influence *Les Deux Journées* had on the lighter parts of Beethoven's *Fidelio*. Cherubini's librettist was also the author of the libretto from which *Fidelio* was adapted, and Cherubini's score was a constant object of Beethoven's study, not only before the production of the first version of *Fidelio* (as *Leonore*) but also throughout Beethoven's life. Cherubini's record of Beethoven's character is contained in the single phrase, "Il était toujours brusque," a fine example of the pot's opinion of the kettle. The overture to *Leonore* merely puzzled Cherubini as to what key it might be in. Beethoven's brusqueness did not prevent him from assuring Cherubini that he considered him the greatest composer of the age and that he loved and honoured him. Cherubini's incapacity to understand Beethoven did not prevent him from working on the grand scale which Beethoven had by that time established as a permanent standard for musical art. The colossal breadth of the duet *Perfides ennemis* in *Médée* is almost inconceivable without the example of Beethoven's C minor trio, op. 1, No. 3, published two years before it. On the other hand the cavatina *Eterno iddio* in *Faniska* is of a terseness and depth not only worthy of Beethoven but surprisingly like him in style.

After Cherubini's disappointing visit to Vienna he did little until 1809 when his friends with much difficulty persuaded him to write a mass for the consecration of a church at the country seat of the prince de Chimay, where he was staying. With this mass (in F, for three-part chorus and orchestra), the period of his great Church music begins; although it was by no means the end of his career as an opera writer, which lasted as late as his 73rd year (1832). This third period is also marked by several instrumental compositions. An early event in the annals of the Philharmonic Society was the invitation of Cherubini to London in 1815 to produce a symphony, an overture and a vocal piece. The symphony (in D) was afterwards arranged, with a new slow movement, as the string quartet in C (1829), a curious illustration of Cherubini's notions of symphonic as well as of chamber-music style, for the quartet-writing is just like that of his other quartets; oil-painting restricted to black and white. Nevertheless the first three of the six string quartets written between 1814 and 1837 are interesting works performed with success at the present day, and the last three, discovered in 1889 are not without fine passages.

At the eleventh hour Cherubini received recognition from Napoleon, who, during the Hundred Days, made him chevalier of the Legion of Honour. Then, with the restoration of the Bourbons, Cherubini's position improved. He was appointed, jointly with Lesueur, as composer and conductor to the Chapel Royal, and in 1822 he obtained the permanent directorship of the conservatoire.

In 1833 Cherubini produced his last work for the stage, *Ali Baba*, adapted (with new and noisy features which excited Mendelssohn's astonished disgust) from a manuscript opera, *Koukourgi*, written 40 years earlier. It is therefore not one of the brighter rockets from what Mendelssohn called "the extinct volcano." But the requiem in D minor (for male voices), written in 1836, is one of Cherubini's greatest works, and, though not actually his last composition, is a worthy close to the long career of an artist of high ideals who, while neither by birth nor temperament a Frenchman, must yet be counted with a still greater foreigner, Gluck, as among the glories of French classical music. Cherubini's *Treatise on Counterpoint and Fugue* embodies his views as a theorist. Concerning one 16th century idiom, as natural in pure polyphony as "attraction of the relative" is in classical Greek. Cherubini remarks, "No tradition gives us any reason why the classics thus faultily deviated from the rule." On

another point where there is a fine opportunity for stimulating a sense of harmonic values, he inculcates a mechanical pseudologic with the remark that "The opinion of the classics appears to me erroneous, notwithstanding that custom has sanctioned it, for on the principle that the discord is a mere suspension of the chord, it should not affect the nature of the chord. But since the classics have pronounced judgment we must of course submit." On the whole Cherubini's career as a teacher did more harm than good in his lifetime, and his *Treatise on Counterpoint and Fugue* continues at the present day to invest disastrous misinterpretations of classical art forms with the authority of a great composer.

And yet as a composer Cherubini was no pseudo-classic but a really great artist. His purity of style rarely joined itself to matter that could express the ideals he kept always in view. In his love of those ideals there was too much fear: but Beethoven's estimate of him is more just than the contemptuous neglect with which his art is treated now.

His principal works are summarized by Fétis as 32 operas, 29 Church compositions, four cantatas and several instrumental pieces, besides the treatise on counterpoint and fugue.

Good modern full scores of the two Requiems and of *Les Deux Journées* (the latter unfortunately without the dialogue, which, however, is accessible in a careful German translation in the *Reclam Bibliothek*), and also of ten opera overtures, are current in the Peters edition. Vocal scores of some of the other operas are not difficult to get. The great Credo is in the Peters edition, but is becoming scarce. The string quartets are in Payne's *Miniature Scores*. It is very desirable that the operas, from *Démophon* onwards, should be republished in full score.

CHÉRUEL, PIERRE ADOLPHE (1809-1891), French historian, was born at Rouen. His most important work was done on the history of France in the 17th century. Among his books are *Histoire de l'administration monarchique en France depuis l'avènement de Philippe-Auguste jusqu'à la mort de Louis XIV.* (1855); *Dictionnaire historique des institutions, mœurs et coutumes de la France* (1855); *Journal d'Olivier Lefèvre d'Ormesson* (1860-62); editions of the *Lettres du cardinal Mazarin pendant son ministère* (6 vols., 1870-91), continued by the vicomte G. d'Avenel; of the *Mémoires du duc de Saint-Simon* (1856-58 and 1878-81); *Notice sur la vie et sur les mémoires du duc de Saint-Simon* (1876); *Histoire de la France pendant la minorité de Louis XIV.* (4 vols., 1880) and *Histoire de la France sous le ministère de Mazarin* (3 vols., 1882-83).

CHERUSCI, an ancient German tribe occupying the basin of the Weser to the north of the Chatti (*q.v.*). Together with the other tribes of western Germany they submitted to the Romans in 11-9 B.C., but in A.D. 9 Arminius, one of their princes, rose in revolt, and defeated and slew the Roman General Quintilius Varus, annihilating his army. Germanicus Caesar (*q.v.*) made several unsuccessful attempts to bring them into subjection again. By the end of the 1st century A.D. their prestige had declined, and their territory was eventually occupied by the Saxons.

CHERVONETZ, the new Russian monetary unit, instituted in 1922 as part of the New Economic Policy. The old pre-World War rouble had, owing to heavy war expenditure, the military-Communist era of 1917-22 and to post-war heavy budget deficits (balanced deliberately by fresh note emissions), depreciated to vanishing point. When the Soviet Government realized the need of a stable currency they instituted the chervonetz.

The chervonetz equals 10 pre-war roubles or 2s. 1½d. Chervonetz notes were issued by the new State bank, having a backing of 25% in gold, platinum or stable foreign exchange, the remaining 75% cover to consist of marketable goods, short-term securities or approved bills of exchange. These notes were from their inception restricted in their issue, so as to maintain the above

provisions, and in particular steps were taken to discourage them from entering into internal circulation. They were used as the basis of the nation's currency system and foreign exchange rates were quoted in chervontsi.

Side by side with the chervonetz a new series of rouble notes was issued intended for internal use. These had no fixed conversion ratio against the chervonetz, and for the two years immediately succeeding their first appearance they were issued freely to balance successive budget deficits. Hence they in turn rapidly depreciated until the conversion ratio reached the astronomical figure of 200,000,000,000 roubles to one chervonetz.

In 1924 it proved possible to balance the budget and so to reorganize the internal currency. New currency rouble notes were issued, their volume being limited to half that of the chervontsi in circulation. Simultaneously the old Soviet or 1923 roubles were gradually withdrawn. Since 1924 the internal currency has consisted of stable rouble, currency notes and subsidiary coins. (See also CURRENCY, ROUBLE.)

CHESAPEAKE AND DELAWARE CANAL, in the United States, connects Chesapeake City, Md., and Delaware City, Del., and provides a water route directly across Delaware and Maryland from Delaware bay to Chesapeake bay. It is 14 m. long, 90 ft. wide and 12 ft. in depth. The cost of construction was approximately \$10,000,000.

CHESAPEAKE AND OHIO CANAL, in the United States, connects Cumberland, Md., with Washington, D.C., and is used largely for the transportation of coal from the Cumberland region to the Potomac river. It has 73 locks, gaining an elevation of 609 feet. The cost of construction with improvements was about \$14,000,000. It is 184 m. long, 68 ft. wide and 6 ft. in depth with capacity for canal boats of 180 tons.

CHESAPEAKE AND OHIO RAILWAY COMPANY.

The Chesapeake and Ohio was incorporated in 1868, a consolidation of two local lines, the Virginia Central and the Covington and Ohio, originally started to give the State of Virginia a western outlet for its products. Since that time the company twice has been in receivership and has undergone several important shifts of control, dominated by different powerful financial groups of interests. Its control is now in the hands of O. P. and M. J. Van Sweringen. It is one of the great trunk lines and coal-carrying railroads, piercing the heart of the rich non-union bituminous fields of West Virginia and Kentucky. Over four-fifths of the company's traffic originates on its own lines. The Chesapeake and Ohio operates 2,705 m. of railroad, extending in a north-western direction from Newport News, on Hampton Roads, Va., to Louisville, Ky., and through Cincinnati to Chicago, on Lake Michigan. Over its subsidiary, the Hocking Valley, it reaches Toledo on Lake Erie. Thus the company has two outlets, East and West. East-bound traffic is for reshipment by water to European markets and North Atlantic ports; the west-bound traffic goes through the Great Lakes to the North-western States. Cost of road and equipment on Dec. 31, 1927 was \$371,957,251.64. In 1927 the operating revenues were \$133,042,174; operating expenses, \$89,733,037; operating ratio, 67.7%; net railway operating income, \$36,320,830; other income, \$2,092,324; total income, \$38,413,154; fixed charges, \$9,805,839; surplus after charges \$28,607,315.

(W. J. HA.)

CHESELDEN, WILLIAM (1688-1752), English surgeon, was born at Somerby, Leicestershire, on Oct. 19, 1688. He studied anatomy in London under William Cowper (1666-1709), and in 1713 published his *Anatomy of the Human Body*. He became surgeon at St. Thomas's and St. George's hospitals, London. Cheselden is famous for his "lateral operation for the stone," which he first performed in 1727. He also effected a great advance in ophthalmic surgery by his operation of iridectomy, described in 1728, for the treatment of certain forms of blindness by the production of an "artificial pupil." He attended Sir Isaac Newton in his last illness, and was a friend of Alexander Pope and of Sir Hans Sloane. He died at Bath on April 10, 1752.

CHESHAM, an urban district and market town of Buckinghamshire, England, 26 m. W.N.W. of London by the Met. and G.C.R. Pop. (1931) 8,809. It is pleasantly situated in the narrow

valley of the river Chess, flanked by low wooded chalk hills. The church of St. Mary, which has some ancient frescoes, is cruciform and mainly Perpendicular in style. Dairy utensils, chairs, malt-shovels, etc., are made of beech. Shoemaking is also carried on. Waterside, adjoining the town, has duck farms and extensive watercress beds, for which the Chess is noted.

CHESHIRE, a north-western county of England, bounded north by Lancashire, north-east by Yorkshire and Derbyshire, south-east by Staffordshire, south by Shropshire, west by Denbighshire and Flint, and north-west by the Irish Sea. Area, 1027·8 sq. m. The coast-line is formed by the estuaries of the Dee and the Mersey, which are separated by the low rectangular peninsula of Wirral. The Dee forms a great part of the county boundary with Denbighshire and Flint, and the Mersey the boundary along the whole of the northern side. The principal river within the county is the Weaver, which crosses it on a north-westerly course, and receiving the Dane at Northwich, discharges into the estuary of the Mersey south of Runcorn. The surface of Cheshire is mostly low and gently undulating or flat: the broken line of the Peckforton hills, seldom exceeding 600 ft. in height, is conspicuous. The northern part of the hills coincides approximately with the district called Delamere Forest, formerly a chase of the earls of Chester, and finally disforested in 1812. Southwards, commanding the narrow gap of the Gowy river on the west stands the Norman castle of Beeston. Distributed over the county, but principally in the eastern half, are many small lakes or meres, such as Combermere, Tatton, Rostherne, Tabley, Doddington, Marbury and Mere.

With the exception of some Carboniferous rocks on the eastern border, and a small patch of Lower Lias near Audlem, the whole county is occupied by Triassic strata. The great central plain is covered by Keuper Marls, rich grassland loams with many beds of rock-salt, mostly thin, though two are from 75 ft. to over 100 ft. thick. Thin beds and veins of gypsum are common in the marls. The striking features of the Peckforton Hills, which run north and south, bordering the valley of the Weaver on the west, are due to the repeated faulting of the Lower Keuper Sandstone, which lies upon beds of Bunter Sandstone. Besides forming this well-marked ridge, the Lower Keuper Sandstone, which is quarried in several places, forms several ridges north-west of Macclesfield and appears along the northern border and in the neighbourhood of New Brighton and Birkenhead. It is a good building stone and an important water-bearing stratum. At Alderley Edge ores of copper, lead and cobalt are found. West of the Peckforton ridge, Bunter Sandstones and pebble beds extend to the border. They also form low foothills between Cheadle and Macclesfield. They fringe the northern boundary and appear on the south-eastern boundary as a narrow strip of hilly ground near Woore. From Macclesfield northward through Stockport is a narrow tongue of coal-measures—an extension of the Lancashire coalfield. Coal is mined at Neston in the Wirral peninsula from beneath the Trias; it is a connecting link between the Lancashire and Flintshire coalfields. Glacial drift with northern erratics is thickly spread over all the lower ground; at Crewe the drift is over 400 ft. thick. Patches of drift sand, with marine shells, occur on the high ground east of Macclesfield at an elevation of 1,250 ft. The Cheshire lowland filled with prehistoric swamp and forest has not yielded large finds of ancient objects. A list of perforated stone axes is given in *Trans. Lancs. and Ches. Ant. Soc.*, vol. v., p. 327 (see also vol. xi., p. 171). Tranmere has yielded a stone-celt retaining part of its wooden handle. Copper was mined at some early period at Alderley Edge and stone hammers with a groove for attachment occur here. The type occurs in Shetland, Wales, South-West Ireland, Brittany, the Iberian Peninsula, Savoy, Austria and Egypt; it is well-known in the New World and the Cambridge Museum has specimens from Australia. A flat celt of copper or bronze is known from Grappenhall. Broxton has yielded one of the few trunnion celts of Britain (see Hemp, W. J. *Antiq. Journ.*, vol. v, 1925, p. 51) together with two palstaves and a spearhead. A dagger blade and a pommel have been found at Wilmslow and the surface of the upper Forest bed at Meols has yielded antiquities apparently of the Early Iron Age.

History.—The earliest recorded historical fact is the capture of Chester by the Northumbrian king Aethelfrith about 614. After a period of incessant strife between Britons and Saxons the district was subjugated in 830 and incorporated in the kingdom of Mercia. During the 9th century Aethelwulf held his parliament at Chester, and received the homage of his tributary kings from Berwick to Kent, and in the 10th century Aethelflaed rebuilt the city, and erected fortresses at Eddisbury and Runcorn. Edward the Elder garrisoned Thelwall and strengthened the passages of the Mersey and Irwell. On the splitting up of Mercia in the 10th century the dependent districts along the Dee were made a shire for the fortress of Chester. The shire is first mentioned in the *Abingdon Chronicle*, which relates that in 980 Cheshire was plundered by a fleet of Northmen. At the time of the Domesday survey the county was divided into twelve hundreds, exclusive of the six hundreds between the Ribble and the Mersey, now included in Lancashire, but then a part of Cheshire. Of the seven modern hundreds Bucklow alone retains its Domesday name. The hundreds of Atiscross and Exestan have been transferred to the counties of Flint and Denbigh, with the exception of a few townships now in the hundred of Broxton. Cheshire put up a determined resistance to the Conqueror and no Englishman retained estates of importance after the Conquest. It was constituted a county palatine, with an independent parliament consisting of the barons and clergy, and courts and all lands except those of the bishop were held of the earl. During the 12th and 13th centuries the county was impoverished by the constant inroads of the Welsh. In 1264 the castle and city of Chester were granted to Simon de Montfort. Richard II., in return for support made the county a principality, but the act was revoked in the next reign. In 1403 Cheshire was the headquarters of Hotspur. At the beginning of the Wars of the Roses Margaret collected a body of supporters from among the Cheshire gentry, and Lancastrian risings occurred as late as 1464. In 1643, Chester was made the headquarters of the royalist forces, while Nantwich was garrisoned for the parliament, and the county became the scene of constant skirmishes until the surrender of Chester in 1646.

In the reign of Henry VIII. the distinctive privileges of Cheshire as a county palatine were abridged. The right of sanctuary attached to the city of Chester was abolished and justices of peace were appointed as in other parts of the kingdom. An impression of the wealth of the rich agricultural county is to be seen in the numerous half-timbered houses and ancient manor-houses such as Bramhall Hall, near Macclesfield and Moreton Old Hall, near Congleton. The former dates from the 13th and 14th centuries, and contains a handsome panelled hall. Moreton Hall and several others, such as Brereton and Dorfold Halls, are Elizabethan. Vale Hall near Winsford incorporates fragments of a Cistercian monastery founded in 1277. Ecclesiastical architecture is not well represented outside Chester (*q.v.*), but Lower Peover, near Knutsford has a notable half-timbered church of 13th century date, restored in 1852. There is also a fine late Perpendicular church (with earlier portions) at Astbury near Congleton, and the churches of Banbury and Malpas are Perpendicular and Decorated. St. Michael's church and the Rivers chapel at Macclesfield are noteworthy. In the market-place at Sandbach are two remarkable sculptured Saxon crosses.

Agriculture and Industries.—From earliest times the staple products of Cheshire have been salt and cheese. The salt-pits of Nantwich, Middlewich and Northwich were in active operation at the time of Edward the Confessor, and at that date the mills and fisheries on the Dee also furnished a valuable source of revenue. Twelfth century writers refer to the excellence of Cheshire cheese. The trades of tanners, skinners and glove-makers existed at the time of the Conquest, and the export trade in wool in the 13th and 14th centuries was considerable. The soil of the county is varied and irregular; a large proportion is clay. Nearly 80% of the total area is under cultivation. Oats are by far the most important cereal, and nearly 50% of the cultivated land is in permanent pasture. The vicinity of such populous centres as Liverpool and Manchester stimulates dairy,

ing. The name of the county is given to a particular brand of cheese (*see* DAIRY). Potatoes are by far the most important root-crop. The damson is common among fruit-trees, while the strawberry beds near Farndon and Holt are celebrated. Market-gardening is pursued in the neighbourhoods of Chester, Wallasey and Altrincham. In the first half of the 19th century the condition of agriculture in Cheshire was notoriously backward. In 1865–1866 the county suffered from cattle plague, and at various times since diseases introduced from overseas through Liverpool have ravaged the county. The manufacture of textiles extends from its seat in Lancashire into Cheshire; and the whole north-eastern tongue of the county is engaged in branches of the industry, particularly cotton-spinning. Metal working is important, and embraces ship-building (Birkenhead) and galvanized iron products (Ellesmere Port). At Crewe are situated the great workshops of the London, Midland and Scottish railway company, to which the town owes its origin and rise. Chemical industries are of special importance, and are found along the Mersey; they are closely related to the salt industry. The Mersey shore also has machinery and iron works, flour-mills, tobacco and soap-works (Port Sunlight). Much sandstone is quarried, but the mineral wealth of the county lies in coal (around Congleton and Macclesfield) and especially salt. Some rock-salt is obtained at Northwich and Winsford, but most of the salt is extracted from brine both here and at Lawton, Wheelock and Middlewich. Subsidence frequently occur after the brine is pumped out; walls crack and collapse, and houses are seen leaning far out of the perpendicular.

Communications.—The county is well served with railways. The main line of the L.M.S.R. runs north from Crewe to Warrington with branches from Crewe diverging fanwise to Manchester, Chester, North Wales and Shrewsbury. The G.W.R. passes northward from Wrexham to Liverpool and Manchester. The heart of the county is traversed by the Cheshire Lines, serving the salt district, and reaching Chester from Manchester by way of Delamere Forest. In the west, between Chester, Connah's Quay and Liverpool, the L.N.E.R. operates. The county possesses numerous first class roads, and many experiments in road building have been made in the Wirral. The river Weaver is locked as far up as Winsford, and the transport of salt is thus expedited. The profits of the navigation, which was originally undertaken in 1720 by a few Cheshire squires, belong to the county, and are paid annually to the relief of the county rates. In the salt district of the Weaver, subsidence has resulted in the formation of lakes of considerable extent, which act as reservoirs to supply the navigation. Inland navigation is also provided by the Grand Trunk, Shropshire Union and other canals, and many small steamers are in use. The Manchester Ship Canal passes through a section of north Cheshire, entering from the Mersey estuary by locks near Eastham, and following its southern shore up to Runcorn, after which it takes a course more direct than the river, and finally enters Lancashire at the junction of the Irwell with the Mersey, near Irlam.

Population and Administration.—The area of the administrative county (with county boroughs) is 652,383 acres; pop. (1931) 1,087,544. Cheshire has been described as a suburb of Liverpool, Manchester and the Potteries, and has been freely colonized from these populous industrial centres. On the short sea coast of the Wirral are found the popular resorts of New Brighton and Hoylake. The movement of population and the importance of the industries of the county have brought about a vast increase of population in modern times. The county contains 7 hundreds. The municipal boroughs are Birkenhead (pop. 147,946), Chester (41,438), Congleton (12,885), Crewe (46,061), Dukinfield (19,309), Hyde (32,066), Macclesfield (34,902), Stalybridge (24,823), Wallasey (97,465) and Stockport (125,505). Chester, the county town, is a city and county borough, and Birkenhead, Wallasey and Stockport are county boroughs.

The county is in the North Wales and Chester circuit, and assizes are held at Chester. It has one court of quarter sessions, and is divided into fourteen petty sessional divisions. There are 464 civil parishes. Cheshire is almost wholly in the diocese of Chester, but small parts are in those of Manchester, St. Asaph

or Lichfield. There are 268 ecclesiastical parishes or districts wholly or in part within the county. There are nine parliamentary divisions, namely Macclesfield, Crewe, Eddisbury, Wirral, Knutsford, Altrincham, Northwich, City of Chester, Stalybridge and Hyde; the county also includes the parliamentary borough of Birkenhead, returning two members, the borough of Wallasey and parts of the borough of Stockport, which returns two members, and of Ashton-under-Lyne, and Warrington, which return one member each.

CHESHUNT, an urban district of Hertfordshire, England, on the Lea, 16m. N. of London by the L.N.E.R. Pop. (1931) 14,651. Finds indicate the presence of a Romano-British settlement. There was a Benedictine nunnery here in the 13th century. A mansion in the vicinity, the Great House, belonged to Cardinal Wolsey, and a former Pengelly House was the residence of Richard Cromwell the Protector after his resignation. Theobalds Park was built in the 18th century. James I. died here in the original mansion in 1625, and Charles I. set out from here for Nottingham in 1642 at the outset of the Civil War. One of the entrances to Theobalds Park is old Temple Bar, moved from Fleet street, London, 1878. The church of St. Mary is Perpendicular, with modern additions. Cheshunt college (1792), reorganized and removed to Cambridge in 1905, was the successor of a college founded by the countess of Huntingdon in 1768 at Trevecca in Brecknockshire for the education of ministers of the Methodist Connexion. Cheshunt is an important centre of market gardening.

CHESIL BANK (A.S., *ceosol*, pebble bank), a remarkable beach of shingle on the coast of Dorsetshire, England. It is separated from the mainland for 8m. by an inlet called the Fleet, famous for its swannery, and continues in all for 18m. south-eastward from near Abbotsbury, terminating at the so-called isle of Portland. At the Portland end it is 35ft. above spring-tide level, and 200yd. wide; while at the landward end the width is 170yd. and the pebbles decrease in size. This accords with the general movement of shingle along this coast from west to east.

CHESNELONG, PIERRE CHARLES (1820–1899), French politician, was born at Orthez, Basses Pyrénées. A member of the chamber of deputies from 1865–76, with a short interval in 1870–72, he was an uncompromising clericalist and, after 1870, a Legitimist. He was the soul of the reactionary opposition that led to the fall of Thiers; and in 1873 it was he who, with Lucien Brun, carried to the comte de Chambord the proposals of the chambers. Through some misunderstanding, he reported on his return that the count had accepted all the terms offered, including the retention of the tricolour flag; and the count published a formal denial. Chesnelong now devoted himself to the establishment of Catholic universities and to the formation of Catholic working-men's clubs. He continued his vigorous polemic against the secularization of the educational system of France from his place in the senate, to which he was elected in Nov. 1876.

See M. de Marcey, *Charles Chesnelong*, etc. 3 vols. (1908); Mgr. Laveille, *Chesnelong, sa vie, son action catholique et parlementaire* (1913).

CHESNEY, CHARLES CORNWALLIS (1826–1876), British soldier and military writer, the third son of Charles Cornwallis Chesney, Bengal Artillery, and nephew of Gen. F. R. Chesney, was born in Co. Down, Ireland, on Sept. 29, 1826. Educated

at Blundell's school, Tiverton, and afterwards at the Royal Military academy, Woolwich, he passed out of the academy in 1845 at the head of his term. In 1858 Capt. Chesney was appointed professor of military history at Sandhurst. In 1864 he succeeded Col. (afterwards Sir Edward) Hamley in the corresponding chair at the Staff college. Chesney's first published work (1863) was an account of the civil war in Virginia, which went through several editions. But the work which attained the greatest reputation was his *Waterloo Lectures* (1868). Chesney's account illustrates both the strategy and tactics which culminated in the final catastrophe and the mistakes committed by Napoleon, and for the first time an English writer is found to point out that the dispositions of Wellington were far from faultless. In the *Waterloo Lectures* the Prussians are for the first time credited by an English pen with their proper share in the victory. In 1868 Chesney was appointed a member of the royal commission on military education, to whose recommendations were due the improved organization of the military colleges, and the development of military education in the principal military stations of the British army. In 1871 he was sent on a special mission to France and Germany, and wrote a series of valuable reports on the different siege operations during the war, especially the two sieges of Paris. He was consulted by officers of all grades on professional matters, and few have done more to raise the intellectual standard of the British officer. He died on March 19, 1876.

CHESNEY, FRANCIS RAWDON (1789-1872), British general and explorer, the son of Capt. Alexander Chesney, was born at Annalong, Co. Down, Ireland, on March 16, 1789. He received a cadetship at Woolwich, and was gazetted to the Royal Artillery in 1805. But though he rose to be colonel-commandant of the 14th brigade Royal Artillery (1864), and general in 1868, Chesney is chiefly remembered for his connection with the Suez canal, and with the exploration of the Euphrates valley. His report in 1830 on the feasibility of making the Suez canal was the basis of Lesseps' great undertaking. In 1831 he introduced to the home Government the idea of opening a new overland route to India by a daring journey along the Euphrates from Anah to the Persian gulf. In 1835 he was in command of a small expedition for which parliament voted £20,000 to test the navigability of the Euphrates. After encountering difficulties from the opposition of the Egyptian pasha, and from the need of transporting two steamers (one of which was lost) in sections from the Mediterranean over the hilly country to the river, they arrived by water at Bushire in the summer of 1836, and proved Chesney's view to be practicable. In 1847 his period of service was completed, and he went home to Ireland, but in 1856 and again in 1862 he went out to the East to take a part in further surveys and negotiations for the Euphrates valley railway scheme. He died on Jan. 30, 1872.

The chief works of Chesney are: *The Expedition for the Survey of the Rivers Euphrates and Tigris* (1850); *Observations on . . . Fire-arms* (1852); *The Russo-Turkish Campaigns of 1828 and 1829* (1854); *Narrative of the Euphrates Expedition* (1854). See *The Life of Gen. F. R. Chesney* by his wife and daughter, ed. S. Lane-Poole (1885).

CHESNEY, SIR GEORGE TOMKYN (1830-1895), English general, brother of Col. C. C. Chesney, was born at Tiverton (Devon), on April 30, 1830. Educated at Blundell's school, Tiverton, and at Addiscombe, he entered the Bengal Engineers as second lieutenant in 1848. After some years in the public works department he earned distinction in the Indian Mutiny and was severely wounded in the assault of Delhi. The originator of the Royal Indian civil engineering college at Cooper's hill, Staines, he was also its first president (1871-80). In 1871 he contributed to *Blackwood's Magazine* "The Battle of Dorking," a vivid account of a supposed invasion of England by the Germans after their victory over France. This was republished in many editions and translations, and produced a profound impression. He was promoted major-general in 1886, and general in 1892. From 1886 to 1892, as military member of the governor-general's council, he carried out many much-needed military reforms. In that year he became Conservative M.P. for Oxford, and was chairman of the committee of service members of the House of Com-

mons until his death on March 31, 1895. He wrote some novels, *The Dilemma*, *The Private Secretary*, *The Lesters*, etc., and a valuable book on *Indian Polity* (1868).

CHESS, once known as "checkers," a game played with certain "pieces" on a special "board" described below. It takes its name from the Persian word *shah*, a king, the name of one of the pieces or men used in the game. Chess is the most cosmopolitan of all games, invented in the East (see *History*, below), introduced into the West and now domiciled in every part of the world. As a mere pastime chess is easily learnt, and a very moderate amount of study enables a man to become a fair player, but the higher ranges of chess-skill are attained only by persistent labour. The real proficient or "master" not merely must know the subtle variations in which the game abounds, but must be able to apply his knowledge in the face of the enemy and to call to his aid, as occasion demands, all that he has of foresight, brilliancy and resource, both in attack and in defence. Two chess players fighting over the board may fitly be compared to two famous generals encountering each other on the battlefield, the strategy and the tactics being not dissimilar in spirit.

The Board, Pieces and Moves.—The chess-board is divided (see accompanying diagrams) into 64 chequered squares. In diagram 1 the pieces, or chessmen, are arranged for the beginning of a game, while diagram 2 shows the denomination of the squares according to the English and German systems of notation. Under diagram 1 are the names of the various "pieces"—each side, White or Black, having a King, a Queen, two Rooks (or Castles), two Knights, and two Bishops. The eight men in front are called Pawns. At the beginning of the game the queen always stands upon a square of her own colour. The board is so set that each player has a white square at the right-hand end of the row nearest to him. The rook, knight and bishop nearer to the king are known as King's rook, King's knight, and King's bishop; the other three as Queen's rook, Queen's knight and Queen's bishop.

Briefly described, the powers of the various pieces and of the pawns are as follow:

The king may move in any direction, only one square at a time, except in castling. Two kings can never be on adjacent squares. The queen moves in any direction either diagonally or parallel to the sides of the board, whether forward or backward. There is no limit to her range over vacant squares; an opponent she may take; a piece of her own colour stops her. She is the most powerful piece on the board, for she can move either as a rook or a bishop.

The rooks (from the Indian *ruk* and Persian *rokh*, meaning a soldier or warrior) move parallel to the sides of the board—forward or backward—but they cannot move diagonally. Their range is like the queen's, unlimited, with the same exceptions.

The bishops move diagonally in any direction whether backward or forward. They have an unlimited range, with the same exceptions.

The knights' moves are of an absolutely different kind. They move from one corner of any rectangle of three squares by two to the opposite corner; thus, in diagram 3, the white knight can move to any square occupied by a black one, and vice versa. The move may be made in any direction, e.g., a knight at the square e4 in diagram 2 can move to any one of the eight squares f6, d6, c5, c3, d2, f2, g3, g5. It is no obstacle to the knight's move if intervening squares are occupied. It will be perceived that the knight always moves to a square of a different colour.

The king, queen, rooks and bishops may capture any foeman which stands anywhere within their respective ranges; and the

Queen's Rook (QR); Queen's Knight (QKt); Queen's Bishop (QB); Queen (Q); King (K); King's Bishop (KB); King's Knight (Kkt); King's Rook (KR). The pieces in front of the principal pieces are the pawns (P)

knight can capture the adverse men which stand upon the squares to which they can leap. The piece which takes occupies the square of the piece which is taken, the latter being removed from the board. The king cannot capture any man which is protected by another man.

The moves and capturing powers of the pawns are as follow: Each pawn for its first move may advance either one or two

| | A | B | C | D | E | F | G | H | |

FIG. 2.—SHOWING ENGLISH AND GERMAN SYSTEMS OF NOTATION
The square C.6 is White's Queen's bishop's 6th (QB6) and Black's Queen's bishop's 3rd (QB3). In diagrams it is the convention to show white at the bottom of the board

squares straight forward, but afterwards one square only, and this whether upon starting it exercised its privilege of moving two squares or not. A pawn can never move backwards. It can capture only diagonally—one square to its right or left front. A pawn moves like a rook, captures like a bishop, but only one square at a time. When a pawn arrives at an eighth square, viz., at the extreme limit of the board, it must be exchanged for another piece of the same colour, so that a player may, e.g., have two or more queens on the board at once.

"Check" and "Checkmate." The king can never be captured, but when any piece or pawn attacks him, he is said to be "in check," and the fact of his being so attacked should be announced by the adverse player saying "check," whereupon the king must move from the square he occupies, or be screened from check by the interposition of one of his own men, or the attacking piece must be captured. If, however, when the king is in check, none of these things can be done, it is "checkmate" (Persian, *shah mat*, the king is dead), known generally as "mate," whereupon the game terminates, the player whose king has been thus checkmated being the loser. When the adversary has only his king left it is very easy to checkmate him with only a queen and king, or only a rook and king. The problem is less easy with king and two bishops, and still less easy with king, knight and bishop, in which case the opposing king has to be driven into a corner square whose colour corresponds with the bishop's, mate being given with the bishop. A king and two knights cannot mate, if the opponent play correctly. To mate with king and rook the opposing king must be driven on to one of the four side lines and kept there with the rook on the next line, till it is held by the other king, when the rook mates.

The pawn gives check in the same way as it captures, viz., diagonally. One king cannot give check to another, nor may a king be moved into check.

"Check by discovery" is given when a player, by moving one of his pieces, checks with another of them. "Double check" means

attacking the king at once with two pieces—one of the pieces in this case giving check by discovery.

"Perpetual check" occurs when one player, seeing that he cannot win the game, finds the men so placed that he can give check *ad infinitum*, while his adversary cannot possibly avoid it. The game is then drawn. A game is also drawn "if, before touching a man, the player whose turn it is to play, claim that the game be treated as drawn, and prove that the existing position existed, in the game and at the commencement of his turn of play, twice at least before the present turn."

"Stalemate." When a king is not in check, but his owner has no move left save such as would place the king in check, it is "stalemate," and the game is drawn.

"Castling." This is a special move permitted to the king once only in the game. It is performed in combination with either rook, the king being moved two squares laterally, while the rook towards which he is moved (which must not have previously moved from its square) is placed next him on the other side; the king must be touched first. The king cannot castle after having been once moved, nor when any piece stands between him and the rook, nor if he is in check, nor when he has to cross a square commanded by an adverse piece or pawn, nor into check. It will be perceived that after castling with the king's rook the latter will occupy the KB square, while the king stands on the KKt square, and if with the queen's rook, the latter will occupy the queen's square while the king stands on the QB square.

"Taking *en passant*." This is a privilege possessed by any of the pawns under the following circumstances: If a pawn, say of the white colour, stands upon a fifth square, say upon K5 counting from the white side, and a black pawn moves from Q2 or KB2 to Q4 or KB4 counting from the black side, the white pawn can take the black pawn *en passant*. For the purposes of such capture the latter is dealt with as though it had only moved to Q3 or KB3, and the white pawn taking it diagonally then occupies the square the captured pawn would have reached had it moved but one square. The capture can be made only on the move immediately succeeding that of the pawn to be captured.

"Drawn Game." This arises from a stalemate (noticed above), or from either player not having sufficient force wherewith to effect checkmate, as when there are only two kings left on the board, or king and bishop against king, or king with one knight, or two knights against king, or from perpetual check. One of the players can call upon the other to give checkmate in 50 moves,

the result of failure being that the game is drawn. But, if a pawn is moved, or a piece is captured, the counting must begin again.

A "minor piece" means either a knight or a bishop. "Winning the exchange" signifies capturing a rook in exchange for a minor piece. A "passed pawn" is one that has no adverse pawn either in front or on either of the adjoining files. A "file" is simply a line of squares extending vertically from one end of the board to the other. An "open file" is one on which no piece or pawn of either colour is standing. A

FIG. 3.—DIAGRAM SHOWING THE MOVE OF A KNIGHT. THE WHITE KNIGHT MAY MOVE ON TO ANY OF THE SQUARES OCCUPIED BY THE BLACK KNIGHTS

pawn or piece is *en prise* when one of the enemy's men can capture it. "Gambit" is a word derived from the Ital. *gambetto*, a tripping up of the heels; it is a term used to signify an opening in which a pawn or piece is sacrificed at the opening of a game to obtain an attack. An "opening," or *début*, is a certain set method of commencing the game. When a player can only make one legal move, that move is called a "forced move."

Value of the Pieces.—The relative worth of the chessmen cannot be definitely stated on account of the increase or decrease of their powers according to the position of the game and the pieces, but taking the pawn as the unit the following will be an

estimate near enough for practical purposes: pawn 1, bishop 3.25, knight 3.25, rook 5, queen 9.50. Three minor pieces may more often than not be advantageously exchanged for the queen. Two bishops are usually stronger than two knights, more especially in open positions.

Laws.—The laws of chess differ, although not very materially, in different countries. In competitions among English players the laws adopted are those laid down by the British Chess Federation in 1924.

First Move and Odds.—To decide who moves first, one player conceals a white pawn in one hand and a black pawn in the other, his adversary not seeing in which hand the different pawns are put. The other holds out his hands with the pawns concealed, and his adversary touches one. If that contains the white pawn, he takes the white men and moves first. If he draws the black pawn his adversary has the first move, since white, by convention, always plays first. Subsequently the moves are taken alternately. If one player, by way of odds, "gives" his adversary a pawn or piece, that piece is removed before play begins. If the odds are "pawn and move," or "pawn and two," a black pawn, usually the king's bishop's pawn, is removed and white plays one move, or any two moves in succession but must not pass beyond his fourth rank till his opponent has moved. "Pawn and two" is generally considered to be slightly less in point of odds than to give a knight or a bishop; to give a knight and a bishop is to give rather more than a rook; a rook and bishop less than a queen; two rooks rather more than a queen. The odds of "the marked pawn" can only be given to a much weaker player. A pawn, generally KKt's pawn, is marked with a cap of paper. If the pawn is captured its owner loses the game; he can also lose by being checkmated in the usual way, but he cannot give mate to his adversary with any man except the marked pawn, which may not be moved to an eighth square and exchanged for a piece.

Rules.—If a player touch one of his men he must move it, unless he says *j'adoube* (I adjust), or words of a similar meaning, to the effect that he was only setting it straight on its square. If he cannot legally move a touched piece there is no penalty. He must say *j'adoube* before touching his piece. If a player touch an opponent's piece, he must take it, if he can; if not, make a legal move with the piece by which he made the illegal capture. If he can do neither, no penalty. A move is completed and cannot be taken back as soon as a player, having moved a piece, has taken his hand off it. If a player is called upon to mate under the 50-move rule, "50 moves" means 50 moves and the 49 replies to them. A pawn that reaches an eighth square *must* be exchanged for some other piece of the same colour, the move not being complete until this is done; a second king cannot be selected.

Modes of Notation.—The English and German methods of describing the moves made in a game are different. According to the English method each player counts from his own side of the board, and the moves are denoted by the names of the files and the numbers of the squares. Thus when a player for his first move advances the king's pawn two squares, it is described as follows: "1. P-K4." The following moves, with the aid of diagram 2, will enable the reader to understand the principles of the British notation. The symbol X is used to express "takes"; a dash - to express "to."

- | White. | Black. |
|---|---|
| 1. P-K4 | 1. P-K4 |
| 2. KKt-KB3 (i.e., King's Knight to the third square of the King's Bishop's file) | 2. QKt-QB3 (i.e., Queen's Knight to the third square of the Queen's Bishop's file) |
| 3. KB-QB4 (King's Bishop to the fourth square of the Queen's Bishop's file) | 3. KB-QB4 |
| 4. P-QB3 | 4. KKt-KB3 |
| 5. P-Q4 | 5. P takes P (or PXP) (King's pawn takes White's Queen's pawn) |
| 6. P takes P (or PXP) (Queen's Bishop's pawn takes pawn: no other pawn can, at the moment, capture a pawn) | 6. KB-QKt5 (ch., i.e., check) |

It is now usual to express the notation as concisely as possible; thus, the third moves of White and Black would be given as 3 B-B4, because only the king's bishop and only the queen's bishop's fourth square can be intended.

The French names for the pieces are King, *Roi*; Queen, *Dame*; Rook, *Tour*; Knight, *Cavalier*; Pawn, *Pion*; for Bishop the French substitute *Fou*, a jester. Chess is *Les Échecs*.

The German notation employs the alphabetical characters *a, b, c, d, e, f, g* and *h*, proceeding from left to right, and the numerals 1, 2, 3, 4, 5, 6, 7 and 8, running upwards, these being always calculated from the white side of the board (see diagram 2). Thus the White Queen's Rook's square is *a1*, the White Queen's square is *d1*; the Black Queen's square, *d8*; the White King's square, *e1*; the Black King's square, *e8*, and so with the other pieces and squares. The German names of the pieces are as follows: King, *König*; Queen, *Dame*; Rook, *Turm*; Bishop, *Läufer*; Knight, *Springer*; Pawn, *Bauer*. Chess is *Schach*.

The initials only of the pieces are given, the pawns (*Bauern*) being understood. The Germans use the following signs in their notation, viz.: for "check" (†); "checkmate" (‡); "takes" (:); "castles on king's side" (o-o); "castles on queen's side" (o-o-o); for "best move" a note of admiration (!); for "weak move" a note of interrogation (?). The opening moves just given in the English will now be given in the German notation:

- | White. | Black. |
|------------|-------------|
| 1. e2-e4 | 1. e7-e5 |
| 2. S g1-f3 | 2. S b8-c6 |
| 3. L f1-c4 | 3. L f8-c5 |
| 4. c2-c3 | 4. S g8-f6! |
| 5. d2-d4 | 5. e5-d4: |
| 6. c3-d4: | 6. L c5-b4† |

In both notations the moves are often given in a tabular form, thus:

- | | |
|------------------------|--------------------------|
| 1. $\frac{P-K4}{P-K4}$ | 1. $\frac{e2-e4}{e7-e5}$ |
|------------------------|--------------------------|

White's and below the line Black's.

In the German notation the moves are sometimes still further abbreviated, e.g., the moves given above could also be given thus:

- | White. | Black. |
|--------|---------|
| 1. e4 | 1. e5 |
| 2. Sf3 | 2. Sc6 |
| 3. Lc4 | 3. Lc5 |
| 4. c3 | 4. Sf6! |
| 5. d4 | 5. ed: |
| 6. cd: | 6. Lb4† |

THE OPENINGS

In a short article it is impossible to give even an attempt at an adequate description of the various openings, for on almost every one of them a book might be written. We give below a necessarily very brief *résumé* of the most important openings. For further details the student is recommended to refer to a text-book.

White usually opens with 1. P-K4 or 1. P-Q4. To 1. P-K4, Black has a choice of several replies, those most in favour at the present moment being P-QB4 (the Sicilian Defence), P-K3 (the French Defence) or P-K4. The student, as Black, is recommended to play 1 . . . P-K4 and stand up to whatever attack his opponent may have prepared for him. Fighting on ground chosen by his opponent he will lose games—but gain in experience. After 1. P-K4, P-K4, White has a choice of continuations, viz., 2. P-Q4, 2. P-KB4, 2. Kt-QB3 or 2. Kt-KB3, the last being the most popular. To this move (2. Kt-KB3) Black has several replies, viz., 2 . . . P-Q3 (Philidor's Defence), 2 . . . Kt-KB3 (Petroff's Defence) or 2 . . . Kt-QB3. Philidor's Defence gives Black a cramped game, for his pawn at Q3 obstructs the action of his King's Bishop. Petroff's Defence is quite playable but we recommend the student to play 2 . . . Kt-QB3—and face the music! To that move White has several replies and by defending the various attacks that White can institute Black will learn more than by playing a pet defence with which he is familiar. After 2 . . . Kt-QB3, White can play either 3. P-Q4 (the Scotch

Game), 3. P-B3 (Ponziani's Opening—not to be recommended), 3. B-B4 (the Giuoco Piano—recommended to the student) or 3. B-Kt5 (the Ruy Lopez). To 3. B-B4 Black has two good replies—3... B-B4 or 3... Kt-B3. 3. B-Kt5 is undoubtedly the strongest move for White. The beginner is not, however, recommended to adopt it. The resulting play is full of delicate finesse, having for its object the accumulation of minute advantages, and is not in the bold, attacking, open style that the young player should adopt in order to develop his imagination. The usual defences are 3... P-QR3, 3... Kt-B3 or 3... P-Q3.

1. P-Q4, although very possibly the strongest opening move for White, is *emphatically* not to be recommended to the young player—in fact, we strongly advise him to play chess for several years before experimenting with that opening. The play arising from it is extremely difficult, delicate manoeuvring for slight advantages being the chief theme. It has been described as "classical music." The student adopting this opening at the beginning of his chess career will never go far. The profound character of the play will be entirely beyond his comprehension. He must learn to walk before he can run. After 1. P-Q4, the opening divides into several branches, according to Black's reply. If 1... P-Q4, then 2. P-QB4 to which Black may reply either 2... P×P, 2... P-QB3 or 2... P-K3 (probably best). If 1... Kt-KB3 (much in favour at the moment) then 2. P-QB4 and again Black has a choice of replies. 2... P-K4 is not to be recommended for, after 3. P×P, Kt-Kt5; 4. P-K4, Kt×KP; 5. P-B4, White commands more of the board than his opponent. 2... P-KKt3 is quite playable and leads to a very interesting game. Very popular a few years ago, it is now out of favour, the continuation preferred being 2... P-K3 followed, if 3. Kt-QB3, by 3... B-Kt5 (pinning the Knight and preventing White from obtaining an imposing position in the centre by 4. P-K4), or, if 3. Kt-KB3, by either 3... P-QKt3 or 3... B-Kt5 ch.

Openings less frequently adopted are 1. P-QB4 (the English Opening), 1. Kt-KB3 followed by 2. P-QB4 and later on P-KKt3 (Réti's Opening) and 1. P-KB4 (Bird's Opening). The first two frequently turn by transposition of moves into variations arising from 1. P-Q4. Bird's Opening is not to be recommended for the move 1. P-KB4 weakens the position of White's King. Black has a solid reply in 1... P-Q4 or an attacking one in 1... P-K4, followed, if 2. P×P, by 2... P-Q3; 3. P×P, B×P, giving up the pawn for an advantage in development.

ILLUSTRATIVE GAMES

The following is a selection of noteworthy games played by great masters:

RUY LOPEZ

| White. Capablanca. | Black. Dus- Chotimirski. | White. Capablanca. | Black. Dus- Chotimirski. |
|-----------------------|--------------------------------|-----------------------|--------------------------------|
| 1. P-K4 | P-R4 | 24. R×R | R×R |
| 2. Kt-KB3 | Kt-QB3 | 25. P-K5 (d) | P-Kt3 |
| 3. B-Kt5 | P-QR3 | 26. P-K6 | R-B sq (e) |
| 4. B-R4 | Kt-B3 | 27. Kt-Kt3 | Q-Kt2 (f) |
| 5. Castles | B-K2 | 28. Kt-B5 | P×P (g) |
| 6. R-K sq | P-QKt4 | 29. P×P | Q-B2 (h) |
| 7. B-Kt3 | P-Q3 | 30. Q-B6 | Q-Q sq (i) |
| 8. P-B3 | Kt-QR4 | 31. Kt×B ch | Q×Kt |
| 9. B-B2 | P-B4 | 32. B×QKt P | Kt-B6 |
| 10. P-Q4 | Q-B2 | 33. Q-Q7 | Q×Q |
| 11. QKt-Q2 | Kt-B3 | 34. B×Q | R-Kt sq |
| 12. Kt-B sq | BP×P | 35. P-K7 | K-B2 |
| 13. P×P | Kt-Kt5 | 36. R-K sq | R-K sq |
| 14. P-Q5 | Kt-Q5 | 37. B×R ch | K×B |
| 15. B-Q3 | Castles | 38. R-K6 | P-Q4 |
| | (KR) (a) | 39. K-B sq | Kt-Kt4 |
| 16. B-K3 | QR-B sq | 40. K-K2 | Kt-B2 |
| 17. B×Kt | P×B | 41. R-K5 | Kt-R3 |
| 18. P-QR4 | Q-Kt3 | 42. P-Kt5 | Kt-Kt5 |
| 19. P×P | P×P | 43. P-Kt6 | P-Q6 ch |
| 20. P-R3 | B×Kt (b) | 44. K-Q2 | K-Q2 |
| 21. Q×B | Kt-Q2 | 45. P queens ch | K-Q3 |
| 22. KR-B sq | Kt-B4 | 46. Q-K7 ch | K-B3 |
| 23. P-QKt4 | Kt-R5 (c) | 47. Q×Kt | Resigns (j) |

(b) Up to this point Black has played very well but now he should have played Kt-R4 in order, if possible, to obtain command of his

opponent's KB4, e.g., 15... Kt-R4; 16. B-K3, B×Kt; 17. P×B, Kt-B5; 18. R-B sq, Q-Q2; 19. B×QKt, P×B; 20. Kt-Kt3, P-Kt3, followed by playing his Bishop via B3 to K4. (b) This exchange leaves Black with a weak square at his KB4. (c) If 23... Kt×B, then 24. Q×Kt, followed, if 24... R-B6, by 25. R×R, P×R; 26. R-R5 and the weakness of Black's pawns would have cost him the game. (d) Threatening Q-B5. (e) If 26... P×P, then 27. Q-Kt4. (f) Again, if P×P, then Q-Kt4 with a strong attack. (g) If 28... P×Kt, then 29. Q×P and mate in two more moves. Black's best move was K-R sq, though White, after 29. Q-K4, would have had a great advantage. (h) If 29... Q×Q, then 30. Kt×B ch, winning a piece. (i) Still the Queen cannot be taken. (j) Black might have resigned much earlier. This game was played at St. Petersburg (Leningrad) in 1913.

QUEEN'S PAWN OPENING

| White. Dr. Lasker. | Black. Alekhin. | White. Dr. Lasker. | Black. Alekhin. |
|-----------------------|--------------------|-----------------------|--------------------|
| 1. P-Q4 | P-Q4 | 19. QR-B sq | KR-Q sq |
| 2. P-QB4 | P-K4 (a) | 20. R-B2 | P-B5 |
| 3. QP×P | P-Q5 | 21. P×P | B×P |
| 4. Kt-KB3 | Kt-QB3 | 22. R-Q sq | Kt-B4 |
| 5. P-QR3 | B-Kt5 | 23. B-QB sq | Kt-K6 (g) |
| 6. QKt-Q2 | Q-K2 | 24. R-B5 | Q-B3 (h) |
| 7. P-R3 | B×Kt | 25. Q-K4 (i) | Kt×R (i) |
| 8. Kt×B | Castles | 26. B×B | Kt-B6 (k) |
| 9. Q-Q3 | P-KR3 (b) | 27. B×R | Q×B (l) |
| 10. P-KKt3 | P-KKt3 | 28. Q-K5 | Q-Kt3 |
| 11. B-Kt2 | B-Kt2 | 29. Q-K7 | Q-Q3 |
| 12. Castles | Kt×P | 30. R-K5 | P-Q6 |
| 13. Kt×Kt | B×Kt (c) | 31. P×P | Q×QP |
| 14. P-QKt4 | P-KB4 | 32. R-K3 | Q-Q8 ch (m) |
| 15. P-B5 | Q-K3 (d) | 33. K-R2 | Kt-Kt4 |
| 16. P-B6 | Kt-K2 (e) | 34. R-K6 | Kt×P |
| 17. P×P ch | K-Kt sq | 35. R-KB6 | Resigns (n) |
| 18. B-Kt2 (f) | R-Q3 | | |

(a) A risky move but giving Black chances of counter-attack. Either P-K3 or P-QB3 is safer. (b) If 9... Kt×P, then 10. Q-B5 ch, Kt-Q2; 11. Kt×P, remaining a pawn ahead. (c) Black has certainly regained the pawn sacrificed on his second move but he has the inferior game. White's King's Bishop is very strongly posted, both for attack and defence. (d) If, to stop the further advance of the hostile Queen's Bishop's pawn, Black play P-B3, then P-Kt5, opening up lines of attack on the King. (e) If 16... P×P, then 17. Q-R6 ch. (f) Preferable would have been B-Q2, to guard against the possibility of the further advance of Black's King's Bishop's pawn. (g) Very clever for, if 24. P×Kt, then 24... P×P and Black wins. (h) If 24... Kt×R, then 25. B×B and Black has two pieces *en prise*. (i) Having removed his Queen from the line of action of the hostile Rooks, White now threatens P×Kt. (j) It would have been better to play Kt×B. (k) Better would have been R (Q3)-Q2 but White's pieces were so well posted that he would still have had the better game. (l) White's last move was extraordinarily fine. If now 27... Kt×Q, then 28. B×P ch, K×P; 29. B×Kt ch, K-B sq (if 29... K-R3, then 30. R-R5 mate); 30. B-K5 ch, regaining the Queen and winning easily. If (instead of 27... Kt×Q) Black play 27... P×B, then 28. R-B8 ch, R×R; 29. P×R=Q ch, K×Q; 30. Q-R8 ch, followed by 31. Q×P, and White has a winning advantage. (m) If 32... Q-Q5 or Q7, then 33. R×Kt. (n) For he has no reply to the threatened R-B8. This game was played in the great St. Petersburg tournament of 1914. Dr. Lasker was at that time champion of the world.

QUEEN'S PAWN OPENING

| White. Alekhin. | Black. Kussmann. | White. Alekhin. | Black. Kussmann. |
|--------------------|---------------------|--------------------|---------------------|
| 1. P-Q4 | P-Q4 | 11. B×B ch | Kt×B |
| 2. Kt-KB3 | Kt-KB3 | 12. Castles | P×P (b) |
| 3. P-B4 | P-K3 | 13. Kt×P | R-Q sq (c) |
| 4. Kt-B3 | P-B4 | 14. Kt-KB5 | Kt-K4 |
| 5. B×P | KP×P | 15. Q-K2 | P-Kt3 |
| 6. B-Kt5 | B-K3 (a) | 16. Q-Kt5 ch | Kt-Q2 (d) |
| 7. B×Kt | Q×B | 17. KR-B sq (e) | B-Kt5 (f) |
| 8. P-K4 | QP×P | 18. Kt-B6 ch | K-B sq |
| 9. B-Kt5 ch | B-Q2 | 19. Kt×Kt ch | R×Kt |
| 10. Kt×P | Q-QKt3 | 20. Q-K5 (g) | Resigns |

(a) A mistake. B-K2, unpinning the Knight, should have been played. Now White obtains an advantage in development. (b) This again furthers White's development. B-K2 should have been played, preparatory to Castles (KR). (c) If now 13... B-K2, then 14. Kt-KB5. (d) If 16... Q×Q, then 17. Kt-B6 mate. (e) Threatening Kt(K4)-Q6 or B6 mate. (f) If 17... P×Kt, then 18. Kt-Q6 mate, or, if 17... B-K2, then 18. Kt (K4)-Q6 ch, K-B sq; 19. R×B, Q×Q; 20. R×P ch, K-Kt sq; 21. Kt-R6 or K7 mate. (g) Threatening either Q×R mate, Q-K8 mate or Q-Kt7 mate. No

wonder that Black resigned! This game was one of eighteen played simultaneously by Alekhin in the Newspaper Club at New York in 1924.

FRENCH DEFENCE

| White. Bogoljubow. | Black. Réti. | White. Bogoljubow. | Black. Réti. |
|-----------------------|-----------------|-----------------------|-----------------|
| 1. P-K4 | P-K3 | 23. R-B2 (f) | Kt-K6 |
| 2. P-Q4 | P-Q4 | 24. R-K sq | P-B5 |
| 3. Kt-QB3 | Kt-KB3 | 25. P-QKt4 | B-R5 |
| 4. P-K5 | KKt-Q2 | 26. R(K sq)-K2 | Kt-Q8 |
| 5. Q-Kt4 | P-QB4 | 27. R-B sq | Kt-B6 |
| 6. Kt-Kt5 | PXP | 28. R(K2)-B2 | Kt-Kt8 |
| 7. Kt-KB3 (a) | Kt-QB3 | 29. B-Kt2 | P-B6 |
| 8. Kt-Q6 ch (b) | BXKt | 30. Kt-Kt3 (g) | BXKt |
| 9. QXKtP | BXP | 31. RPXB | Kt-Q7 |
| 10. KtXB | Q-B3 | 32. R-K sq | KR-Q sq |
| 11. QXQ | KtXQ | 33. B-B sq | P-Q6 |
| 12. B-QKt5 | B-Q2 | 34. PXP (h) | RXP |
| 13. Kt-B3 | Kt-K5 | 35. BXKt | RXB |
| 14. Castles | P-B3 (c) | 36. R-R sq | K-K3 |
| 15. KtXP | P-QB4 (d) | 37. K-B sq | RXR ch |
| 16. Kt-K2 | K-B2 | 38. KXR | P-B7 |
| 17. P-KB3 | Kt-Q3 | 39. R-QB sq | K-Q4 |
| 18. P-QKt3 | P-K4 | 40. K-K3 | R-B6 ch |
| 19. B-R3 | QR-QB sq | 41. K-Q2 | K-Q5 |
| 20. QR-Q sq | P-Q5 | 42. P-R4 | R-Q6 ch (i) |
| 21. Kt-B sq | Kt-B4 (e) | Resigns | |

(a) Not 7. Kt-Q6 ch, B×Kt; 8. Q×Kt P because of 8... B×P and Black wins. (b) A premature attack which leaves White at a great disadvantage. (c) Threatening to maintain his extra pawn by P-K4. (d) White has recovered his pawn but Black has an overwhelming advantage in position on account of his tremendously strong centre of pawns. It will be seen that White, although he struggles on for another thirty moves, is all the time fighting a losing battle. (e) The Knight now starts on a remarkable tour. (f) Slightly better would have been KR-K sq, as then the Knight could not immediately go to K6 because of the reply R×Kt. (g) If 30. B-R sq, then 30... Kt-Q7 followed by B×P. (h) If 31. B×Kt, then 31... P×B; 32. R×QP, P×P; 33. R×R, R×R (threatening R-Q8) and White is helpless. (i) The simplest way—for, if 43 K×P, then 43... R-B6 ch; 44. K-Q2, R×R; 45. K×R, K-K6 and Black's King eats up the King's side pawns. If 43 K-K2, then 43... K-B6, threatening K-Kt7. This very instructive game was played in the Mährisch-Ostrau tournament (1923).

QUEEN'S PAWN OPENING

| White. Dr. Tarrasch. | Black. Dr. Tartakower. | White. Dr. Tarrasch. | Black. Dr. Tartakower. |
|-------------------------|---------------------------|-------------------------|---------------------------|
| 1. P-Q4 | P-Q4 | 22. KtXQBP | RXKt |

| 13. B-K4 | KKtXP | 34. P-B7 | B-B4 (g) |
| 14. KtXKt | QXKt | 35. P queens ch | BXQ |
| 15. Kt-B3 | Q-QB4 | 36. Q-B7 | R-Q Kt4 |
| 16. B-B4 (b) | B-Q3 | 37. QXB ch | KXP |
| 17. B×Kt | PXB | 38. P-QR4 | R-QB4 |
| 18. BXB | RXB | 39. Q-Kt4 | QXR |
| 19. Kt-K5 | KR-Q sq | 40. R×Q | R-B8 ch |
| 20. Q-R4 | P-Q6 | 41. Q-Q sq | Resigns (h) |
| 21. P-QKt4 | Q-Q5 | | |

(a) Setting a trap. If now 7... KtXP, then 8. Q-K2 (not 8. KtXKt because of 8... Q-R4 ch), P-B3; 9. KtXKt, Q-R4 ch; 10. K-Q sq, P×Kt; 11. R-K sq, winning the King's pawn for, if 11... B-Q3 then 12. P-B4. (b) A very beautiful move for, if now 16... B×BP, then 17. Q×B, Q×Q; 18. B-B5 ch, R-Q2; 19. R-K8 ch, Kt-Q sq; 20. Kt-K5 and White wins. (c) If instead of 18... R-Q2 Black play 18... Q-K3, then 19. R×Q, P×R; 20. B×P ch, R-Q2; 21. Kt-K5, KtXKt; 22. B×Kt followed by B×R ch and the capture of the Queen's pawn. (d) If 28... K-B sq, then 29. P-B6, threatening mate and so winning the Bishop, or, if 28... K-R sq, then 29. P-B6, B-B sq; 30. P-B7 and White wins. (e) White's final attack is well worth very careful study. (f) If 31...

P×P, then 32. Q×P ch, K-B sq (32... K-R sq; 33. Q-R6 ch gives the same result); 33. Q-B6 ch, K-Kt sq; 34. either R-Kt sq ch and mate in a few moves. If (instead of 31... P×P) Black play 31... Q-Q2, then 32. R×P and wins. (g) If 32... R×P, then 33. Q×P and wins. (h) If 34... R×Q, then 35. P queens ch, K×P; 36. Q×B. (i) This game, from the Berlin tournament (1920), is one of the prettiest ever played.

QUEEN'S PAWN OPENING

| White. Gilg. | Black. Niemzowitsch. | White. Gilg. | Black. Niemzowitsch. |
|-----------------|-------------------------|------------------|-------------------------|
| 1. P-Q4 | P-KB4 (a) | 14. PXP | Q-R4 |
| 2. P-KKt3 | P-Q3 | 15. Kt-B sq | B-QB4 (e) |
| 3. B-Kt2 | Kt-KB3 | 16. B-K3 | BXB |
| 4. P-QB3 (b) | Kt-B3 | 17. KtXB | B-Q2 |
| 5. Kt-KR3 | P-K4 | 18. Q-Q4 | QR-K sq (f) |
| 6. Castles | P-KR3 (c) | 19. Kt-B sq (g) | P-KKt4 |
| 7. P-B3 | P-Q4 | 20. Kt-Kt sq | Kt-K5 (h) |
| 8. K-R sq | B-Q3 | 21. Kt-R3 (i) | Kt(Kt5)-B3 |
| 9. PXP | KtXP | 22. B×Kt (j) | KtXB |
| 10. Kt-Q2 (d) | Castles | 23. Kt-Kt sq (k) | Kt-B7 ch |
| 11. P-K4 | BPXP | 24. K-Kt2 | B-R6 ch |
| 12. PXP | QKt-Kt5 | Resigns (l) | |
| 13. R-K sq | Q-K sq | | |

(a) The Dutch defence. It is risky but gives chances of counter-attack. (b) Unnecessary, as the Queen's pawn was not attacked. Better would have been Kt-QB3 in order to play P-K4. (c) Leaving the hostile King's Knight without a move. (d) If 10. P-KB4, then 10... Kt-B2; 11. B×P, KtXB; 12. Q×Kt, Castles, and White, although a Pawn ahead, has a bad game as his King's position is weak and he has no good posts at which to place his pieces. (e) Threatening Q×Kt, e.g., 16... Q×Kt; 17. B×Q, Kt-B7 ch; 18. K-Kt sq (if 18. K-Kt2, then 18... B×B ch), KtXQ ch, and wins. (f) 18... KtXKt looks tempting as White's Knight at R3 is then twice attacked. White, however, before recapturing at K3, plays Kt-B4, attacking the Queen. (g) A mistake. White should have endeavoured to break the hostile attack by exchanging pieces. The correct continuation was 19. KtXKt, KtXKt; 20. K-Kt sq. (h) Very neat, threatening 21... either Kt-B7 ch; 22. Q×Kt, KtXQ mate. (i) If, instead, 21. R-K2, Black wins by a pretty sacrifice of his Queen, e.g., 21... Q×P ch; 22. KtXQ, KtXP mate. (j) If, instead, White, to save his Knight at R3 (which is attacked) play 22. Kt-Kt sq, then 22... Kt-B7 ch; 23. Q×Kt, Kt-Kt5; 24. Q-Q4, Kt-B7 ch, winning the Queen. (k) If 23. R×Kt, then 23... Q-B6 ch. (l) For, if 25. KtXB, then 25... Q-B6 ch; 26. K-Kt sq, Q-R8 mate. Played in the Semmering tournament (1926).

FALKBEER COUNTER-GAMBIT

| White. Spielmann. | Black. Dr. Tarrasch. | White. Spielmann. | Black. Dr. Tarrasch. |
|----------------------|-------------------------|----------------------|-------------------------|
| 1. P-K4 | P-K4 | 15. KtXB | KtXKt |
| 2. P-KB4 | P-Q4 (a) | 16. PXP | Q-R5 ch |
| 3. KPXP | P-K5 | 17. K-B sq (g) | R-KB sq |
| 4. P-Q3 | Kt-KB3 | 18. K-Kt sq | Q-Q5 ch |
| 5. PXP | KtXKP | 19. B-K3 (h) | QXKP |
| 6. Kt-KB3 | B-QB4 | 20. R-K sq | Kt-Q2 |
| 7. Q-K2 | B-B4 (b) | 21. Q-B4 | Kt-R sq |
| 8. P-KKt4 (c) | Castles (d) | 22. B-K4 | QR-K sq |
| 9. PXP | R-K sq | 23. B-Q4 | Q-B5 |
| 10. B-Kt2 (e) | Kt-B7 | 24. R-K2 | Kt-B3 |
| 11. Kt-K5 | KtXR | 25. B×Kt | PXB |
| 12. B×Kt | Kt-Q2 (f) | 26. P-KR3 | R-Kt sq ch |
| 13. Kt-QB3 | P-KB3 | Resigns (i) | |
| 14. Kt-K4 | PXKt | | |

(a) White's last move has slightly weakened his King's side and Black immediately attacks. (b) B-B7 ch is disadvantageous to Black, e.g., 7... B-B7 ch; 8. K-Q sq, Q×P ch; 9. KKt-Q2, P-KB4; 10. Kt-B3, Q-Q5; 11. KtXKt, P×Kt; 12. P-B3, Q-K6; 13. Q-R5 ch, and White has the attack. (c) This move was for many years considered to refute Black's last move until Dr. Tarrasch succeeded in this game in upsetting that opinion. (d) This is Dr. Tarrasch's ingenious innovation. He gives up a piece for an overwhelming attack. (e) If 10. Kt-K5, then 10... Q-R5 ch, or, if 10. Q-Kt2, then 10... Q×P; 11. B-K2, Kt-QB3; 12. Kt-B3, Q×BP and Black has a fine game. (f) Not P-KB3 at once, e.g., 12... P-KB3; 13. P-Q6, PXP (if 13... P×Kt, then 14. Q-B4 ch, followed by Q×B); 14. B-Q5 ch, K-B sq; 15. Q-R5. (g) If 17. K-Q sq, then 17... Q-Q5 ch, followed by Q×KP. (h) If 19. Q-K3, then 19... Q-Q8 ch. (i) For, if 27. K-R sq, then 27... Q-KB8 ch; if 27. B-Kt2, then 27... R×R; or, if 27. R-Kt2, then 27... R×R ch; 28. K×R, Q×B ch. For this game, played in the Mährisch-Ostrau tournament (1923), Dr. Tarrasch was awarded a brilliancy prize. Apart from its brilliancy, it is of great value theoretically.

End Games.—A game of chess consists of three branches—the opening, the middle and the end game. The *openings* have been analysed and are to be acquired by the study of the books on the subject. The *middle game* can only be acquired practically. The combinations being inexhaustible in their variety, individual ingenuity has its full scope. Those endowed with a fertile imagination will evolve plans and combinations leading to favourable issues. The less endowed player, however, is not left quite defenceless; he has necessarily to adopt a different system, namely, to try to find a weak point in the arrangement of his opponent's forces and concentrate his attack on that weak spot. As a matter of fact, in a contest between players of equal strength, finding the weak point in the opponent's armour is the only possible plan, and this may be said to be the fundamental principle of the modern school. In the good old days the battles were mostly fought in the neighbourhood of the king, each side striving for a checkmate. Nowadays the battle may be fought anywhere. It is quite immaterial where the advantage is gained, be it ever so slight. Correct continuation will necessarily increase it, and the opponent may be compelled to surrender in the end game without being checkmated, or a position may be reached when the enemies, in consequence of the prolonged fight, are so reduced that the kings themselves have to take the field—the *end game*. The *end game*, therefore, requires a special study. It has its special laws and the value of the pieces undergoes a considerable change. The kings leave their passive rôle and become attacking forces. The pawns increase in value, whilst that of the pieces may diminish in certain cases. Two knights, for instance, without pawns, become valueless, as no checkmate can be effected with them, if the opponent play correctly. In the majority of cases the players must be guided by general principles, as the standard examples do not meet all cases.

HISTORY OF CHESS

The origin of chess is lost in obscurity. Its invention has been variously ascribed to the Greeks, Romans, Babylonians, Scythians, Egyptians, Jews, Persians, Chinese, Hindus, Arabians, Araucanians, Castilians, Irish and Welsh. Some have endeavoured to fix upon particular individuals as the originators of the game; amongst others upon Japheth, Shem, King Solomon, the wife of Ravan, king of Ceylon, the philosopher Xerxes, the Greek chieftain Palamedes, Hermes, Aristotle, the brothers Lydo and Tyrrhene, Semiramis, Zenobia, Attalus (d. c. 200 B.C.), the mandarin Hansing, the Brahman Sissa and Shatrensch, stated to be a celebrated Persian astronomer. Many of these ascriptions are fabulous, others rest upon little authority, and some of them proceed from easily traceable errors, as where the Roman games of *Ludus Latrunculorum* and *Ludus Calculorum*, the Welsh recreation of *Tawlbwrdd* (throw-board) and the ancient Irish pastime of *Fithcheall* are assumed to be identical with chess; so far as the Romans and Welsh are concerned, the contrary can be proved, while from what little is known of the Irish game it appears not to have been a sedentary game at all. Mr. N. Bland, M.R.A.S., in his *Persian Chess* (London, 1850), endeavoured to prove that the Persians were the inventors of chess, and maintained that the game, born in Persia, found a home in India, whence after a series of ages it was brought back to its birthplace. The view, however, which has obtained the most credence, is that which attributes the origin of chess to the Hindus. Dr. Thomas Hyde of Oxford, writing in 1694 (*De Ludis Orientalibus*), seems to have been the first to propound this theory, but he appears to have been ignorant of the game itself, and the Sanskrit records were not accessible in his time. About 1783–89 Sir William Jones, in an essay published in the 2nd vol. of *Asiatic Researches*, argued that Hindustan was the cradle of chess, the game having been known there from time immemorial by the name of *chaturanga*, that is, the four *angas*, or members of an army, which are said in the *Amarakosha* to be elephants, horses, chariots and foot-soldiers. As applicable to real armies, the term *chaturanga* is frequently used by the epic poets of India. Sir William Jones's essay is substantially a translation of the *Bhāṣya Purāṇa*, in which is given a description of a four-handed game of chess

played with dice. A pundit named Rhadhakant informed him that this was mentioned in the oldest law books, and also that it was invented by the wife of Ravan, king of Lanka (Ceylon), in the second age of the world in order to amuse that monarch while Rama was besieging his metropolis. This account claims for chess an existence of 4,000 or 5,000 years. Sir William, however, grounds his opinions as to the Hindu origin of chess upon the testimony of the Persians and not upon the above manuscript, while he considers the game described therein to be more modern than the Persian game. Though sure that the latter came from India and was invented there, he admits that he could not find any account of it in the classical writings of the Brahmans. He lays it down that chess, under the Sanskrit name *chaturanga*, was exported from India into Persia in the 6th century of our era; that by a natural corruption the old Persians changed the name into *chatrang*, but when their country was soon afterwards taken possession of by the Arabs, who had neither the initial nor final letter of the word in their alphabet, they altered it further into *shatranj*, which name found its way presently into modern Persian and ultimately into the dialects of India.

Van der Linde, in his exhaustive work, *Geschichte und Literatur des Schachspiels* (1874), has much to say of the origin-theories, nearly all of which he treats as so many myths. He agrees with those who consider that the Persians received the game from the Hindus. The outcome of his studies appears to be that chess certainly existed in Hindustan in the 8th century, and that probably that country is the land of its birth. He inclines to the idea that the game originated among the Buddhists, whose religion was prevalent in India from the 3rd to the 9th century. According to their ideas, war and the slaying of one's fellow-men, for any purposes whatever, is criminal, and the punishment of the warrior in the next world will be much worse than that of the simple murderer; hence chess was invented as a substitute for war. Van der Linde is in agreement with Sir William Jones in taking the view that the four-handed game of the original manuscript is a comparatively modern adaptation of the Hindu chess, and he altogether denies that there is any proof that any form of the game has the antiquity attributed to it.

H. J. R. Murray, in his monumental work *A History of Chess* (see bibliography), comes to the conclusion that chess is a descendant of an Indian game played in the 7th century.

Altogether, therefore, we find the best authorities agreeing that chess existed in India before it is known to have been played anywhere else. In this supposition they are strengthened by the names of the game and of some of the pieces. *Shatranj*, as Forbes has pointed out, is a foreign word among the Persians and Arabians, whereas its natural derivation from the term *chaturanga* is obvious. Again *al-fil*, the Arabic name of the bishop, means the elephant, otherwise *alephhind*, the Indian ox. Our earliest authority on chess is Masudi, an Arabic author who wrote about A.D. 950. According to him, *shatranj* had existed long before his time; and though he may speak not only for his own generation but for a couple of centuries before, that will give to chess an existence of over 1,000 years.

Early and Mediaeval Times.—The dimness which shrouds the origin of chess naturally obscures also its early history. We have seen that chess crossed over from India into Persia, and became known in the latter country by the name of *shatranj*. Some have understood that word to mean "the play of the king"; but undoubtedly Sir William Jones's derivation carries with it the most plausibility. How and when the game was introduced into Persia we have no means of knowing. The Persian poet Firdousi, in his historical poem, the *Shāhnāma*, gives an account of the introduction of *shatranj* into Persia in the reign of Chosroes I. Anushirwan, to whom came ambassadors from the sovereign of Hind (India), with a chess-board and men asking him to solve the secrets of the game, if he could, or pay tribute. The king asked for seven days' grace, during which time the wise men vainly tried to discover the secret. Finally, the king's minister took the pieces home and discovered the secret in a day and a night. He then journeyed to India with a game of his own invention, *nard*, which the Indians were unable to reconstruct.

Other Persian and Arabian writers state that *shatranj* came into Persia from India and there appears to be a consensus of opinion that may be considered to settle the question. Thus we have the game passing from the Hindus to the Persians and thence to the Arabians, after the capture of Persia by the caliphs in the 7th century, and from them, directly or indirectly, to various parts of Europe, at a time which cannot be definitely fixed, but either in or before the 10th century. That the source of the European game is Arabic is clear enough, not merely from the words "check" and "mate," which are evidently from *Shah mat* ("the king is dead"), but also from the names of some of the pieces. There are various chess legends having reference to the 7th and 8th centuries, but these may be neglected as historically useless; and equally useless appear the many oriental and occidental romances which revolve around those two great central figures, Harun al-Rashid and Charlemagne. There is no proof that either of them knew anything of chess or, so far as the latter is concerned, that it had been introduced into Europe in his time. True, there is an account given in Gustavus Selenus, taken from various old chronicles, as to the son of Prince Okar or Otkar of Bavaria having been killed by a blow on the temple, struck by a son of Pippin after a game of chess; and there is another well-known tradition as to the magnificent chess-board and set of men said to have been sent over as a present by the empress Irene to Charlemagne. But both tales are not less mythical than the romance which relates how the great Frankish monarch lost his kingdom over a game of chess to Guérin de Montglave; for van der Linde shows that there was no Bavarian prince of the name of Okar or Otkar at the period alluded to, and as ruthlessly shatters the tradition about Irene's chess-men. With respect to Harun al-Rashid, among the various stories told which connect him with chess there is one that at first sight may seem entitled to some degree of credit. In the annals of the Moslems by Abulfeda (Abu'l Fida) there is given a copy of a letter stated to be "From Nicephorus, emperor of the Romans, to Harun, sovereign of the Arabs," which (using Professor Forbes's translation), after the usual compliments, runs thus: "The empress (Irene) into whose place I have succeeded, looked upon you as a *Rukh* and herself as a mere Pawn; therefore she submitted to pay you a tribute more than the double of which she ought to have exacted from you. All this has been owing to female weakness and timidity. Now, however, I insist that you, immediately on reading this letter, repay to me all the sums of money you ever received from her. If you hesitate, the sword shall settle our accounts." Harun's reply, written on the back of the Byzantine emperor's letter, was terse and to the point. "In the name of God the merciful and gracious. From Harun, the commander of the faithful, to the Roman dog Nicephorus. I have read thine epistle, thou son of an infidel mother; my answer to it thou shalt see, not hear." Harun was as good as his word, for he marched immediately as far as Heraclea, devastating the Roman territories with fire and sword, and soon compelled Nicephorus to sue for peace. Now the points which give authority to this narrative and the alleged correspondence are that the relations which they assume between Irene and Nicephorus on the one hand and the warlike caliph on the other are confirmed by the history of those times, while, also, the straightforward brevity of Harun's reply commends itself as what one might expect from his soldier-like character. Still, the fact must be remembered that Abulfeda lived about five centuries after the time to which he refers. Perhaps we may assume that it is not improbable that the correspondence is genuine; but that the words *ruk* and *pawn* may have been substituted for other terms of comparison originally used.

As to how chess was introduced into western and central Europe nothing is really known. The Spaniards very likely received it from their Moslem conquerors, the Italians not improbably from the Byzantines, and in either case it would pass northwards to France, going on thence to Scandinavia and England. Some say that chess was introduced into Europe at the time of the Crusades, the theory being that the Christian warriors learned to play it at Constantinople. This is negated by a curious epistle of St. Peter Damian, cardinal bishop of Ostia, to Pope Alexander

II. written about A.D. 1061, which, assuming its authenticity, shows that chess was known in Italy before the date of the first crusade. The cardinal, as it seems, had imposed a penance upon a bishop whom he had found diverting himself at chess; and in his letter to the pope he repeats the language he had held to the erring prelate, viz., "Was it right, I say, and consistent with thy duty, to sport away thy evenings amidst the vanity of chess, and defile the hand which offers up the body of the Lord, and the tongue that mediates between God and man, with the pollution of a sacrilegious game?" Among those who took an unfavourable view of the game may be mentioned John Huss, who, when in prison, deplored his having played at chess, whereby he had lost time and run the risk of being subject to violent passions. Among authentic records of the game may be quoted the *Alexiad* of the princess Anna Comnena, in which she relates how her father, the emperor Alexius, used to divert his mind from the cares of State by playing at chess with his relatives. This emperor died in 1118.

Concerning chess in England there is the usual confusion between legend and truth. Snorre Sturleson relates that as Canute was playing at chess with Earl Ulf, a quarrel arose, which resulted in the upsetting of the board by the latter, with the further consequence of his being murdered in church a few days afterwards by Canute's orders. Carlyle, in *The Early Kings of Norway*, repeats this tale, but van der Linde treats it as a myth. The *Ramsey Chronicle* relates how Bishop Utheric, coming to Canute at night upon urgent business, found the monarch and his courtiers amusing themselves at dice and chess. There is nothing intrinsically improbable in this last narrative; but Canute died about 1035, and the date, therefore, is suspiciously early. Moreover, allowance must be made for the ease with which chroniclers described other games as chess.

As regards the individual pieces, the king seems to have had the same move as at present; but it is said he could formerly be captured. His "castling" privilege is a European invention; but he formerly leaped two and even three squares, and also to his Kt2. Castling dates no farther back than the first half of the 16th century. The queen has suffered curious changes in name, sex and power. In *shatranj* the piece was called *farz* or *firz* (also *farzan*, *farzin* and *farzi*), signifying a "counsellor," "minister" or "general." This was latinized into *farzia* or *fercia*. The French slightly altered the latter form into *fierce*, *fiere*, and, as some say, *vierge*, which, if true, might explain its becoming a female. Another and much more probable account has it that whereas formerly a pawn on reaching an eighth square became a *farzin*, and not any other piece, which promotion was of the same kind as at draughts (in French, *dames*), so she became a *dame* or queen as in the latter game, and thence *dama*, *donna*, etc. There are old Latin manuscripts in which the terms *ferzia* and *regina* are used indifferently. The queen formerly moved only one square diagonally and was consequently the weakest piece on the board. The immense power she now possesses seems to have been conferred upon her so late as about the middle of the 15th century. It will be noticed that under the old system the queens could never meet each other, for they operated on diagonals of different colours. The bishop's scope of action was also very limited formerly; he could only move two squares diagonally, and had no power over the intermediate square, which he could leap over whether it was occupied or not. This limitation of their powers prevailed in Europe until the 15th century. This piece, according to Forbes, was called among the Persians *pil*, an elephant, but the Arabs, not having the letter *p* in their alphabet, wrote it *fil*, or with their definite article *al-fil*, whence *alphilus*, *alfinus*, *alfiere*, the latter being the word used by the Italians; while the French perhaps get their *fol* and *fou* from the same source. The pawns formerly could move only one square at starting; their powers in this respect were increased about the early part of the 16th century. It was customary for them on arriving at an eighth square to be exchanged only for a *farzin* (queen), and not any other piece; the rooks (so called from the Indian *ruk* and Persian *rokh*, meaning "a soldier") and the knights appear to have always had the same powers as at present. As to the chess-boards, they were formerly uncoloured, and it is not until the

13th century that we hear of chequered boards being used in Europe.

Development in Play.—The change of *shatranj* into modern chess took place most probably first in France, and thence made its way into Spain early in the 15th century, where the new game was called *Axedrez de la dama*, being also adopted by the Italians under the name of *scacci alla rabiosa*. The time of the first important writer on modern chess, the Spaniard Ruy Lopez de Segura (1561), is also the period when the latest improvement, castling, was introduced, for his book (*Libro de la invencion liberal y arte del juego del Axedrez*), though treating of it as already in use, also gives the old mode of play, which allowed the king a leap of two or three squares. Shortly afterwards the old *shatranj* disappears altogether. Lopez was the first who merits the name of chess analyst. At this time flourished the flower of the Spanish and Italian schools of chess—the former represented by Lopez, Ceron, Santa Maria, Busnardo and Avalos; the latter by Giovanni Leonardo da Cutri (il Puttino) and Paolo Boi (il Syracuseano). In the years 1562–75 both Italian masters visited Spain and defeated their Spanish antagonists. During the whole 17th century we find but one worthy to be mentioned, Giacchino Greco (il Calabrese). The middle of the 18th century inaugurates a new era in chess. The leading man of this time was François André Danican Philidor. He was born in 1726 and was trained by M. de Kermar, Sire de Légal, the star of the *Café de la Régence* in Paris, which was the centre of French chess until early in the 20th century. In 1747 Philidor visited England, and defeated the Arabian player, Phillip Stamma, by eight games to one and one draw. In 1749 he published his *Analyse des échecs*, a book which went through more editions and was more translated than any other work upon the game. During more than half a century Philidor travelled much, but never went to Italy, the only country where he could have found opponents of first-rate skill. Italy was represented in Philidor's time by Ercole del Rio, Lolli and Ponziani. Their style was less sound than that of Philidor, but certainly a much finer and in principle a better one. As an analyst the Frenchman was in many points refuted by Ercole del Rio ("the anonymous Modenese"). Blindfold chess-play, already exhibited in the 11th century by Arabian and Persian experts, was taken up afresh by Philidor, who played on many occasions three games simultaneously without sight of board or men. These exhibitions were given in London, at the Chess club in St. James's street, and Philidor died in that city in 1795. As eminent players of this period must be mentioned Count Ph. J. van Zuylen van Nyevelt (1743–1826), and the German player J. Allgaier (1763–1823), after whom a well-known brilliant variation of the King's Gambit is named. Philidor was succeeded by Alexandre Louis Honoré Lebreton Deschappelles (1780–1847), who was also a famous whist player. The only player who is known to have fought Deschappelles not unsuccessfully on even terms is John Cochrane. He also lost a match (1821) to W. Lewis, to whom he conceded the odds of "pawn and move," the Englishman winning one and drawing the two others. Deschappelles' greatest pupil, and the strongest player France ever possessed, was Louis Charles Mahé de la Bourdonnais, who was born in 1797 and died in 1840. His most memorable achievement was his contest with the English champion, Alexander Macdonnell, the French player winning in the proportion of three to two.

The English school of chess began about the beginning of the 19th century, and Sarratt was its first leader. He flourished from 1808 to 1821, and was followed by his great pupil, W. Lewis, who will be principally remembered for his writings. His literary career belongs to the period from 1818 to 1848 and he died in 1869. A. Macdonnell (1798–1835) has been already mentioned. To the same period belong also Captain Evans, the inventor of the celebrated "Evans Gambit" (1828), who died at a very advanced age in 1873; Perigal, who participated in the correspondence matches against Edinburgh and Paris; George Walker, for 30 years chess editor of *Bell's Life in London*; and John Cochrane, who met every strong player from Deschappelles downwards. In the same period Germany possessed but one good player, J. Mendheim of Berlin. The fifth decade of the 19th century is marked

by the fact that the leadership passed from the French school to the English. After the death of la Bourdonnais, Fournié de Saint-Amant became the leading player in France; he visited England in the early part of 1843, and successfully met the best English players, including Howard Staunton (q.v.); but the latter soon took his revenge, for in Nov. and Dec. 1843 a great match between Staunton and Saint-Amant took place in Paris, the English champion winning by 11 games to six with four draws. During the succeeding eight years Staunton maintained his reputation by defeating Popert, Horwitz and Harrwitz. Staunton was defeated by Anderssen at the London tournament in 1851, and this concluded his match-playing career.

In the ten years 1830–40 a new school arose in Berlin, the seven leaders of which have been called "The Pleiades." These were Bledow (1795–1846), Bilguer (1815–1840), Hanstein (1810–1850), Mayet (1810–1868), Schorn (1802–1850), B. Horwitz (b. 1809) and von Heydebrand und der Lasa, once German ambassador at Copenhagen. As belonging to the same period must be mentioned the three Hungarian players, Grimm, Szen and J. Löwenthal.

Among the great masters since the middle of the 19th century Paul Morphy (1837–1884), an American, has seldom been surpassed as a chess player. His career was short but brilliant. Born in New Orleans in 1837, he was taught chess by his father when only ten years of age, and in two years' time became a strong player. When not quite 13 he played three games with Löwenthal and won two of them, the other being drawn. He was 20 years of age when he competed in the New York congress of 1857, where he won the first prize. In 1858 he visited England, and there defeated Boden, Medley, Mongredien, Owen, Bird and others. He also beat Löwenthal by nine games to three and two draws. In the same year he played a match at Paris with Harrwitz, winning by five to two and one drawn; and later on he obtained a victory over Anderssen. On two or three occasions he played blindfold against eight strong players simultaneously, each time with great success. He returned to America in 1859 and continued to play, but with decreasing interest in the game, until 1866. He died in 1884.

Wilhelm Steinitz (b. 1836) took the sixth prize at the London congress of 1862. He defeated Blackburne in a match by seven to one and two draws. In 1866 he beat Anderssen in a match by eight games to six. In 1868 he carried off the first prize in the British Chess Association handicap, and in 1872 in the London grand tourney, also defeating Zukertort in a match by seven games to one and four draws. In 1873 he carried off the first prize at the Vienna congress; and in 1876 he defeated Blackburne, winning seven games right off. In 1872–74, in conjunction with W. N. Potter, he conducted and won a telegraphic correspondence match for London against Vienna. In Philidor's age it was considered almost incredible that he should be able to play three simultaneous games without seeing board or men, but Paulsen, Blackburne and Zukertort often played ten or 12 such games, while as many as 28 and 29 were so played by Alekhin and Réti, respectively, in 1925.

In 1876 England was in the van of the world's chess army. English-born players then were Boden, Burn, Macdonnell, Bird, Blackburne and Potter; while among naturalized English players were Löwenthal, Steinitz, Zukertort, who died in 1888, and Horwitz. This illustrious contingent was reinforced in 1878 by Mason, an Irish-American, who came over for the Paris tournament; by Gunsberg, a Hungarian; and later by Teichmann, who also made England his home. English chess flourished under the leadership of these masters, the chief prizes in tournaments being consistently carried off by the English representatives.

To gauge the progress made by the game since about 1875 it will suffice to give the following statistics. In London Simpson's Divan was formerly the chief resort of chess players; the St George's Chess club was the principal chess club in the West End, and the City of London Chess club in the east. About 100 or more clubs are now scattered all over the city. Formerly only the British Chess Association existed; after its dissolution the now defunct Counties' Chess Association took its place, and this was

superseded by the re-establishment by Mr. Hoffer of the British Chess Association, which again fell into abeyance after having organized three international tournaments—London, 1886; Bradford, 1888; and Manchester, 1890—and four national tournaments. There were various reasons why the British Chess Association ceased to exercise its functions, one being that minor associations did not feel inclined to merge their identity in a central association. The London League was established, besides the Northern Counties' Chess Union, the Southern Counties' Chess Union, the Midland Counties' Union, and associations in most of the counties. All these associations are supported by the affiliated chess clubs of the respective counties. Scotland (which has its own association), Wales and Ireland have also numerous clubs. These are now all affiliated to the British Chess Federation (*q.v.*).

TOURNAMENTS

The first modern International Chess Tournament held in London in 1851 was the forerunner of various similar contests, the most important from 1910 being given below:

- 1910. Hamburg. 1. Schlechter, 2. Duras, 3. Niemzowitsch.
- 1911. San Sebastian. 1. Capablanca, 2. Rubinstein and Vidmar.
- 1911. Carlsbad. 1. Teichmann, 2. Rubinstein and Schlechter.
- 1912. San Sebastian. 1. Rubinstein, 2. Spielmann and Niemzowitsch.
- 1912. Pstyan. 1. Rubinstein, 2. Spielmann, 3. Marshall.
- 1912. Breslau. 1. Duras and Rubinstein, 3. Teichmann.
- 1914. St. Petersburg. 1. Lasker, 2. Capablanca, 3. Alekhin.
- 1914. Mannheim. 1. Alekhin, 2. Vidmar, 3. Spielmann. This tournament was broken off, owing to the outbreak of war.
- 1916. New York. 1. Capablanca, 2. Janowsky, 3. Kostich.
- 1918. Berlin. 1. Vidmar, 2. Schlechter, 3. Mieses.
- 1918. Berlin. 1. Lasker, 2. Rubinstein, 3. Schlechter.
- 1918. Kaschau. 1. Réti, 2. Vidmar, 3. Breyer and Schlechter.
- 1918. New York. 1. Capablanca, 2. Kostich, 3. Marshall.
- 1920. Gothenburg. 1. Réti, 2. Rubinstein, 3. Bogoljubow.
- 1920. Berlin. 1. Breyer, 2. Bogoljubow and Tartakower.
- 1921. Triberg. 1. Alekhin, 2. Bogoljubow, 3. Sämisch and Selesniew.
- 1921. Vienna. 1. Sämisch, 2. Euwe, 3. Breyer.
- 1921. Budapest. 1. Alekhin, 2. Grünfeld, 3. Kostich and Tartakower.
- 1921. The Hague. 1. Alekhin, 2. Tartakower, 3. Rubinstein.
- 1922. Pstyan. 1. Bogoljubow, 2. Alekhin and Spielmann.
- 1922. London. 1. Capablanca, 2. Alekhin, 3. Vidmar.
- 1922. Hastings. 1. Alekhin, 2. Rubinstein, 3. Bogoljubow and Sir G. A. Thomas, Bt.
- 1922. Teplitz-Schönau. 1. Réti and Spielmann, 3. Grünfeld and Tartakower.
- 1922. Vienna. 1. Rubinstein, 2. Tartakower, 3. Wolf.
- 1923. Carlsbad. 1. Alekhin, Bogoljubow and Maróczy.
- 1923. Mährisch-Ostrau. 1. Lasker, 2. Réti, 3. Grünfeld.
- 1924. New York. 1. Lasker, 2. Capablanca, 3. Alekhin.
- 1924. Meran. 1. Grünfeld, 2. Spielmann, 3. Rubinstein.
- 1925. Baden-Baden. 1. Alekhin, 2. Rubinstein, 3. Sämisch.
- 1925. Marienbad. 1. Rubinstein and Niemzowitsch, 3. Torre and Marshall.
- 1925. Breslau. 1. Bogoljubow, 2. Niemzowitsch, 3. Wagner and Rubinstein.
- 1925. Moscow. 1. Bogoljubow, 2. Lasker, 3. Capablanca.
- 1926. Semmering. 1. Spielmann, 2. Alekhin, 3. Vidmar.
- 1926. Dresden. 1. Niemzowitsch, 2. Alekhin, 3. Rubinstein.
- 1926. Budapest. 1. Grünfeld and Monticelli, 3. Knoch, Rubinstein and Takács.
- 1926. Hanover. 1. Niemzowitsch, 2. Rubinstein, 3. Von Holzhausen.
- 1926. Lake Hopatcong. 1. Capablanca, 2. Kupchik, 3. Maróczy.
- 1926. Berlin. 1. Bogoljubow, 2. Rubinstein, 3. Ahues, Grünfeld and Spielmann.
- 1926. Meran. 1. Colle, 2. Spielmann, Canal and Przepiórka.
- 1927. New York. 1. Capablanca, 2. Alekhin, 3. Niemzowitsch.
- 1927. Berlin. 1. Brinckmann, 2. Bogoljubow, Niemzowitsch and Sämisch.
- 1927. Kecskemét. 1. Alekhin, 2. L. Steiner and Niemzowitsch.
- 1927. London. 1. Niemzowitsch and Tartakower, 3. Marshall.
- 1928. Berlin. 1. Niemzowitsch, 2. Bogoljubow, 3. Tartakower.
- 1928. Kissingen. 1. Bogoljubow, 2. Capablanca, 3. Euwe and Rubinstein.

SCHOOLS OF PLAY

Chess has developed various schools of play from time to time. The theory of the game, however, did not advance in proportion to the enormous strides in its popularity. Formerly the theory of play had been enriched by such enthusiasts as Dr. Max Lange, Louis Paulsen, Professor Anderssen, Neumann, Dr. Suhle, Falkbeer, Kieseritzki, Howard Staunton, Dr. Zukertort, W. N. Potter and Steinitz. The most permanent influence on chess theory was exercised by Steinitz. In the days of Morphy and Anderssen

players invariably strove for an attack on the king's position at any cost. Steinitz, however, realized that such attacks were, generally speaking, successful only against inferior opposition and came to the conclusion that the correct strategy was to strive to create weaknesses, however slight, in the hostile position, and by the accumulation of these weaknesses to obtain an opportunity for a decisive combination. This new method he not only preached but practised, and thus was founded the modern school. If to Steinitz credit must be given for founding this school, to other players credit must be given for combining the theory of minute advantages with the old method of rapid development adopted by Morphy and Anderssen. Steinitz preferred a slow development and the building-up of an unassailable (if cramped) position. Dr. Tarrasch, however, had no liking for cramped positions and so strove for rapid development (as Morphy), not to essay a violent and hazardous attack (as Morphy) but to use his rapid development and greater control of space to force his opponent to create those weaknesses which Steinitz had shown how to exploit. This may be said to be the method of the modern school.

In 1913, however, a young Russian master, A. Niemzowitsch, published some articles assailing some of the cardinal points of the Tarrasch creed. Their importance was not sufficiently estimated at the time, for Niemzowitsch had already a reputation for a bizarre style of play, and the outbreak of war next year put an end to discussion of chess theories. But to Niemzowitsch must be given the credit (if credit it be) of founding what is now known as the hypermodern school. The teachings of this school, which has come into prominence since the World War, may be roughly summarised as follows: (i.) "The Golden Rule is that there is no Golden Rule"—in other words, the hypermoderns view generalizations with suspicion. As Richard Réti, one of the most ardent advocates of this school, said in his *Modern Ideas in Chess*, "The hypermoderns are the greatest opponents of routine play." (Richard Réti died June 6, 1929.) (ii.) Tarrasch had laid down the importance of being strong in the centre, holding that a player who has control of the four squares in the centre (*e4, e5, d4, d5*) has an advantage in that he can prevent the deployment of his opponent's pieces from one wing to the other via those squares—the most natural and effective route. The hypermoderns do not, however, immediately hasten to seize control of those squares, preferring to delay that occupation until it can be done (as they consider) more effectively. To that purpose they hold back the centre pawns in the beginning of a game and develop their bishops in posts where they will be likely to aid the subsequent investment of the centre (*e.g.*, at *KKt2* and *QKt2* or *KKt2* and *K3*). The views of the hypermoderns have not, however, been accepted in their entirety by all the masters, many of whom still follow the teachings of the modern school.

The World's Championship.—In the absence of any authority to confer the title of world's champion, it was assumed by Steinitz—and rightly, for he was undoubtedly the strongest player of his day. In his old age, however—in 1894—he was beaten in a match for the championship by a young German player, Dr. Emanuel Lasker. Lasker held the title for 26 years, during which time he defeated redoubtable opponents in Steinitz (a return match), Marshall, Janowsky (twice) and Dr. Tarrasch, and drew with Schlechter. In 1921 a match was arranged at Havana between Lasker and J. R. Capablanca—a Cuban who was on all sides admitted to be Lasker's most dangerous antagonist. Capablanca won by four games to none, with ten draws, Lasker resigning after the 14th game on the grounds that the climate at Havana was highly dangerous to his health. Capablanca, however, did not hold the title for long. In the autumn of 1927, after a struggle lasting nearly three months, he was defeated at Buenos Aires by the Russian master, Dr. Alekhin, who won six games to three, no fewer than 25 being drawn.

Fédération Internationale des Échecs.—This body is the central authority for chess matters. Most of the European countries and the U.S.A. are members. A tournament under the auspices of the Federation was held at Budapest in 1926, and the following year a tournament was held at London between teams, each of four players, representing 16 nations attached to the Fed-

eration. The tournament was won by Hungary with a score of 40 points out of a possible 60. Close behind came Denmark (second) and the British empire (third). Hungary also won a similar tournament held at The Hague in 1928.

Modern British Chess.—The British Chess Federation was instituted in 1904, its first congress being held at Hastings in that year, when a British championship, a ladies' championship and a first-class amateur tournament were played. These competitions have been continued annually at the congresses of the Federation, with the exception of the War period and the years 1922 and 1927, when international tournaments were held in England. The holders of the British championship have been W. E. Napier, H. E. Atkins, R. C. Griffith, F. D. Yates, R. H. V. Scott and Sir G. A. Thomas.

In 1896 and following years matches between representative players of Great Britain and the United States respectively were played by cable, with the following results:

| | | | | |
|---------------------|--------|----|-------------|----|
| 1896. America | won by | 4½ | games to | 3½ |
| 1897. Great Britain | " | 5½ | " | 4½ |
| 1898. Great Britain | " | 5½ | " | 4½ |
| 1899. America | " | 6 | " | 4 |

By winning three consecutive matches Great Britain obtained permanent possession of the trophy. In England chess matches have been played annually since 1873 between the universities of Oxford and Cambridge, seven players on each side. Up to 1928 Oxford won 23 matches, Cambridge 25, and four were drawn.

Literature of the Game.—The most ambitious of early European writings on chess was the work of a Lombard, Jacobus de Cessolis (Jacopo Dacciesole), whose main object, however, though he gives the moves, etc., was to teach morals rather than chess. He was a Dominican friar and his treatise, *Liber de Moribus Hominum et Officiis Nobilium*, was written before the year 1300. It was afterwards translated into several European languages, and in the year 1474 Caxton, under the title of *The Game and Playe of Chesse*, printed an English translation of the French version.

About 1500 we have the *Göttinger Handschrift*, a work containing 12 different openings and 30 problems. The author of this manuscript is not known. Of Lucena, a Spanish author who wrote in or about 1497, we are better informed. His treatise, *Repetición des Amores e Arte de Axedres*, comprises various practical chess matters, including 150 positions, illustrated by 160 well-executed woodcuts. Various of these positions are identical with those in the *Göttinger Handschrift*. In the 16th century works upon the game were written by Damiano, Ruy Lopez and Horatio Gianutio della Mantia; in the 17th century by Salvio, Polerio, Gustavus Selenus, Carrera, Greco, Fr. Antonio and the authors of the *Traité de Lausanne*; in the 18th century by Bertin, Stamma, Ercole del Rio, Lolli, Cozio, Philidor, Ponziani, Stein, van Nyevelt, Allgaier and Peter Pratt; in the 19th century by J. F. W. Koch and C. F. Koch, Sarratt, John Cochrane, Wm. Lewis, Silberschmidt, Ghulam Kassim and James Cochrane, George Walker, A. Macdonnell, Jaenisch, Petroff, von Bilguer, von der Lasa, Staunton, Kling and Horwitz, Bledow, Dubois, Kieseritzki, Max Lange, Löwenthal, Dufresne, Neumann, Suhle, Zukertort, Preti, Steinitz and others.

English chess owes much to W. Lewis and George Walker. But to Howard Staunton must be ascribed the most important share in creating the later popularity which the game achieved in England. Staunton's first work *The Chess Player's Handbook*, was published in 1847, and again (revised) in 1848. For want of further adequate revision many of its variations are now out of date; but taking the handbook as it was when issued, very high praise must be bestowed upon the author. His other works are: *The Chess Player's Text-Book* and *The Chess Player's Companion* (1849) (the latter being a collection of his own games); the *Chess Praxis* (1860, republished in 1903); his posthumous work, *Chess*

Theory and Practice, edited by R. B. Wormald (1876), and various smaller treatises. The laws of the game as laid down in the *Praxis* formed the basis of the rules adopted by the British Chess Association in 1862. Besides editing the *Chess Player's Chronicle* and the *Chess World*, he was the chess editor of the *Illustrated London News* from 1844 till his death in 1874.

BIBLIOGRAPHY.—*Elements of the Game*—Rev. E. E. Cunningham, *The Modern Chess Primer* (1920) gives a very good grounding in the elements of the game and the student should master its contents. *General Treatises*—(a) Elementary: Lawrence H. Dawson, *A Short Guide to Chess* (1923); E. A. Greig, *Pitfalls of the Chess-Board* (revised by W. A. Fairhurst, 1927). (b) Fairly advanced: J. Mason, *The Art of Chess* (1913) and *The Principles of Chess* (1923); Dr. Emanuel Lasker, *Common Sense in Chess* (1896); E. Lasker, *Chess Strategy* (1922). (c) More advanced: Capablanca, *Chess Fundamentals* (1921); Znosko-Borowsky, *The Middle Game in Chess* (1922); Réti, *Modern Ideas in Chess* (1923); Niemzowitsch, *Die Blockade und Mein System* (1925); Kmooh, *Die Kunst der Verteidigung* (The Art of Defence) (1927); Dr. Emanuel Lasker, *Lasker's Manual of Chess* (1927). *End Games*—The elements of the endings are dealt with in both *The Modern Chess Primer* and *The Art of Chess*. Other works which may be recommended to the more advanced student are: Mises, *Chess Endings from Modern Master-Play*; Tattersall, *A Thousand End-Games*; Rinck, *700 Fins de Partie* (1926), and Berger's monumental work *Theorie und Praxis der Endspiele* (2nd ed. 1921). *Openings*—The best work in English is undoubtedly Griffith and White's *Modern Chess Openings* (1925), which gives concisely the state of the theory of the openings. The *Handbuch des Schachspiels* (8th ed. 1916, by Schlechter, with supplement, 1921, by Mises) and *Lärobok i Schack* (1921) are decidedly more voluminous but less up-to-date. A mine of information is Tartakower's *Die Hypermoderne Schachpartie* (1924). Of works dealing with only one opening the following are very useful: J. du Mont, *The Centre Counter and The Centre Game*; Maróczy, *Die Französische Partie* (The French Defence) (1924); Tarrasch, *Die Verteidigung des Damengambits* (The Defence of the Queen's Gambit) (Gouda, 1924) and Tartakower, *Die Zukunftsöffnung* (The Opening of the Future, i.e., Réti's Opening) (1924). Tarrasch's little pamphlet *Der Gegenwärtige Stand der Wichtigsten Eröffnungen* (Present Position of Important Openings) (1919) contains much useful information on the Ruy Lopez, the Queen's Gambit and the Four Knights' Game.

Collections of Games—A very valuable—and, perhaps, the most enjoyable—form of chess study is the careful playing over of well-annotated master games. The following books are recommended: Mr. Blackburne's *Games at Chess* (1899); P. W. Sergeant, *Morphy's Games of Chess* (1916), and *Charousek's Games of Chess* (1919); P. W. Sergeant and W. H. Watts, *Pillsbury's Chess Career* (1923); Maróczy, *Hundert Schachpartien* (1921); Capablanca, *My Chess Career* (1920); Tarrasch, *Dreihunder Schachpartien* (1916) and *Die Moderne Schachpartie* (1916); Dr. Alekhin, *My Hundred Best Games of Chess* (1927). This last is one of the finest chess-books ever written.

History—The best book on the history of the game is H. J. R. Murray, *A History of Chess* (1913). (L. VAN V.; G. E. S.)

PROBLEMS

Chess problems are artificial positions, permitting mate in a specified number of moves, with play involving elements of strategy or beauty. In No. 1, by C. S. Kipping (1891—), player and problemist alike would see the need of advancing the white king to Kt6. The player would be satisfied to win easily in four moves, by 1. K-Kt5, avoiding black's promotion check; whereas the problemist would play 1.K-R5, welcoming check, as

NO. 1.—MATE IN THREE NO. 2.—MATE IN THREE NO. 3.—MATE IN THREE

spice incidental to forcing mate in three. For him, 1.K-Kt5 would be only a "try," defeated by 1.--, R-Ktr.

As far back as chess manuscripts survive, there is recorded the ebb and flow of the problem. Fine works occur among the Arabian compositions in the 9th century, and among Italian sources as early as the 13th. The modern period, however, dates only from 1840, when the problems of an Englishman, Rev. H. Bolton (1793-1873), a Belgian, A. d'Orville (1813—) and the German master player, A. Anderssen (1818-79), heralded a great revival of interest. A collection published in Paris, 1846,

by A. Alexandre (1766-1850), contained 2,000 problems and seemed to leave little for the future to attempt. Yet at this very time the establishment of many chess magazines and columns proved a sufficient stimulus to encourage the study of problems on unprecedented lines.

The years 1845-61 marked the discovery of many important themes. Rev. H. A. Loveday (1815-48), English chaplain at Delhi,

published the famous Indian Problem (No. 2) in 1845. The ambush, 1.B-B1, 2.R-Q2, by which stalemate is avoided and mate attained, trite as it appears to-day, took the problem world by storm. (Originally published as a four-mover, this had black Pawn at Kt4 instead of Kt5, with very inaccurate play.) W. Grimshaw (1832-90) of England, A. Novotny (1829-71) of Austria and J. Plachutta (1883) of Germany experimented with the interference themes which to-day bear their names, while F. Healey (1828-1906), England, published his Bristol Problem, No. 3, in 1861, with its surprising clearance key, 1.R-KR1, preparing for 2.Q-Kt1 and 3.Q-KKt1 mate.

In America, Sam Loyd (1841-1911) composed a great number of celebrated problems, such as No. 4: 1.B-R7, 2.Kt-Kt6. Here the ambush resembles Loveday's, but its purpose is not to prepare for a discovered mate, as in the Indian theme, but to remove once for all the bishop's guard. This way of preventing stalemate has been aptly called a Passive Sacrifice.

The themes of these early problems were little appreciated during the next quarter century, a time of solid but dull growth, when intricacy was being cultivated to the exclusion of strategy. Striking figures were Ph. Klett (1833-1910) in Germany and C. Bayer (1828-97) in Austria. Presently, however, appeared several important problem collections, expounding varied technical views and opening the way to a new era: *The Chess Strategy*, 1881, by Loyd (cf. the later: *Sam Loyd and his Chess Problems*, Leeds, 1913); *Das Schachproblem*, 1884, by J. Berger (1845-); *The Chess Problem Text-Book*, 1886, by B. G. Laws (1861-) and C. Planck (1856-); and *Ceske Ulohy Sachove*, 1888, by J. Pospisil (1861-1916).

Stimulated by Pospisil's book and the influence of J. Dobrusky (1853-1907), the Bohemians increasingly emphasized purity of mate, economy of force and the echo or repeated mate. The list of Bohemian composers is a splendid one, including G. Chochochous (1856-) and L. Vetesnik (1857-). More recently Z. Mach (1877-), F. Dedrle (1878-) and others have carried these elements to further refinement, culminating in M.

Havel (1881-). In No. 5, 1.R-Kr, Kt-Kt2; 2.Q-Kt4+, K-B6; 2.Q-B5+ and P-Q7; 2.R-B3, all lead to "model," or pure and economical, mates, while the two first form a beautiful echo.

Following the teachings of Berger, a kindred interest in mating pictures was cultivated in Germany, but with greater complexity of structure and play. From this developed the "grand manner" of the Old German school and of the related Austrian school, still represented by the veterans K. Erlich (1856-) and M.

Feigl (1871-).

In England the standards of purity, exemplified by Laws and Planck in their individual styles, developed into the magnificent works of the blind Jamaican composer, A. F. Mackenzie (1861-1905), and so into the problems of G. Heathcote (1870-) and P. F. Blake (1873-). No 6 is a splendid example of Heathcote's four-movers. The key is 1.R-KKt3, and white continues 2.Q-Q2, Kt-B6+, Q-K3+, Kt-R6+ or Q-B3 according to black's play. Again an Echo.

In America, Loyd had a worthy successor in W. A. Shinkman (1847-), while other admirable American composers have been H. W. Bettmann (1868-) and O. Wurzburg (1875-). Loyd's style has influenced composers in many other countries, including notably the celebrated Roumanian, W. Pauly (1876-) and several of the Scandinavians.

A recent school has sprung up in Germany, since the publication in 1903 of *Das Indische Problem*, by J. Kohtz (1843-1918). He drew attention to the thematic problems of 1845-61 and encouraged fresh study of all the interference themes. This German problem renaissance has had many distinguished members: W. von Holzhausen (1876-), F. Kohnlein (1879-1916), F. Sackmann (1888-1926) and more recently A. Kraemer (1898-) F. Palatz (1896-) and others. No. 7 is an example of Kohtz's work. The sacrifice key, 1.Kt-Q6, decoys the black bishop, so it can no longer play to Kt4. When it now defends against 2.Q-K2 by 2.---, B-B5, white is enabled to capture it. This decoy to a vulnerable point on a line Kohtz called the Roman Theme.

While of less depth than longer problems, two-movers have enjoyed increasing popularity since the admirable productions of T. Taverner (1856-1928) appeared in England in the '80s and '90s. Mackenzie gave two-movers fresh vitality at the end of the century, drawing attention to the cross-check theme, where black checks, such as those of the knight in No. 8 (Key: 1.B-K4) are countered without recapture of the checking piece. More recently, interferences and pinnings and unpinnings, and then the changed mate, have provided the two-mover with original material. The establishment, 1913-24, by J. F. Magee Jr. (1867-) of the Good Companion club of Philadelphia, encouraged these new two-move forms widely, calling into action many younger men, such as G. Guidelli (1897-1924) and A. Mari (1892-) of Italy, A. Ellerman (1893-) of Argentine Republic, and C. Mansfield (1896-) of England. The changed mate, brought into vogue in England by P. H. Williams (1873-1922), has had an interesting growth, extending more recently to the domain of three-movers. S. Hume's No. 9 is an example of changed promotions, the apparent 1.---, RxR; 2.PxR(B) of the set position being replaced by 1.Kt-R8, RxR; 2.PxR(R) in the real solution.

In general, modern interest in composition and solving no longer centres only on the difficulty, strategy or beauty of individual problems, but embraces the study of whole groups of problems and the classification of their themes. There exist large classified collections, such as that in the custody of G. Hume (1862-), Nottingham, England, with its 150,000 problems and 8,000 thematic subdivisions, and there are many noteworthy books on themes, such as *Simple Two-Move Themes*, Stroud, 1924, by F. B. Feast (1872-) of England, and *The Chess Problem*, Stroud, 1926, by H. Weenink (1892-) of Holland.

Note: This article has not attempted to trace the story of problems other than direct-mates. But the existence should not be overlooked of such important forms as the self-mate (in which the loser wins) or the many original "fairy" types invented and popularized by T. R. Dawson and others. (A. C. W.)

CHEST, a large box of wood or metal with a ninged lid. The term is used for many different kinds of receptacles; and in anatomy is transferred to the portion of the body covered by the ribs and breastbone (see RESPIRATORY SYSTEM). Chests as articles of furniture are of the greatest antiquity. The chest was the common receptacle for clothes and valuables, and was the direct ancestor of the "chest of drawers," which was formed by enlarging the chest and cutting up the front. It was also frequently used as a seat. Indeed, in its origin it took in great measure the place of the chair, which, although familiar enough to the ancients, was

a luxury in the days when the chest was already an almost universal possession. In the early middle ages the rich possessed them in profusion, used them as portmanteaux, and carried them about from castle to castle. These portable receptacles were often covered with leather and emblazoned with heraldic designs. As houses gradually became more amply furnished, chests and beds and other movables were allowed to remain stationary; and the chest finally took the shape in which we best know it—that of an oblong box standing upon raised feet. As a rule it was made of oak, but sometimes of chestnut or other hard wood.

Types.—There are, properly speaking, three types of chest—the domestic, the ecclesiastical and the strong box or coffer. Old domestic chests still exist in great number and some variety, but the proportion of those earlier than the latter part of the Tudor period is very small; most of them are Jacobean in date. Very frequently they were made to contain the store of house-linen which a bride took to her husband upon her marriage. In the 17th century Boulle and his imitators glorified the marriage-coffer until it became a gorgeous casket, almost indeed a sarcophagus, inlaid with ivory and ebony and precious woods, and enriched with ormolu, supported upon a stand of equal magnificence. The Italian marriage-chests (*cassone, q.v.*) were also of a richness which was never attempted in England. The main characteristics of English domestic chests (which not infrequently are carved with names and dates) are panelled fronts and ends, the feet being formed from prolongations of the “stiles” or side posts. A certain number of 17th-century chests, however, have separate feet, either circular or shaped after the indications of a somewhat later style.

There is usually a strong architectural feeling about the chest, the front being divided into panels, which are plain in the more ordinary examples, and richly carved in the choicer ones. The plinth and frieze are often of well-defined *guilloche* work, or are carved with arabesques or conventionalized flowers. Architectural detail, especially the detail of wainscoting, has indeed been followed with considerable fidelity, many of the earlier chests being carved in the linenfold pattern, while the Jacobean examples are often mere reproductions of the pilastered and recessed oaken mantelpieces of the period.

Occasionally a chest is seen which is inlaid with coloured woods, or with geometrical parquetry. Perhaps the most elaborate type of English parquetry chest is that named after the vanished Palace of Nonesuch. Such pieces are, however, rarely met with. The entire front of this type is covered with a representation of the palace in coloured woods. Another class of chest is incised, sometimes rather roughly, but often with considerable geometrical skill.

The more ordinary variety has been of great value to the forger of antique furniture, who has used its carved panels for conversion into cupboards and other pieces, the history of which is not easily unravelled by the amateur who collects old oak. Towards the end of the 17th century chests were often made of walnut, or even of exotic woods such as cedar and cypress, and were sometimes clamped with large and ornamental brass bands and hinges. The chests of the 18th century were much larger than those of the preceding period, and as often as not were furnished with two drawers at the bottom—an arrangement but rarely seen in those of the 17th century—while they were often fitted with a small internal box fixed across one end for ready access to small articles. The chest was not infrequently unpanelled and unornamented, and in the latter period of its history this became the ruling type.

Ecclesiastical Chests.—These appear to have been used almost entirely as receptacles for vestments and church plate, and those which survive are still often employed for the preservation of parish documents. A considerable variety of these interesting and often exceedingly elaborate chests are still left in English

churches. They are usually of considerable size, and of a length disproportionate to their depth. This no doubt was to facilitate the storage of vestments. Most of them are of great antiquity. Many go back to the 14th century, and here and there they are even earlier, as in the case of the coffer in Stoke d'Abernon church, Surrey, which is unquestionably 13th-century work. One of the most remarkable of these early examples is in Newport church, Essex. It is one of the extremely

rare painted coffers of the 13th century, the front carved with an upper row of shields, from which the heraldic painting has disappeared, and a lower row of roundels. Between is a belt of open tracery, probably of pewter, and the inside of the lid is decorated with oil paintings representing the Crucifixion, the Virgin Mary, St. Peter, St. John and St. Paul. The well-known “jewel chest” in St. Mary’s, Oxford, is one of the earliest examples of 14th century work. Many of these ecclesiastical chests are carved with architectural motives—tracery windows most frequently, but occasionally with the linenfold pattern. There is a whole class of chests known as “tilting coffers,” carved with representations of tournaments or feats of arms, and sometimes with a grotesque admixture of chivalric figures and mythical monsters. Only five or six examples of this type are known still to exist in England, and two of them are now in the Victoria and Albert Museum, London. It is not certain that even these few are of English origin—indeed, very many of the chests and coffers of the 16th and 17th centuries are of foreign make. They were imported into England chiefly from Flanders, and were subsequently carved by native artisans, as was the case with other common pieces of furniture of those periods. The *huche* or “hutch” was a rough type of household chest.

Coffer is the word properly applied to a chest which was intended for the safe keeping of valuables. As a rule the coffer is much more massive in construction than the domestic chest;

TYPE OF CHEST USED IN THE DAYS OF THE STAGE COACH FOR TRANSPORTING VALUABLES ACROSS THE AMERICAN PRAIRIES

BY COURTESY OF THE VICTORIA AND ALBERT MUSEUM
A SPANISH TREASURE CHEST OF THE 17TH CENTURY

VENETIAN CHEST OF THE 16TH CENTURY, IN THE MUSEO NAZIONALE OF FLORENCE, ITALY

it is clamped by iron bands, sometimes contains secret receptacles opening with a concealed spring, and is often furnished with an elaborate and complex lock, which occupies the whole of the underside of the lid. Pieces of this type are sometimes described as Spanish chests, from the belief that they were taken from ships belonging to the Armada. However, these strong boxes are frequently of English origin, although the mechanism of the locks may have been due to the subtle skill of foreign locksmiths. A typical example of the treasure chest is that which belonged to Sir Thomas Bodley, and is preserved in the Bodleian

library at Oxford. The locks of this description of chest are of steel, and are sometimes richly damascened.

Another kind of chest in use in earlier days was that signified in the expression a "chest of viols." This took the form of a solidly-constructed, baize-lined press or cupboard, designed to accommodate stringed musical instruments—in the case of a "chest of viols," six viols of varying sizes.

CHESTER, EARLS OF. The important palatine earldom of Chester was first held by a Fleming named Gherbod (fl. 1070), and then from 1071 by Hugh of Avranches (d. 1101), a son of Richard, viscount of Avranches. As the friend of St. Anselm, Hugh showed the customary liberality to religious houses. His life was spent in fighting in Wales and Normandy, and he died on July 27, 1101. Hugh's only son Richard, who was childless, was drowned in the White Ship, in Nov., 1120. Among subsequent holders were Ralph, or Randolph, de Gernon (d. 1153), prominent in the civil wars under Stephen, fighting first on one side and then on the other; and his son Hugh de Kevelioc (1147-81), who shared in the rising against Henry II. in 1173. The most celebrated of the earls was Ralph Ranulf, or Randolph, de Blundevill (c. 1172-1232), who succeeded his father Hugh de Kevelioc in 1181, and was created earl of Lincoln in 1217. He married Constance, widow of Henry II.'s son, Geoffrey, of Brittany, and is sometimes called duke of Brittany and earl of Richmond. He fought in Wales, sided with John against the barons, and fought for Henry III. against the French invaders and their allies. In 1218 he went on crusade to the Holy Land and took part in the capture of Damietta. He died at Wallingford, in Oct. 1232. Stubbs calls him "almost the last relic of the great feudal aristocracy of the Conquest." In the *Vision of Piers Plowman* Ranulf's name is linked with that of Robin Hood. Ranulf being childless, in Nov. 1232 the earldom was granted to his nephew John the Scot, earl of Huntingdon (c. 1207-1237). In 1246 it was annexed to the English crown.

In 1254 Prince Edward, afterwards Edward I., was created earl of Chester, and since then the earldom has always been held by the heirs apparent to the English crown. Since 1399 the earls of Chester have been also princes of Wales, although the act of Richard II. (1398), which created Chester into a principality to be held by the king's eldest son, was revoked by Henry IV.

CHESTER, county borough, city, and the county town of Cheshire, England, 16 m. S. of Liverpool. Pop. (1931) 41,438. It lies in a low plain on the Dee, principally on the north (right) bank, 6 m. above the point at which the river opens out into its wide shallow estuary. It is an important railway centre, the principal lines serving it being the L.M.S.R., G.W.R., L.N.E.R. and Cheshire Lines.

History.—The Roman station of Deva was founded about A.D. 48 by Ostorius Scapula, and from its key position in relation both to the North Wales coastal route and to the northward avenue past the Mersey, it became an important military and commercial centre. In A.D. 78-79 it was the winter-quarters of Agricola, and later became the permanent headquarters of Legio XX. Valeria Victrix. Many inscriptions and remains of the Roman military occupation have been found, and the north and east walls stand in great part on Roman foundations. The Saxon form of the name was Leganceaster. About 614 the city was destroyed by Aethelfrith, and lay in ruins until 907, when Aethelflaed rebuilt the walls and restored the monastery of St. Werburgh. In the reign of Aethelstan a mint was set up at Chester, and in 973 it was the scene of Edgar's triumph when, it is said, he was rowed on the Dee by six subject kings. It resisted the Conqueror, and did not finally surrender until 1070. On the erection of Cheshire into a county palatine after the Conquest, Chester became the seat of government of the palatine earls. The Domesday account of the city includes a description of the Saxon laws under which it had been governed in the time of Edward the Confessor. All the land, except the bishop's borough, was held of the earl, and assessed at fifty hides.

The earliest extant charter, granted by Henry II. in 1160, empowered the burgesses to trade with Durham as freely as they had done in the reign of Henry I. From this date a large collection

of charters enumerates privileges granted by successive earls and later sovereigns. Three from John protected the trade with Ireland. Edward I. granted the citizens the fee-farm of the city at a yearly rent of £100. In the 14th century Chester began to lose its standing as a port through the gradual silting up of the Dee estuary, and the city was further impoverished by the inroads of the Welsh. Continued misfortunes led to reductions of fee-farm by Richard II. and by Henry VI., who also made a grant for the completion of a new Dee bridge, the old one having been swept away by an unusually high tide. Henry VII. reduced the fee-farm to £20, and in 1506 granted "the Great Charter," which constituted the city a county by itself, and incorporated the governing body under the style of a mayor, twenty-four aldermen and forty common councilmen. This charter was confirmed by James I. and Charles II. The charter of Hugh Lupus to the abbey of St. Werburgh includes a grant of the tolls of the fair at the feast of St. Werburgh for three days, and a subsequent charter from Ranulf de Blundevill (12th century) licensed the abbot and monks to hold their fairs and markets before the abbey gates. Friction between the abbot and civic authorities lasted until, in the reign of Henry VIII., it was decreed that the right of holding fairs was vested exclusively in the citizens. Charles II. in 1685 granted a cattle-fair to be held on the first Thursday in February. The city is divided into four principal blocks by the four principal streets—Northgate Street, Eastgate Street, Bridge Street and Watergate Street, which radiate at right angles from the Cross, and terminate in the four gates. These four streets exhibit in what are called "the Rows" a characteristic feature of the city. In Eastgate Street, Bridge Street and Watergate Street, the Rows exist on each side of the street and form continuous galleries open to the street, from which they are approached by flights of steps. The Rows are flagged or boarded under foot and ceiled above, thus forming a covered way, standing in the same relation to the shops, which are at their back, as the foot pavement does in other towns. On the west side of Northgate Street, on the other hand, the Row is formed out of the ground floor of the houses, having cellars beneath. The Rows and the old half-timbered houses combine to give the city a picturesque and individual character. Among the ancient houses are Derby House, bearing the date 1591, Bishop Lloyd's house, and God's Providence House in Watergate Street, and the Bear and Billet in Lower Bridge Street; the three last date from the 17th century. A mortuary chapel of the early part of the 13th century exists in the basement of a house in Bridge Street.

Chester is the only city in England that still possesses its walls perfect in their entire circuit of 2 m. The gateways have all been rebuilt at various dates: the north and east gates on the site of the Roman gates. The Grosvenor bridge, a single span of stone 200 ft. in length, one of the largest in Europe, carries the road to Wrexham and Shrewsbury over the Dee on the south-west; while there is also an old bridge of seven arches. The castle, with the exception of "Caesar's Tower," and a round tower with adjacent buildings, was taken down in the 18th century, and replaced by a barracks, county hall, gaol and assize courts.

The cathedral church of Christ and the Virgin Mary stands towards the north of the city within the walls on an ancient site. In 1093 Hugh Lupus, earl of Chester, richly endowed the original foundation as a Benedictine monastery. The bishops of Mercia had apparently a seat at Chester, but the city had ceased to be episcopal, until in 1075 Peter, bishop of Lichfield, removed his seat thence to Chester, having for his cathedral the collegiate church of St. John (*see later*). The see, however, was moved again to Coventry (1102), but Cheshire continued subject to Lichfield until in 1541 Chester was erected into a bishopric by Henry VIII., the church of the dissolved abbey of St. Werburgh becoming the cathedral. The diocese covers nearly the whole of Cheshire, with small portions of Lancashire and Staffordshire. The cathedral, while not in the first rank architecturally, gains in beauty from the tones of its red sandstone walls and from its picturesque close. It is cruciform with a central tower 127 ft. high. The nave is short (145 ft.), being of six bays; the southern arcade is Decorated; while the northern differs in detail. The basement of the north-western tower is Norman and formed part

of Hugh Lupus' church. The north transept also retains Norman work, and its size shows the original plan, limited by the existence of the conventual buildings to the north. The south transept has aisles, with Decorated and Perpendicular windows. The fine organ stands on a screen across the north transept. The choir is a fine example of transitional Early English Decorated enhanced by the ancient carved wooden stalls unsurpassed in England. The Lady Chapel, east of the choir, is of rich Early English workmanship. Of the conventual buildings the cloisters are Perpendicular. The chapter-house, entered by a beautiful vestibule from the east cloister, is Early English (c. 1240). The refectory, adjoining the north cloister, is of the same period, with Perpendicular insertions; it has been curtailed in size, but retains its beautiful Early English lector's pulpit. An early Norman chamber, with massive pillars and vaulting, adjoins the west cloister, and may be the substructure of the abbot's house. The abbey gateway is of the 14th century. Within the walls there are several churches of ancient foundation: St. Peter's is said to occupy the site of a church erected by Aethelflaed, queen of Mercia, and St. Mary's dates from the 12th century. The church of St. John, outside the walls, which became the cathedral in 1075, is a massive early Norman structure, with later additions and restorations. It was a collegiate church until 1547. The Grosvenor Museum and School of Art, the foundation of which was suggested by Charles Kingsley the novelist, when canon of Chester cathedral, contains local antiquities and a fine collection of the fauna of Cheshire. The King's school, founded by Henry VIII. (1541), was reorganized on the lines of a public school in 1873. Other educational institutions include the diocesan training college. Roodie, a level tract by the river at the base of the city wall, is appropriated as a race-course. An annual race-meeting is held in May. The town gains in prosperity from its large number of tourists. Other industries, metal-working, tobacco and food production are carried on without the walls. There is some shipping on the Dee but the river is principally used for pleasure vessels and rowing. The city of Chester parliamentary division, returning one member, includes the rural district of Chester and the urban district of Hoole. The area of the county borough is 2,862 acres. In 1553 Chester first returned two members to parliament. By the Redistribution Act of 1885 the representation was reduced to one member. The trades of tanners, skimmers and glove-makers existed at the time of the Conquest, and the importation of marten skins is mentioned in Domesday. In the 14th century the woollen trade was considerable, and in 1674 weavers and wool-combers were introduced into Chester from Norwich. The restoration of the channel of the Dee opened up a flourishing trade in Irish linen, which in 1786 was at its height, but from that date gradually diminished.

See *Victoria County History, Cheshire*; R. H. Morris, *Chester in the Plantagenet and Tudor Reigns* (Chester, 1894); Joseph Hemingway, *History of the City of Chester* (2 vols., Chester, 1831).

CHESTER, a city of Delaware county, Pennsylvania, U.S.A., on the Delaware river, 13m. S.W. of Philadelphia. It is on Federal highway 13, and is served by the Baltimore and Ohio, the Pennsylvania and the Reading railways. The population in 1920 was 58,030, of whom 11,292 were foreign-born white and 7,125 were negroes; and was 59,164 in 1930 Federal census. Chester has a good harbour, with considerable commerce. It has one of the largest shipbuilding yards in the United States, a Ford assembly and shipping plant and eight large steel-casting plants. Other manufactures of importance are cotton, silk and woollen goods, paper, plaster, iron, cutlery, lace, hosiery and steel tubing. The total factory output in 1925 was valued at \$70,557,135. The assessed valuation of property in 1927 was \$67,903,696. On the edge of the city is Crozer Theological seminary (Baptist), founded in 1867 by the family of John P. Crozer (1793-1866). Settled about 1645 by the Swedes, who called it Upland, Chester is the oldest town in Pennsylvania. It was the seat of the Swedish courts until 1682, when William Penn arrived. The spot where he landed is marked by a memorial stone, and the house he occupied for a time (built in 1683) still stands. The old city hall (1724) is one of the oldest public buildings in the country. After the battle of Brandywine Washington retreated to Chester, and

here wrote his account of the battle. Soon after that it was occupied by the British. It was incorporated as a borough in 1701, and received a city charter in 1866. Its period of rapid growth began with the introduction of large manufacturing interests about 1850. In 1850 the population was 1,667; in 1880, 14,997; in 1900, 33,988. Between 1910 and 1920 it increased 50.6%. Annexations of territory have brought the area to 4.78 sq.m.

CHESTER, a city of South Carolina, U.S.A., in the foot-hills of the Blue Ridge mountains, 65m. N.W. of Columbia; the county seat of Chester county. It is on Federal highway 21, and is served by the Carolina and North-western, the Lancaster and Chester, the Seaboard Air Line, and the Southern railways. The population in 1920 was 5,557, of whom 2,153 were negroes, and was 5,528 in 1930 by Federal census. Chester is advantageously situated between the hydro-electric developments of the Broad and the Catawba rivers. It manufactures cotton yarn and cloth, cotton oil, overalls, machinery, implements, and various other articles, and has granite monument works. It was settled about 1732, was incorporated as a town in 1849 and as a city in 1893.

CHESTERFIELD, PHILIP DORMER STANHOPE, 4th EARL OF (1694-1773), son of Philip Stanhope, 3rd earl (1673-1726), and Elizabeth Savile, daughter of George Savile, marquess of Halifax, was born in London on Sept. 22, 1694. The care of the boy devolved upon his grandmother, the marchioness of Halifax. His education, began under a private tutor, was continued (1712) at Trinity Hall, Cambridge; here he remained little more than a year, but seems to have acquired a considerable knowledge of ancient and modern languages. His university training was supplemented (1714) by a continental tour, untrammelled by a governor; at The Hague his ambition for the applause awarded to adventure made a gamester of him, and at Paris he began, from the same motive, that worship of the conventional Venus, the serious inculcation of which has earned for him the largest and most unenviable part of his reputation.

The accession of George I. brought him back to England. His relative, James Stanhope (afterwards 1st Earl Stanhope), the king's favourite minister, procured for him the place of gentleman of the bedchamber to the prince of Wales. In 1715 he entered the House of Commons as Lord Stanhope of Shelford and member for St. Germans. In 1726 his father died, and Lord Stanhope became earl of Chesterfield. He took his seat in the Upper House, and his oratory, never effective in the Commons by reason of its want of force and excess of finish, at once became a power. In 1728 Chesterfield was sent to The Hague as ambassador. In this place his tact and temper, his dexterity and discrimination, enabled him to do good service, and he was rewarded with Walpole's friendship, a Garter and the place of lord high steward. In 1732 there was born to him, by a certain Mlle. du Bouchet, the son, Philip Stanhope, for whose advice and instruction were afterwards written the famous *Letters*. He negotiated the second treaty of Vienna in 1731 and in the next year, being somewhat broken in health and fortune, he resigned his embassy and returned to England. A few months' rest enabled him to resume his seat in the Lords, of which he was one of the acknowledged leaders. He supported the ministry, but his allegiance was not the blind fealty Walpole exacted of his followers. The Excise bill, the great premier's favourite measure, was vehemently opposed by him in the Lords and by his three brothers in the Commons. Walpole bent before the storm and abandoned the measure; but Chesterfield was summarily dismissed from his stewardship. For the next two years he led the opposition in the Upper House, leaving no stone unturned to effect Walpole's downfall. In 1741 he signed the protest for Walpole's dismissal and went abroad on account of his health. He visited Voltaire at Brussels and spent some time in Paris, where he associated with the younger Cr billon, Fontenelle and Montesquieu. In 1743 Walpole fell, and Carteret was his real, though not his nominal, successor. Although Walpole's administration had been overthrown largely by Chesterfield's efforts the new ministry did not count Chesterfield either in its ranks or among its supporters. He remained in opposition, distinguishing himself by the courtly bitterness of his attacks on George II., who learned to hate him

violently. In 1743 a new journal, *Old England; or, the Constitutional Journal*, appeared. For this paper Chesterfield wrote under the name of "Jeffrey Broadbottom." A number of pamphlets, in some of which Chesterfield had the help of Edmund Waller, followed. His energetic campaign against George II. and his government won the gratitude of the dowager duchess of Marlborough, who left him £20,000 as a mark of her appreciation. In 1744 the king was compelled to abandon Carteret, and the coalition or "Broad Bottom" party, led by Chesterfield and Pitt, came into office. In the troublous state of European politics the earl's conduct and experience were more useful abroad than at home, and he was sent to The Hague as ambassador a second time. The object of his mission was to persuade the Dutch to join in the War of the Austrian Succession and to arrange the details of their assistance. The success of his mission was complete; and on his return a few weeks afterwards he received the lord-lieutenancy of Ireland—a place he had long coveted.

Short as it was, Chesterfield's Irish administration was of great service to his country, and is unquestionably that part of his political life which does him most honour. To have conceived and carried out a policy, which, with certain reservations, Burke himself might have originated and owned, is no small title to regard. The earl showed himself finely capable in practice as in theory, vigorous and tolerant, a man to be feared and a leader to be followed; he took the government entirely into his own hands, repressed the jobbery traditional to the office, established schools and manufactures, and at once conciliated and kept in check the Orange and Roman Catholic factions. In 1746, however, he had to exchange the lord-lieutenancy for the place of Secretary of State. With a curious respect for those theories which his familiarity with the secret social history of France had caused him to entertain, he hoped and attempted to retain a hold over the king through the influence of Lady Yarmouth. The influence of Newcastle and Sandwich, however, was too strong for him; he was thwarted and over-reached; and in 1748 he resigned the seals. He declined any knowledge of the *Apology for a late Resignation*, in a *Letter from an English Gentleman to his Friend at The Hague*, which ran through four editions in 1748, but there is little doubt that he was, at least in part, the author.

The dukedom offered him by George II., whose ill-will his fine tact had overcome, was refused. He continued for some years to attend the Upper House and to take part in its proceedings. In 1751, seconded by Lord Macclesfield, president of the Royal Society, and Bradley, the eminent mathematician, he distinguished himself greatly in the debates on the calendar, and succeeded in making the new style a fact. Deafness, however, was gradually affecting him and he withdrew little by little from society and the practice of politics. In 1755 occurred the famous dispute with Johnson over the dedication to the *English Dictionary*. In 1747 Johnson sent Chesterfield, who was then Secretary of State, a prospectus of his *Dictionary*, which was acknowledged by a subscription of £10. Chesterfield apparently took no further interest in the enterprise, and the book was about to appear when he wrote two papers in the *World* in praise of it. It was said that Johnson was kept waiting in the anteroom when he called while Cibber was admitted. In any case the doctor had expected more help from a professed patron of literature, and wrote the earl the famous letter in defence of men of letters. Chesterfield's "respectable Hottentot," now identified with George, lord Lyttelton, was long supposed, though on slender grounds, to be a portrait of Johnson. During the 20 years of life that followed this episode, Chesterfield wrote and read a great deal, but went little into society.

In 1768 died Philip Stanhope, the child of so many hopes. His death was an overwhelming grief to Chesterfield, and the discovery that he had long been married to a lady of humble origin must have been galling in the extreme to his father after his careful instruction in worldly wisdom. Chesterfield, who had no children by his wife, Melusina von Schulemberg, illegitimate daughter of George I., whom he married in 1733, adopted his godson, a distant cousin, named Philip Stanhope (1755-1815), as heir to the title and estates. His famous jest (which even

Johnson allowed to have merit) "Tyrawley and I have been dead these two years, but we don't choose to have it known"—is the best description possible of his humour and condition during the latter part of this period of decline. To the deafness was added blindness, but his memory and his fine manners only left him with life; his last words, "Give Dayrolles a chair," prove that he had neither forgotten his friend nor the way to receive him. He died on March 24, 1773.

As a politician and statesman, Chesterfield's fame rests on his short but brilliant administration of Ireland. As an author he was a clever essayist and epigrammatist. But he stands or falls by the *Letters to his Son*, first published by Stanhope's widow in 1774, and the *Letters to his Godson* (1890). The *Letters* are brilliantly written—full of elegant wisdom, of keen wit, of admirable portrait-painting, of exquisite observation and deduction. Against the charge of an undue insistence on the external graces of manner Chesterfield has been adequately defended by Lord Stanhope (*History*, iii. 34). Against the often iterated accusation of immorality, it should be remembered that the *Letters* reflected the morality of the age, and that their author only systematized and reduced to writing the principles of conduct by which, deliberately or unconsciously, the best and the worst of his contemporaries were governed.

See Chesterfield's *Miscellaneous Works* (2 vols. 1777); *Letters to his Son*, etc. ed. by Lord Mahon (5 vols. 1845-53, re-issued by the Navarre Society in 1926); and *Letters to his Godson* (1890) (ed. by the earl of Carnarvon). There are also eds. of the first series of letters by J. Bradshaw (3 vols. 1892) and Mr. C. Strachey (2 vols. 1901). In 1893 a biography, including numerous letters first pub. from the Newcastle Papers, was issued by Mr. W. Ernst; and in 1907 appeared an elaborate *Life* by W. H. Craig. See also *The Letters of Lord Chesterfield to Lord Huntingdon*, with intro. by A. F. Steuart (1923); R. Coxon, *Chesterfield and His Critics*, with selected essays and unpublished letters by Chesterfield (1925).

CHESTERFIELD, a market town and municipal borough in the Chesterfield parliamentary division of Derbyshire, England, 24 m. N. by E. of Derby by rail. Pop. (1931) 64,146. It is doubtful whether it was a Roman station. Chesterfield (Cestrefeld) owes its present name to the Saxons. It is mentioned in Domesday only as a bailiwick of Newbold. In 1204 John granted to the town all the privileges of a free borough enjoyed by Nottingham and Derby; but before this it seems to have had prescriptive borough rights. In 1598 it was incorporated by Elizabeth under the style of a mayor, six brethren and 12 capital burgesses, and was so governed till the Municipal Act, 1835. In 1204 John granted two weekly markets, on Tuesday and Saturday, and an annual fair of eight days at the feast of the Exaltation of the Holy Cross (Sept. 14). This fair, which is still held, and another on Palm Tuesday are mentioned in the *quo warranto* roll of 1330. The Tuesday market has long been discontinued. In 1266 the town was the scene of a battle between the royal forces and the barons. In 1586 it suffered from the plague, and the parliamentary forces were overthrown here during the Civil War.

Chesterfield lies at the junction of the Rother and Hipper, in an industrial district. The church of St. Mary and All Saints belongs principally to the Decorated period. It has a wooden spire, covered with lead, 230 ft. high, and possesses also an apsidal Decorated chapel. The Stephenson Memorial Hall (1879) commemorates George Stephenson, the engineer. The Grammar school was founded in 1574. The industries of the town include manufactures of cotton, silk, earthenware, machinery and tobacco, with brass and iron founding; slate and stone are quarried and there are coal, iron and lead mines in the neighbourhood.

CHESTER-LE-STREET, urban district in the county of Durham, England, near the river Wear, where the latter changes its northward course and turns eastward to the sea. The town is 6m. north of the city of Durham on the L. N. E. R. Pop. (1931) 16,639.

Chester-le-Street was a station on a branch of the Roman north road. Under the name of *Cunecastre* it was made the seat of a bishop in 882, and continued to be the head of the diocese till the Danish invasion of 995. During that time the church was the repository of the shrine of St. Cuthbert, which was then removed to Durham. The parish church of St. Mary and St. Cuthbert is

an interesting building formerly collegiate, with a remarkable series of monumental tombs. The proximity of the Durham coal-field and iron works gives employment to a large section of the population.

CHESTERTON, GILBERT KEITH (1874-), English journalist and author, was born in London on May 29, 1874. He was educated at St. Paul's school, where, at an unusually early age, he gained the "Milton" prize for English verse. He left school in 1891 with the idea of studying art. But though he early developed, and indeed retained, a talent for draftsmanship of a very distinctive kind, his natural bent was literary, and he went through the usual apprenticeship of free-lance journalism, occasional reviewing and work in a publisher's office.

In 1901 he married Frances Blogg. In 1900 after having produced a volume of poems, *The Wild Knight* (1900), which led good critics to expect great things of him as a poet, he became a regular contributor of signed articles to *The Speaker* and the *Daily News*. From the first he stood out as the protagonist of revolt against the *fin-de-siècle* egotism and the weary omniscience of the previous generation, expressing for it the virile contempt of normal platitudinous man in a style unconventional, swash-buckling and dogmatic. As Addison turned the weapons of fashionable folly against itself by making vice ridiculous, so Chesterton laughed loud and long at the *blasé* self-sufficiency and the dingy little failings of the late Victorian wits. Never was conventionality defended in a manner so unconventional. Hence the legend of Chesterton as a "master of paradox," which originated among older Victorian contemporaries and persisted far longer than it was reasonable to expect, partly perhaps because the subject of the legend was more tickled by it than he need have been. Chesterton's early studies in this vein were reprinted in a series of volumes, *The Defendant* (1901), *Twelve Types* (1902), and *Heretics* (1905). Meanwhile he had laid the foundations of a more enduring reputation as a literary critic by his brilliant study of Browning in the "English Men of Letters" series (*Robert Browning*, 1903). This was followed (1906) by *Charles Dickens*, which has been described as "one of the best critical studies in the language." *Orthodoxy* (1908) and *What's Wrong with the World* (1910) succeeded *Heretics* as essays in religious thought and contemporary politics. To his hatred of the Victorian pessimists there had by now been added a hatred of Victorian economics. He had begun life as an orthodox Liberal but was seized with a growing distrust of the reality of modern party politics, coupled with a fierce dislike of the industrial capitalism which he found dominant in the two old parties. He reacted, however, ultimately as fiercely from Socialism, and, in company with Hilaire Belloc and others, propagated the Distributist theories with which his name is associated.

In fiction his fancy found free play, and the medium was well suited to the expression of his ideas. He produced *The Napoleon of Notting Hill* (1904), a fantastic dream-history of civil wars between the suburbs of London, in which the shattering sanity of romantic man is once more vindicated; *The Club of Queer Trades* (1905), wherein the germs of his later success in detective fiction may be noticed; *The Man Who was Thursday* (1908), and *The Ball and the Cross* (1909). In these works the tendency to commingle his philosophy with his fiction became even greater. An earlier generation than Chesterton's would have called the books allegories, probably with the enthusiastic assent of the author. During the same period Chesterton produced a quantity of verse, some good, some bad—none of it indifferent. At its best it is very good indeed. A well-known English critic once observed of his light verse that, whereas there had been many in all ages who could write comic verse, Chesterton was one of the very few who could write comic poetry. The compliment was deserved. His more serious verse has been held to give him rank as the last of the great rhetorical poets. Like all rhetorical poets he is sometimes tinselly, but his best poems show what rhetoric can be at its best. Of these are "Lepanto" (1911) and "A Song of the Wheels," written during the railway strike of 1911. *The Ballad of the White Horse* (1911) is uneven, but contains some of his finest work.

The year before the World War saw the issue of his *Victorian Age in Literature* (1913), in which he showed that he could write a hand-book without loss of those qualities of penetrating analysis and generous appreciation which he had already brought to the work of literary criticism. An excellent example is the way in which he put the case for Swinburne, a poet with whom fundamentally he had little in common. In the same year he produced *Magic*, a fanciful play in three acts, which was deservedly successful. It is a matter for surprise and regret that he never, until 1927, followed up this initial attempt at play-writing. Detective fiction claimed him for her own, and his "Father Brown" series (1911, 1914, 1926 and 1927) and *The Man Who Knew Too Much* (1922) showed that he could couple even the writing of sensational mystery stuff with an expression of the views which he had made peculiarly his own. *The Flying Inn* (1914) is yet another of his socio-political "allegories," interspersed with what are perhaps the most charming of his light verses, afterwards republished in *Wine, Water and Song* (1915). Another work of the same kind is *Manalive* (1915).

In 1922 an event happened which was of the utmost moment in Chesterton's life. He was received into the Roman Catholic Church. It was the natural result of a spiritual and intellectual development such as his had been; and it cannot be said profoundly to have modified this development, of which it was the outcome. For the student of his works in the future it will not be necessary sharply to divide, as has to be done in some cases, his "Catholic" from his "pre-Catholic" writings. The general doctrines which he was preaching in 1927 he was preaching in 1906. *Charles Dickens* might have been written by a Catholic, and *St. Francis of Assisi* (1923) by the "pre-Catholic" Chesterton.

During the War Chesterton published little of permanent value. His volume of suggestive and brilliant historical essays, called by some strange oversight *A Short History of England* (1917), is most worthy of note. Of his later works, *The Superstition of Divorce* (1920), *The New Jerusalem* (1920), *What I saw in America* (1922), *St. Francis of Assisi* (1923), *William Cobbett* (1925), *The Everlasting Man* (1925), *The Judgment of Dr. Johnson* (1927), *R. L. Stevenson* (1927), *Generally Speaking* (1929), and *The Poet and the Lunatics* (1929) are the chief.

It is difficult in the limits of such an article to appraise Chesterton's work adequately; but it is not difficult to see how his early reaction against the ideals (or lack of ideals) of the materialist civilization of the 19th century led him inevitably to champion the causes, lost or other, which he has championed (and here, be it said, that it is difficult to imagine that any cause is lost when Chesterton is defending it). He objected not so much to the civilization (for him, too, "Romance brought up the 9.15") as to the complacency of those who thought it the only, or the highest, form of civilization. And yet he could appreciate the great Victorians as could few of his contemporaries. The generation after the War returned to Trollope and Wilkie Collins. But it was Chesterton who was showing them the way 15 years earlier. Indeed, it is this quality of appreciating his opponent, which he himself so praises in Pope, which makes the literary Chesterton at once so lovable a personality and so deadly an antagonist.

If a prediction may be ventured, Chesterton will be remembered longest by his poems and his work in literary criticism. Many will regret that he tried his hand so little at play-writing, and spent so much time on polemical journalism. Nearly all will deplore the volume of his output. None will question the reality of his achievement at its highest, or the strength and purity of his influence upon the literature and thought of his time.

See *G. K. Chesterton: a Criticism* (published anonymously, 1908); "A Canterbury Pilgrim" in John Freeman, *English Portraits and Essays* (1924). (E. I. J.)

CHESTERTON, a parish and suburb in the north-east of Cambridge borough, Cambridgeshire, England, on the river Cam. Pop. (1931) 11,611. The church of St. Andrew is Decorated and Perpendicular, with remains of frescoes. The Cambridge university boat club and the various college boat clubs have boat-houses along the river. Market gardening is carried on in the neighbourhood. Pop. rural district (1931) 26,877.

CHESTNUT. This word is used for the common name of trees of the genus *Castanea* (family Fagaceae) or the edible nuts of these trees. The term "sweet chestnut" is used to distinguish it from "horse chestnut," an entirely unrelated plant but having fruit that resembles the edible chestnut.

There are three main species of chestnut as follows: (1) *Castanea sativa* (vulgaris), known as European, French, Spanish or Italian chestnut, which inhabits forests in temperate regions of Asia and Europe; (2) *Castanea dentata*, the American chestnut, which occurs in North America from Maine to southern Michigan and southward to North Carolina and central Mississippi; (3) *Castanea crenata*, the Japanese chestnut, native to Japan and China.

Chestnuts are deciduous trees with large-toothed, lanceolate leaves and with the staminate and pistillate flowers borne separately, the staminate ones occurring in long catkins and the pistillate as a prickly involucre. The latter are borne three together invested by green bracts which, as the fruit matures, grow to form the tough prickly envelope surrounding the group of nuts. The nuts have long been an important article of food, eaten roasted, boiled, mashed or otherwise as a vegetable. In the raw

state they have a sweet taste but are difficult of digestion. The timber bears a striking resemblance to that of oak but may be distinguished by the numerous fine medullary rays. It is very commonly used as finishing lumber because it has prominent grain and takes a high polish.

A very serious bark disease caused by a fungus, *Endothia parasitica*, is sweeping the chestnut forests of the United States. It started in New York among material imported from Asia and in 1928 had gone as far west as Ohio. European species are apparently more resistant than American and it is hoped that through

selection or hybridization entirely resistant strains may be found. Chestnut trees are being planted to form commercial orchards in the central States but since susceptible strains have been used they will most likely be killed eventually by the blight disease. About 10 important American strains have been selected and propagated to use in the commercial orchards. About 20 strains of the European species and an equal number of the Japanese

species are named and grown throughout the world. The Japanese types have been affected with the blight fungus for centuries, but they are sufficiently resistant to prevent the organism from killing the trees. (P. W. Z.)

CHETTLE, HENRY (c. 1560–1607), English dramatist and miscellaneous writer, was the son of Robert Chettle, a London dyer. He was apprenticed in 1577 to a printer, and in 1589 became a partner with William Hoskins and John Danter. In 1592 he published Robert Greene's *Groat'sworth of Wit*. In the preface to his *Kind Herts Dreame* (end of 1592) he admits his editorship of that pamphlet, and incidentally he apologized to three persons (one of them commonly identified with Shakespeare) who had been abused in it. As early as 1598 Francis Meres includes him in his *Palladis Tamia* as one of the "best for comedy," and between that year and 1603 he wrote or collaborated in some forty-eight pieces. He seems to have been generally in debt, judging from numerous entries in Henslowe's diary of advances for various purposes, on one occasion (Jan. 17, 1599) to pay his expenses in the Marshalsea prison, on another (March 7, 1603) to get his play out of pawn. Of the plays usually attributed to Chettle's sole authorship only one was printed. This was *The Tragedy of Hoffmann: or a Revenge for a Father* (played 1602; printed 1631), a share in which Mr. Fleay assigns to Thomas Heywood. It has been suggested that this piece was put forward as a rival to Shakespeare's *Hamlet*. *The Pleasant Comedie of Patient Grissill* (1599), in which he collaborated with Thomas Dekker and William Haughton, was reprinted by the Shakespeare Society in 1841. In Nov. 1599 Chettle receives ten shillings for mending the first part of "Robin Hood," i.e. *The Downfall of Robert, Earl of Huntingdon*, by Anthony Munday; and in the second part, which followed soon after and was printed in 1601, *The Death of Robert, Earle of Huntingdon*, he collaborated with Munday. Both plays are printed in Dodsley's *Select Collection of Old English Plays* (ed. W. C. Hazlitt, vol. viii.). Chettle died before the appearance of Dekker's *Knight's*

Conjuring in 1607, for he is there mentioned as a recent arrival in limbo.

Hoffmann was edited by H. B. (arrett) L. (ennard) (1852), by Richard Ackermann (Bamberg, 1894), and J. S. Farmer in *Old English Plays, Students' Facsimile Edition* (1913).

CHETWODE, SIR PHILIP WALHOUSE (1869–), British soldier, was born on Sept. 21, 1869, and in Nov. 1889 was commissioned to the 19th Hussars from the militia. He saw active service in Burma and South Africa, and later became assistant military secretary to Sir John French at Aldershot. Promoted to the command of the 5th Cavalry Brigade in May 1914, his brigade accompanied the Expeditionary Force to France and helped to cover the retreat from Mons, bringing off at Cérizy one of the rare cavalry charges of the World War. He went to Egypt to command the Desert column in 1916, and won distinction by the decisive surprise attack at Rafah, which finally freed Sinai from the Turks. After the second battle of Gaza in April 1917 he succeeded Gen. Dobell in command of the whole eastern force. When Gen. Allenby came out to take over the supreme command he based his plan on Chetwode's plans, and the latter, commanding the XX. Army Corps after the reorganization of the forces, played a distinguished part in the advance to Jerusalem and in the crowning victory in Sept. 1918. Shortly after the war, Chetwode was appointed military secretary at the War Office, then in Sept. 1920 succeeded Gen. Harington as deputy chief of the imperial staff, and two years later became adjutant-general to the forces. This post he gave up in April 1923, taking the Aldershot command, which he retained until 1927. Sir Philip Chetwode holds many English and foreign decorations.

CHEVALIER, ALBERT (1861–1923), English music-hall artist, began his connection with the variety stage while still a child. In 1869 he appeared at a "penny-reading" at Cornwall Hall, Notting Hill. After a brief experience as a clerk in a newspaper office, and as a pupil teacher, he appeared for a short time in 1877 with the Kendals and the Bancrofts. For some time he played "legitimate" parts with Hare (*q.v.*), Willie Edouin and others, and during his association with Edouin (1888–89) at the Strand theatre he introduced in burlesque his first cockney song, "Our 'armonic Club." The year 1891 was the turning point of his career, when he deserted the "legitimate" stage and appeared at the London Pavilion as a music-hall entertainer. Thereafter he speedily won the place to which his genius entitled him, among the first artistes of his generation. He toured throughout Great Britain and the United States, and in addition gave over 1,000 special recitals at the small Queen's Hall. As singer, composer or part composer, his name is associated with between 70 and 80 songs. In addition he wrote some 14 plays and sketches. In 1906 he appeared with Yvette Guilbert at the Duke of York's theatre, and in the name part of Sir James Barrie's *Pantaloons*. His last appearance was in Nov. 1922, in a play, *My Old Dutch*, written by himself and Arthur Shirley on the basis of his own famous song. He died on July 10, 1923. Chevalier's best known songs are: "Mrs. 'Enery 'Awkins," "Knocked 'em in the Old Kent Road," "My Old Dutch," "A Fallen Star," "Our Little Nipper," "Fair Flo." He wrote two records of his own experiences, *Before I Forget* (1901), and *Uninitiated* (1906).

In his own special line Chevalier is generally recognized as being an artist of the first rank. While not possessing the vast range of a Marie Lloyd, he yet developed his own specialty as it had never before been developed, and presented real character sketches of the life of the people, emphasizing the grave as well as the gay and bringing tears as readily as laughter. Subsequent cockney comedians have imitated his humour. None has even endeavoured to compete with him in the delineation of the pathetic. Another striking feature of his songs was the tuneful and haunting melodies to which they were set. This was a real feature of the music-hall stage in an era when the comedian tended to sing his patter to the baldest of extemporizations. (E. I. J.)

CHEVALIER, MICHEL (1806–1879), French economist, was born at Limoges. In his early manhood, while employed as an engineer, he became a convert to the theories of Saint-Simon; these he ardently advocated in the *Globe*, the organ of the Saint

Simonians, which he edited until his arrest in 1832 on a charge of outraging public morality by its publication. He was sentenced to a year's imprisonment, but was released in six months through the intervention of Thiers, who sent him on a special mission to the United States to study the question of land and water transport. In 1836 he published the letters he wrote from America to the *Journal des Débats*, as *Lettres sur l'Amérique du Nord*, and in 1838 published *Des intérêts matériels de la France*. In 1850 he became a member of the Institute, and in 1851 published his *Examen du système commercial connu sous le nom de système protecteur*. He played an important part in bringing about the conclusion of the Cobden commercial treaty between France and Great Britain in 1860. He became a member of the Senate in 1860.

Among his other works are: *Cours d'économie politique* (1842–50); *Essais de politique industrielle* (1843); *De la baisse probable d'or* (1859, translated into English by Cobden, *On the Probable Fall of the Value of Gold*, Manchester, 1859); *L'Expédition du Mexique* (1862); *Introduction aux rapports du jury international* (1868).

CHEVALIER, ULYSSE (1841–), French bibliographer, was born at Rambouillet on Feb. 24, 1841. He published a great number of documents relating to the history of Dauphiné, *e.g.*, the cartularies of the church and the town of Die (1868), of the abbey of St. André-le-Bas at Vienne (1869), of the abbey of Notre Dame at Bonnevaux in the diocese of Vienne (1889), of the abbey of St. Chaffre at Le Monestier (1884), the inventories and several collections of archives of the dauphins of Viennais, and a *Bibliothèque liturgique* in six volumes (1893–97), the third and fourth volumes of which constitute the *Repertorium hymnologicum*, containing more than 20,000 articles. But his principal work is the *Répertoire des sources historiques du moyen âge*.

The first part of the *Répertoire Bio-bibliographie* (1877–86; 2nd ed., 1905), contains the names of all the historical personages alive between the years 1 and 1500 who are mentioned in printed books, together with the precise indication of all the places where they are mentioned. The second part, *Topo-bibliographie* (1894–1903), contains not only the names of places mentioned in books on the history of the middle ages, but, in a general way, everything not included in the *Bio-bibliographie*. The *Répertoire* is one of the most important bibliographical monuments ever devoted to the study of mediaeval history.

CHEVALIER, literally, a horseman. In feudal times the term was equivalent to knight (*see* KNIGHTHOOD AND CHIVALRY), and later it was also employed in France for the cadets of noble families, where it is still used for the lowest rank of certain orders, as Chevalier of the Legion of Honour. The appellation of *Chevalier of St. George* was given to James Stuart, son of James II., the Old Pretender, and that of *The Young Chevalier* to Prince Charles Edward Stuart, the Young Pretender. The *Seigneur de Bayard* (*q.v.*) was known as the *Chevalier sans peur et sans reproche*.

CHEVAUX-DE-FRISE, a military obstacle, originating apparently in the Dutch War of Independence, and used to close the breach of a fortress, streets (French for "Friesland horses"; the Dutch *Vriesse ruyters*, "Frisian horsemen," and German *Spanische Reiter*, "Spanish horsemen"), etc. It was formerly often used in field operations as a defence against cavalry; hence the name, as the Dutch were weak in the mounted arm and had therefore to check the enemy's cavalry by an artificial obstacle. Chevaux-de-frise form an obstacle about 4 feet high, made of beams in which are fixed a number of spears, sword-blades, etc., with the points projecting outwards on all sides.

CHEVERUS, JEAN LEFEBVRE DE (1768–1836), French ecclesiastic, was born on Jan. 28, 1768, in Mayenne, France. He was made canon of the cathedral of Le Mans and began to act as vicar to his uncle in Mayenne, but owing to the Revolution he emigrated in 1792 to England, and thence in 1796 to Boston (Mass.). He spent several months in the Penobscot and Passamaquoddy missions and visited scattered Catholics. During the epidemic of yellow fever in 1798 he won great praise for his courage and charity; and his preaching attracted many

Protestants. In 1808 the pope made Boston a bishopric, suffragan to Baltimore, and Cheverus its bishop. Ill-health caused him to resign his bishopric, and in 1823, Louis XVIII. having insisted on his return to France, Cheverus became bishop of Montauban. He was made archbishop of Bordeaux in 1826; and in Feb. 1836, in accordance with the wish of Louis Philippe, he was made a cardinal, only five months before his death, which took place in Bordeaux on July 19, 1836.

See J. Huen-Dubourg, *Vie du cardinal de Cheverus* (Bordeaux, 1838); Eng. version by E. Stewart (Boston, 1839).

CHEVÉ SYSTEM. A method of teaching music to children in wide use in France. It is somewhat akin to the Tonic Sol-fa system, being based, like that, on the principle of a movable tonic, as opposed to the older "fixed Do" method, but employs numerals for the written signs of the different notes instead of the sol-fa syllables, although the latter are retained for vocal purposes. The system was invented by a French mathematical professor, Pierre Galin (1786-1821); developed and advocated by one of his followers, Aimé Paris (1798-1866), and perfected and popularized, after much controversy and opposition, by the latter's brother-in-law, Émile Joseph Maurice Chevé (1804-64).

CHEVET, in architecture, the entire eastern termination of a church choir (*q.v.*), a term used especially for churches with apses (*q.v.*); also an ambulatory (*q.v.*) from which a series of radiating chapels open. It is a distinctly French development, appearing in a highly organized form in many 12th century Romanesque churches; *e.g.*, Notre Dame du Port, Clermont-Ferrand and St. Paul, Issoire. It resulted from attempts to place as many subsidiary altars in chapels as possible, in close association with the high altar and the procession path around it. The development of the chevet produced many spaces of unusual shape whose vaulting was one of the great incentives toward the evolution of the ribbed and pointed vault; the chevet, therefore, plays an important part in the transition from Romanesque to

EXTERIOR VIEW OF LE MANS CATHEDRAL SHOWING ITS MAGNIFICENT FRENCH GOTHIC CHEVET OF THE 13TH CENTURY

Gothic. The radiating chapels are usually uneven in number, and the central one is frequently much larger than the others, dedicated to the Virgin Mary and known as the Lady-Chapel.

CHEVIOT, an incorporated village of Hamilton county, Ohio, U.S.A., 6m. W. by N. of Cincinnati, on the Chesapeake and Ohio railway. In 1910 the population was 1,930; in 1920, 4,108 (92% native white); and in 1930 it was 8,046 by the Federal census. It is primarily a residential suburb. The village was incorporated in 1901. It was named after the Cheviot hills by a Scotchman, who was the first settler, about 1800.

CHEVIOT CLOTH. A woollen fabric made originally from the wool of the well-known breed of Cheviot sheep, and now made from other types of wool. Cheviot wool possesses good spinning qualities, owing to the staple being of a fine, soft and pliable character. The true Cheviot type of fabric has a crispness of texture similar to serge cloth (*q.v.*) except that it is of a slightly rougher and heavier type. Cheviot fabric may be produced either from woollen or worsted yarns according to the character and texture or feel desired in the finished fabric. Some qualities are produced from cross-bred worsted yarns which are adapted for furnishing the crispness of texture which is one of the distinguishing characteristics of the true Cheviot type of fabric.

Cheviot suitings for sports wear are made from the harder spun worsted yarns, while some qualities are also made from Botany worsted. So-called Cheviot suitings of inferior quality contain an admixture of cotton, whilst other low-grade Cheviots are weighted with flocks. A stout, twilled, cotton fabric made from cotton warp and weft of coarse counts of yarn and woven with small dobby patterns or with fancy warp stripes, of brown or blue, with bleached weft, is also described as "Cheviot shirting."

(H. N.)

CHEVIOT HILLS, a range forming about 35 m. of the border between England and Scotland. The boundary generally follows the line of greatest elevation, but as the slope is more gradual southward than northward the larger part of the range is in Northumberland, England, and the lesser in Roxburghshire, Scotland. The axis runs from north-east to south-west, with a northward tendency at the eastern end, where the ridge culminates in the Cheviot, 2,676 ft. Its chief elevations from this point southward fall abruptly to 2,034 ft. in Windygate hill, and then more gradually to about 1,600 ft. above the pass, followed by a high road from Redesdale. Beyond this are Carter Fell (1,815 ft.) and Peel Fell (1,964 ft.), after which two lines of lesser elevation branch westward and southward to enclose Liddesdale. The rocks include Silurian, Old Red Sandstone (with lavas) and Carboniferous strata, and the hills are finely grouped, of conical and high-arched forms, and generally grass-covered. Their flanks are scored with deep narrow glens in every direction, carrying the headwaters of the Till, Coquet and North Tyne on the south, and tributaries of the Tweed on the north. The range is famous for a valuable breed of sheep. It was the scene of many episodes of border warfare, and its name is associated with the ballad of *Chevy Chase*. The main route into Scotland from England lies along the low coastal belt east of the Till; the Till itself provided another, and Redesdale a third. There are numerous ruins of castles and "peel towers" or forts on the English side in this district.

CHEVREUL, MICHEL EUGÈNE (1786-1889), French chemist, was born, on Aug. 31, 1786, in Angers, where his father was a physician. At about the age of 17 he went to Paris and entered L. N. Vauquelin's chemical laboratory, afterwards becoming his assistant at the natural history museum in the Jardin des Plantes. In 1813 he was appointed professor of chemistry at the Lycée Charlemagne, and subsequently undertook the directorship of the Gobelins tapestry works, where he carried out his researches on colour contrasts (*De la loi du contraste simultané des couleurs*, 1839). In 1826 he became a member of the Academy of Sciences, and in the same year was elected a foreign member of the Royal Society of London, whose Copley medal he was awarded in 1857. He succeeded his master, Vauquelin, as professor of organic chemistry at the natural history museum in 1830, and was its director (1860-79). He died in Paris on April 9, 1889, at the age of 103. Chevreul's name is best remembered for the classical researches he carried out on animal fats, published in 1823 (*Recherches sur les corps gras d'origine animale*). He determined the composition of stearin and olein, and isolated stearic and oleic acids. This work led to important improvements in the processes of soap and candle manufacture.

CHEVRON, any ornament formed of two slanting lines meeting at an angle. In heraldry it is a bent bar. It is also one of the most common distinguishing marks for military and naval uniforms, where it is placed on the sleeves and serves either as a

mark of honour or to indicate a special function. In architecture, the term is sometimes applied to the angle formed by the meeting rafters of a roof, but it is more commonly used for the purely decorative form. Chevrons joined together zigzag are one of the commonest of Romanesque geometric ornaments, especially in areas under Norman influence. It is a frequent decoration for arch mouldings and column shafts. The chevron appears early in primitive work and is found on pottery all over the world. It also occurs frequently in textiles, on Egyptian walls and ceilings, and in Aegean art as a column decoration (e.g., Tholos of Atreus at Mycenae, c. 1200 B.C.). (For military use see STRIPE.)

CHEVROTAIN or MOUSE-DEER, the representatives of the family *Tragulidae*. These tiny animals are not true deer, but constitute a special section of artiodactyles known as *Tragulina* (see ARTIODACTYLA). The typical genus *Tragulus*, which is Asiatic, contains the smallest representatives of the family, the animals having more of the general aspects and habits of rodents than of ruminants. A number of species are known, inhabiting the Malay Peninsula, the Indo-Malay Archipelago, Ceylon, and India. The second genus, *Dorcatherium*, is African, and distinguished by the feet being stouter and shorter, the outer toes better developed, and the two middle metacarpals not welded together. The only existing species, *D. aquaticum*, is rather larger than any of the Asiatic chevrotains, which it otherwise much resembles, but is said to frequent the banks of streams, and have much the habits of pigs. It is of a rich brown colour, spotted and striped with white. Remains of a species only differing in size (*D. crassum*) have been found in the Miocene deposits of France.

BY COURTESY OF THE LONDON ZOOLOGICAL SOCIETY
CHEVROTAIN, OR MOUSE DEER, A TINY ANIMAL ABOUT THE SIZE OF A RABBIT

CHEYENNE. This Algonkin tribe of the Plains, in Minnesota in the 17th century, drifted gradually westward through South Dakota to Wyoming and Colorado, and is now on reservations in Montana and Oklahoma. Their speech is much closer than either Blackfoot or Arapaho to the central Algonkin dialects, so that their divergence from the main body of the family is evidently relatively late. Since about 1850 the Sutaio, speaking a Cheyenne dialect, have been part of the tribe, though in 1804 they were still separate. The Cheyenne took a leading part in the Custer massacre of 1876. They were a typical Plains tribe—brave, warlike, non-agricultural, roving after the buffalo or for adventure; and they show the physical type at its best, being perhaps the tallest tribe in the area. The tribal fetish was a set of four sacred arrows. In 1922 the population was 3,200.

See Mooney, *Am. Anthr. Ass. Mem.* vol. i. (1907); G. B. Grinnell, *The Cheyenne Indians* (1923).

CHEYENNE (shí'én), the capital of Wyoming, U.S.A., and county seat of Laramie county; near the south-eastern corner of the State, on rolling plains east of the Laramie range, at an altitude of 6,058 ft. It is on Federal highways 30 (the Lincoln), 85 and 185; is served by the Burlington, the Colorado and Southern and the Union Pacific railways; and is an important point on the trans-continental air-mail route, with one of the best equipped air-ports in the country. The population in 1925 (State census) was 13,202, and in 1930 was 17,361 Federal census. The Union Pacific has extensive shops here, and there are meat-packing plants, brick-yards and various other industries. The city is a supply point for an extensive grazing and dry-farming area, and ships large quantities of cattle. The Frontier Days Celebration, held for five days each summer, is a picturesque festival at which Indians, cowboys and plainmen from Canada to Texas gather to give exhibitions of bronco-busting, steer-tying, Indian dances and other characteristic features of life in the old "wild west." Just north-west is Ft. Russell and its military manoeuvre reserve of 52,900 acres. Cheyenne was founded in 1867, when the Union

Pacific reached the spot. It was made the capital of the State and was incorporated in 1869.

CHEYNE, SIR WILLIAM WATSON, 1ST BART. (1852–), British surgeon, was born in the Shetland islands on Dec. 14, 1852, and was educated at Edinburgh, where he took his degrees in surgery and medicine in 1875. He also studied at Vienna, Paris and Strasbourg. In 1880 he was appointed to the chair of surgery at King's college, London, and from 1888 to 1890 was Hunterian professor of surgery at the royal college of surgeons. From 1900 to 1901 he was consulting surgeon to the South African forces. In 1914 he became consulting surgeon to the royal navy; he accompanied the British forces to Gallipoli, subsequently becoming surgeon-rear-admiral. He was created a baronet in 1908, and in 1916 received the K.C.M.G. In 1919 he was appointed lord lieutenant of Orkney and Shetland.

His published works include *Antiseptic Surgery* (1882); *The Antiseptic Treatment of Wounds* (1885); *Lectures on Suppuration and Septic Disease* (1889); *Objects and Limits of Operations for Cancer* (1896); *Manual of Surgical Treatment* (7 vols. 1899–1903); besides various papers on the treatment of wounds in war.

CHEYNE, THOMAS KELLY (1841–1915), English biblical scholar, was born in London on Sept. 18, 1841. Educated at Merchant Taylor's school and Worcester college, Oxford, he spent some time at Göttingen, where he heard Ewald lecture, and acquired an outlook on questions of biblical criticism then quite new in England. He made English readers familiar with the results of German biblical research, and laid the foundation of a new school of criticism in England. This was accomplished partly by his lectures, partly by a series of articles contributed to the 9th edition of the *Encyclopædia Britannica*, and to the *Academy*, where he was in charge of the biblical department, and by a series of independent works. After taking orders in 1864 he became vice-principal of St. Edmund hall, fellow of Balliol (1868–82), rector of Tendring, Essex (1880–85), Oriel professor of the interpretation of scripture at Oxford and canon of Rochester (1885–1908). He was appointed one of the board on the revision of the Old Testament (1884), and in that capacity acted with A. H. Sayce, William Robertson Smith and others. In his later years he adopted an extreme attitude, and alienated many scholars who had hitherto been in sympathy with him. He died at Oxford on Feb. 16, 1915. Among his more important works may be mentioned: *The Prophecies of Isaiah* (1880–81); *The Origin and Contents of the Psalter* (1891); *Jewish Life After the Exile* (1898); *The Reconciliation of Races and Religions* (1914).

CHÉZY, ANTOINE LÉONARD DE (1773–1832), French orientalist, was born at Neuilly on Jan. 15, 1773. He was the first occupant of the chair of Sanskrit in the Collège de France (1815), at that time the only chair of Sanskrit in Europe. Among his works were *Medjoun et Leila* (1807), from the Persian; *Yadjanadatta Badha* (1814) and *La Reconnaissance de Sacountala* (1830), from the Sanskrit; *L'Anthologie érotique d'Amrou* (1831), published under the pseudonym d'Apudry.

See the *Mémoires* of the Académie des Inscriptions (new series, vol. xii.), where there is a notice of Chézy by Silvestre de Sacy.

CHHATARPUR, an Indian state in the Bundelkhand agency of Central India. Area 1,130 sq.m.; pop. (1921) 166,549. The chief, whose hereditary title is raja, is a Rajput of the Ponwar clan, whose ancestor dispossessed the descendant of Chhatar Sal, the founder of Bundelkhand independence, towards the end of the 18th century. The state was guaranteed to Kunwar Sone Sah Ponwar in 1806. In 1854 it would have lapsed to the British Government for want of direct heirs, but was conferred on Jagat Raj as a special act of grace. The present chief has the title of Maharaja, and a salute of 11 guns. The town of Chhatarpur, which is named after Chhatar Sal, and contains his cenotaph, is 70 m. by road south-west of Banda. Pop. (1921) 10,142. There are manufactures of paper and coarse cutlery. The state also contains the British cantonment of Nowgong.

CHHATTISGARH, a division of the Central Provinces of India. Fifty years ago it was the most remote and isolated quarter of the Provinces, being shut off by the Maikal range from the Nagpur division on the west and by miles of hills and forests in the wilder States bordering it on the north, east and south.

It is a huge, undulating laterite plain, treeless except for the mango groves planted by generations of villagers round the village sites. It includes the three British districts of Raipur, Bilaspur and Drug, the last mentioned formed in 1906, after the Uriya district of Sambalpur and the five Uriya States which adjoin it had been presented to Bengal.

Outside the central plain are several feudatory States as well as large Zamindari properties. The five States received in exchange from Chota Nagpur, *i.e.*, Sirguja, Jashpur, Udaipur, Korea and Chang Bakhar, were added to the general political supervision of the commissioner of Chhattisgarh. Besides these States there are the true Chhattisgarh States of Raigarh, Sarangarh and Sakti on the east; Kawardha, Khairagarh, Nandgaon and Chhuikhadan on the west, and Kanker and Bastar on the south. The Mahanadi is the "Great River" which traverses Chhattisgarh on its way to the Bay of Bengal.

The formation of the country and the soil are distinct from all other parts of the Central Provinces. On the crests of the undulations the red laterite, locally known as "bhātā," emerges to the surface. In the depressions between these crests is black soil, gradually turning into brown and then into yellow as the ground rises. The laterite ridges are either barren or produce nothing but catch-crops of coarse rice when the rains are favourable. The depressions between are more fertile and often rich. The rich soils also are mainly under rice, but produce a second crop of pulses and oil seeds if the late rains are propitious. The western portion of the plain produces a fair amount of wheat and cold weather field crops.

Sir Richard Temple described Chhattisgarh as "the last stronghold of cheapness." Indeed, before 1860 rice was selling at 120 seers (240 lb.) to the rupee, and a labourer could feed himself on a shilling a month. In bad years there was scarcity, in good seasons a glut of grain, which rotted away for want of export facilities. This old-time isolation permitted a very ancient dynasty, the Hai Hai Bansis of Raipur and Ratanpur, to remain undisturbed for some seven centuries, but in 1743 Mahratta forces took the country without a blow. Aborigines occupied the hilly and jungly surroundings of the great plain. The open country is populated by Hindu castes and outcasts, of whom the Chamars, originally leatherworkers but now cultivators, in the 19th century under reforming leaders revolted against the oppression of the Brahmins and high caste Hindus.

The "Satnami" Chamars, as they are called, worshippers of the "true Name" (Satnam) are monotheists and total abstainers from liquor, some sections also prohibiting tobacco. They freely slaughter cattle and have other customs repugnant to Hindus, between whom and them there is hereditary hostility. There are also in Chhattisgarh many disciples of the saint Kabir (Kabirpanthis), but this sect is not peculiar to the division.

The great rice crop of Chhattisgarh was almost at the mercy of a droughty season, being broadcasted and unirrigated. It is a country with thousands of shallow village tanks unsuited for irrigation, wells are comparatively few and tank water is used indiscriminately for men and cattle, both for drinking and washing purposes. Wells are sparingly used, even when constructed at the expense of public funds, as the water is pronounced "tasteless." As a consequence, cholera is apt to be rife in the hot season and at its worst in times of drought and famine. The Bengal Nagpur Railway and Government Irrigation Works have worked wonders in improving the country, and education has made considerable though slow progress. The Chhattisgarh peasant (ryot) speaks a corrupt dialect of Hindi, akin to the dialect of Bagalkund.

Chhattisgarh has often been described as one of the granaries of India, but lack of irrigation, rough cultivation and excessive fragmentation of holdings, whereby one man holds numbers of tiny scattered rice plots instead of compact holding, has resulted in precarious and most uneconomical agriculture. Many storage tanks have been constructed by Government in the Raipur and Drug districts and a few in Bilaspur, and during the last fifteen years two major works, the Mahanadi and Tendula canals, have enabled very large areas to receive protection. Large works are

also under construction at Bilaspur, but the people are very slow in learning how to utilize irrigation to the best purpose. In time the agriculture should so improve that the "granary" of Chhattisgarh will justify that designation.

The division covers an area of 22,050 square miles and has a population of 3,381,687. In the decade of the great famine (1891-1901) it decreased by 9%, but by 1911 the lost ground had been recovered and the 1921 figures show a further small increase in spite of the great influenza epidemic of 1918. Satnami Chamars number nearly half a million. Hindus proper and Animists preponderate. Mohammedans are insignificant in numbers, being less than one and a half per cent of the whole population. (*See RAIPUR, BILASPUR.*) (R. H. C.)

CHHINDWARA, a town and district in British India, in the Nerbudda division of the Central Provinces. The town is situated on the Satpura plateau about 2,000 feet high. There are low hills in the neighbourhood and it is a pleasant station with a fairly temperate climate. The extension of the Satpura narrow gauge system of the Bengal Nagpur Railway from Seoni to Chhindwara was opened in 1905. Some years later the town was connected with Nagpur, and some small coal branches extended to the Pench valley coalfield. The town had a population of 8,626 in 1872, which had slightly increased to 9,736 in 1901; since the railways were constructed the population has grown, the figure in 1921 being 13,383.

It is just a market town with small local industries, and a trading centre for the open plateau lying mid-way between Nagpur on the south and Piparia on the G.I.P. Railway on the north. The town has the ordinary institutions of a district headquarters, and the Swedish Lutheran mission also has a station there.

District of Chhindwara.—The district has an area of 4,578 square miles and consists of three distinct types of country. On the north, bordering the Hoshungabad and Narsinghpur districts, are high hills, and rugged country constituting the *Jagirs* or feudal estates, held by old Gond chiefs, who were at one time marauders levying blackmail on travellers and raiding the open country on their borders. South of the *Jagirs* is the more level Satpura plateau extending from Betul on the west to Seoni on the east, and drained by the Pench and Kanhan rivers. The southern and eastern portions of the plateau are level, and include the fertile wheat plain of Chaurai. On the south again the country drops into the Nagpur plain, to which it geographically belongs. This is a rich cotton and juar (big millet) growing area, where the language is Marathi, and is the richest and most populous part of the district. On the south-east the plateau, here called the Lahmarpani, projects into the plain country, and this portion is noted for its breed of cattle. There are fairly extensive coalfields to the north of Chhindwara, connected by narrow gauge railway with Chhindwara town and by broad gauge line with Betul. In the south of the district, near the Nagpur border, are some valuable deposits of manganese.

The lowlands of the district are hot and the uplands have a temperate climate. The *Jagir* hills bordering the Mahadeo range just outside the district, rise to about 3,000 feet. These hills contain some sal forest. The Government forests on the southern slopes of the plateau and in the west of the district contain teak and other timber, but they are not very valuable.

The population of the district is 491,835. It suffered decline in the influenza decade, but shows a large increase on the 1872 figure of 316,000. About 75% are Hindus and most of the rest Gonds and other aboriginal tribes. Mohammedans are under 16,000. The literate population is small in the district as a whole, but the portion adjacent to Nagpur is the most advanced.

(R. H. C.)

CHIABRERA, GABRIELLO (1552-1638), Italian poet, was born at Savona on June 8, 1552. He studied philosophy at the Jesuits' college in Rome, and entered the household of a cardinal. He mixed in the literary society of his day, but presently was drawn into a quarrel which compelled him to leave Rome. He retired to Savona, where he read Pindar and Anacreon, and, no doubt, Ronsard. He determined to enrich Italian poetry with new forms, and his imitations from the classics include some

successful innovations in Italian verse, which were adopted by the lyrists of the next century. The mass of Chiabrera's work is very great, epics, pastorals, odes, lyrics, satires. But his best poetry is not to be found in his more ambitious works, but in the *canzonette* and *scherzi*, written to be set to music.

His autobiographical sketch is also extremely interesting. The simple old poet, with his adoration of Greek (when a thing pleased him greatly he was wont to talk of it as "Greek Verse"), his delight in journeys and sight-seeing, his dislike for literary talk save with intimates and equals, his vanities and vengeance, his pride in the memory of favours bestowed on him by popes and princes, his *infinita meraviglia* over Virgil's versification and metaphor, his fondness for masculine rhymes and blank verse, his quiet Christianity, is a figure deserving perhaps of more study than is likely to be bestowed on that "new world" of art which it was his glory to fancy his own, by discovery and by conquest.

BIBLIOGRAPHY.—Editions of Chiabrera's works are those of Rome (3 vols., 1718); Venice (4 vols., 1730); Leghorn (5 vols., 1781); Milan (3 vols., 1807); selection by F. Polydori (1865). See also G. Taccetta, *Gabriello Chiabrera e la sua produzione epica* (Catania, 1921); F. Neri, *Il Chiabrera e la Pléiade française* (Turin, 1920).

CHIANA (anc. CLANIS), a river which rises in the Apennines south of Arezzo, runs through the valley of Chiusi, and after receiving the Paglia just below Orvieto, falls into the Tiber after a course of 60 miles. In Roman times it often caused floods in the valley of Clusium. In the middle ages the whole of its valley from Arezzo to Chiusi was an uninhabitable swamp; but at the end of the 18th century the engineer, Count Fossombroni, moved the watershed some 25m. farther south, so its waters now flow partly into the Arno and partly into the Tiber.

CHIANG KAI-SHEK, otherwise **CHIANG CHUNG-CHENG** (1886–), Chinese General, a native of Ningpo, Province of Chekiang. At an early age he joined the Kuomintang, and in 1920 became Head of the Whampoa Military Academy, then lately founded under the advice of Michael Borodin unofficial agent of the Soviet Government. Under Borodin's ascendancy Sun Yat-sen and the Kuomintang leaders obtained control of the government of Canton and, with Soviet training and assistance, the Whampoa cadets developed into the mainstay of Sun's Army. At Sun's death in March, 1925, Canton City and neighbourhood were completely under the control of the Kuomintang Army, and in September Chiang secured the appointment of Commander-in-chief, with the Soviet General Galen as his unofficial Chief of Staff. By the end of the year, having defeated Chên Chiung-ming, he had brought Kwangtung and Kwangsi Provinces under the control of the Kuomintang "Executive Committee." This body, a development due to Borodin's remodelling of the party on Soviet lines, converted Sun's former semblance of government into the eventually successful Nationalist Government of China.

In 1926 Chiang made his amazing advance through Hunan to the Yangtze and established an administration at Wuchang. Thereafter a break with the extremists of the party caused the transfer of the seat of government to Nanking. Early in 1927 Chiang Kai-shek, restive under growing Soviet domination, embarked upon an anti-communist campaign throughout central and southern China. The result was the complete withdrawal of Borodin, Galen and the other Russian advisers. In August, 1927, he announced his retirement and later in the year visited Japan. In December he married Miss Mayling Soong, the sister-in-law of Sun Yat-sen, thus identifying himself with the constitutional element in the Kuomintang. Early in 1928 he resumed his post at the head of the Nanking Army, which bore its part in the northern advance, and final occupation of Peking. On Oct. 10, 1928, the 17th anniversary of the outbreak of the revolution, Chiang Kai-shek was inaugurated president of the Chinese National Government. The new constitution provided for a cabinet of ten ministers. (W. E. L.)

CHIAPAS, a Pacific coast State of southern Mexico on the Guatemalan frontier, bounded by the States of Tabasco on the north and Vera Cruz and Oaxaca on the west. Pop. (1895) 318,730; (1900) 360,799; (1921) 456,371, a large proportion of which are Indians; area, 27,222sq.m., largely forested. The Sierra

Madre crosses the southern part of the State parallel with the coast, separating the low, humid, forested districts on the frontier of Tabasco from the hot, drier, coastal plain on the Pacific. The mountain region includes a plateau of great fertility and temperate climate, which is one of the best parts of Mexico and contains the larger part of the population of the State; but isolation and lack of transportation facilities have retarded its development. The extension of the Pan-American railway across the State, from San Geronimo, on the Tehuantepec National line, to the Guatemalan frontier, is calculated to improve the industrial and social conditions of the people. The principal industries are agriculture, which is very backward, stock-raising, timber-cutting, fruit-farming and salt-making. Coffee-planting is a new industry on the Pacific slope of the Sierra Madre at elevations of 2,000 to 4,000ft., and has met with considerable success. Rubber plantations have also been laid out, principally by American companies. The exports include mahogany, dye-woods, cattle, hides, coffee, rubber, fruit and salt. The mineral resources include gold, silver, copper and petroleum, but no mines were in operation in 1926. The capital, Tuxtla Gutierrez (pop. 9,395 in 1900; 22,120 in 1920), is on the plateau, 3½m. from the Rio Sabinas, and 138m. N.E. of the Pacific port of Tonala. The former capital, San Cristobal (pop. about 5,000 in 1895 and 13,562 in 1921), about 40m. E. of Tuxtla, is an interesting old town and the seat of the bishopric of Chiapas, founded in 1525 and made famous through its associations with Las Casas. Tapachula (pop. in 1895, 6,775, and 12,180 in 1921), the capital of the department of Soconusco, 18m. from the Guatemalan frontier, is a rising commercial town of the new coffee district. It is 24m. inland from the small port of San Benito, is 559ft. above sea-level, and has a healthful climate. Other prominent towns are Comitán, or Comitlan, on the Rio Grijalva about 40m. S.E. of San Cristobal, Pichucalco, Tenejapa, Cintalapa, La Concordia, San Carlos and Ococingo.

CHIAROSCURO, the disposition of light and shade in a painting (Ital. *chiaro*, light, *oscuro* shade); the term is applied to an early method of printing wood-engravings from several blocks, and also to a picture in black and white, or brown and white only. It has also come to mean the atmospheric effect produced by the handling of high lights and shadows.

CHIAVARI, a town near the mouth of the Entella, Liguria, Italy, province of Genoa, 24 m. S.E. by rail from Genoa. Pop. (1921) 12,501, 14,739 (commune). It is in a fertile plain surrounded by mountains except on the south-west where it comes down to the sea. It trades in farm products, and makes lace, light wicker-seated bentwood chairs and silk.

CHIAVENNA (anc. *Clavenna*), a town of Lombardy, Italy, in the province of Sondrio, 17m. by rail north of Colico, which lies at the north end of the Lake of Como. Pop. (1921) 3,201 (town); 4,699 (commune). It is on the right bank of the Mera, at the mouth of the Val Bregaglia, through which the road to the Maloja pass and the Engadine runs to the east. This line was followed by a Roman road, which took the Julier route to Coire (anc. *Curia*). The Splügen route, also used by the Romans, runs north from Chiavenna to Coire: the modern road was constructed by the Austrians in 1819–21. Chiavenna's ruined castle was the seat of the counts who ruled the valley from the time of the Goths till 1194, when the district was handed over to the bishops of Coire. In the 14th century the Visconti, as masters of the Valtellina, bought the "county" of Chiavenna from the bishop of Coire; but it was taken by the canton of the Grisons in 1525, and the castle dismantled. In 1797 Chiavenna became part of the Cisalpine republic, and thenceforward followed the fortunes of Lombardy. Chiavenna has cotton factories and breweries, and is a depot for the wine of the district owing to the coolness of the caves which are used as cellars.

CHIBCHAN, an important linguistic stock of South American and Central American Indians. The tribes to be included within this stock and its precise geographic limits are still open to discussion. Beginning with the Ulvan (*q.v.*) tribes along the Honduras-Nicaragua border southward and eastward through Nicaragua, Costa Rica and Panama, the larger proportion of all the tribes belonged to Chibchan stock. In Colombia they probably

held most of the drainage basins of the Magdalena and Cauca rivers. The region of the Cordillera Central, between these streams, was, however, held by tribes classed as Paniquitan (*q.v.*), who are regarded by some as constituting a distinct stock. Rivet would include as Chibchan also the Barbacoan (*q.v.*) and Coconucan (*q.v.*) tribes farther south, extending as far as the equator in western Ecuador. There has been considerable difference of opinion as to whether the direction of movement of the stock has been southward into South America or from the southern continent into North America. The more recent opinion seems to favor the former view, but the question cannot by any means be regarded as settled. The stock has received its name from the Chibchas (*q.v.*), the most important tribe of the stock at the time of the Spanish conquest.

See H. Beuchat and P. Rivet, *Affinités des langues du sud de la Colombie et du nord de l'Equateur* (Museum, 1910, vol. xi.); W. Lehmann, *Zentral Amerika* (Berlin, 1920).

CHIBCHAS, a small group of tribes of South American Indians, occupying at the time of the Spanish conquest the high valleys in the vicinity of Bogota and Tunja in Colombia. In their culture the Chibchas and other related tribes in the vicinity ranked next to that developed by the Inca and their predecessors in Peru and Bolivia. They were, however, on a distinctly lower level, for although a sedentary, agricultural folk, skilful weavers and artificers in gold, they had little copper and no bronze. They were also much inferior in pottery making, had no knowledge of stone or sun-dried brick construction, and had no means of record, such as the Peruvian quipu. Just prior to the advent of the Spanish, the Zipa or chief of the Chibchas at Bogota had been successful in extending his political control over several of the tribes further north, and seems to have initiated a movement which, but for the Spanish conquest, might have paralleled the military expansion of the Aztecs in Mexico. Like the latter, the Chibchas employed human sacrifice in their religious ceremonies. In one of these, the chief or "king" was smeared with a sticky substance and then powdered with gold dust, which was subsequently washed off by bathing in a sacred lake. It was this practice which, at least in part, gave rise to the legend of "El Dorado." The dead were buried in well-graves which sometimes attained a depth of 30 or 40 ft.

See L. F. de Piedrahita, *Historia General de las Conquistas del Nuevo Reyno de Granada* (Verdussum, 1688); P. Simon, *Noticias Historiales*, etc. (Bogota, 1882); P. de Aguado, *Historia de Santa Marta y Nuevo Reino de Granada* (new edition, Madrid, 1916).

CHIBOUQUE or **CHIBOUK**, a long Turkish pipe (Fr. form of the Turk. *chibūk*, a stick), often ornamented with precious stones.

CHIC, in French artistic slang, the quality of facile but superficial brilliance in a work of art, or an effect produced by imagination without reference to a model; in its general sense, it connotes smartness in dress. The use of the word in France dates from Louis XIV's reign when it denoted a lawyer who was master of "chicane" or legal trickery.

CHICA, a fermented liquor resembling beet made by the natives of South America from Indian corn; also an orange-red pigment or dye stuff obtained from the leaves of *Bignonia chica* by the Orinoco Indians.

CHICACOLE, a town of British India in the Ganjam district of Madras, situated on the right bank of the river Languliya, here crossed by a bridge, 4 m. from the sea. Pop. (1921) 16,298. Under Mohammedan rule it was the capital of one of the Northern Circars, and afterwards of a British district. Several old mosques remain. The town was formerly famous for its muslins. The roadstead and lighthouse of Calingapatam are about 16 m. to the north, and the Bengal-Nagpur east coast railway has a station 8 m. inland.

CHICAGO, a city, a port of entry and the county seat of Cook county, Illinois, the second city of the United States in population, commerce and manufacture; pop. (1900) 1,698,575; (1910) 2,185,283; (1920) 2,701,705; (1930) 3,376,438. The increase in the decade, 1920-30, partly as a result of annexations, was 674,733, the largest gross gain in the history of the city. The

percentage of increase was 25.0, the smallest, except for the decade 1910-20, in the city's history. The population of the metropolitan district of Chicago, embracing suburbs of the city both in Illinois and Indiana, but excluding adjacent communities in Wisconsin, was estimated by the bureau of the census at 3,986,331 on Jan. 1, 1925.

As is the case with most American cities, the growth of the population of Chicago has decreased relatively to the growth

LOOKING SOUTH ON MICHIGAN BOULEVARD FROM THE LINK BRIDGE. TO THE LEFT, THE NEW 333 N. MICHIGAN AVENUE BUILDING; ACROSS FROM IT, THE LONDON GUARANTEE BUILDING

of the outlying communities of its metropolitan area. The rate of regional growth about the city seems to be increasing as the rate of strictly urban growth declines, largely because of the extension of motor traffic and hard-surfaced highways. The percentage of increase in the period 1910-20 was less than that of any other decade, and the percentage for the next decade, 1920-30, while somewhat larger, was the next smallest. Chicago is situated at the south-west corner of Lake Michigan (lat. 41° 50' N., long. 87° 38' W.), about 913 m. distant by railway from New York, 912 m. from New Orleans, 2,265 m. from Los Angeles and 2,330 m. from Seattle. The climate is very changeable and is much affected by the lake; changes of more than 30° in temperature within 24 hours are not rare, and changes of 20° are common.

The city is the greatest railway centre of the United States; and was for several decades practically the only commercial outlet of the great agricultural region of the northern Mississippi

valley. Trunk-lines reach east to Montreal, Boston, New York, Philadelphia, Baltimore (the nearest point on the Atlantic coast, 854m.); south to Charleston, Savannah, Florida, Mobile, New Orleans, Port Arthur and Galveston; west to the Pacific at Los Angeles, San Francisco, Seattle and Vancouver, and to most of these by a variety of routes. Thirty-two trunk-lines operated by 22 railway companies enter the Chicago terminal district. In this terminal system about 4½% of the total freight tonnage of the United States is loaded and 6¼% unloaded annually. Chicago is also the greatest Canadian railway centre from a traffic standpoint. The Canadian National lines and the Canadian Pacific enter it through subsidiaries. Chicago's passenger terminal situation, like her intramural rail transit problem, is being altered to fit the great city, which grew up around the original railheads and then passed miles beyond them. In 1911 the passenger station of the Chicago and Northwestern railway, a dignified structure costing \$20,000,000, was opened for service. The railways using the union station directly south of this terminal—the Pennsylvania, the Burlington, the Chicago and Alton and the St. Paul—completed in 1925 their terminal at a cost of \$75,000,000. With the construction of a great postal terminal building near by, this completed the rearrangement of the terminals of the six railroads on the west side of the Chicago river. But the far more numerous railways entering four passenger terminals on the south side, have spent years working out a plan for consolidation and rearrangement among themselves. Strong sentiment exists for the consolidation of all these terminals in the new Illinois Central station to be erected at 12th street, but any plan adopted is to be worked out in connection with the straightening of the south branch of the Chicago river, the opening of more north and south streets, electrification and the building of streets and business structures over the electrified yards and terminal tracks lying south of the business district. The first railway electrification was completed July 21, 1926, when the Illinois Central railway opened its electrified suburban passenger service over the 30m. from Matteson, Ill., to Randolph street at a total cost of \$40,000,000.

With its suburbs within the area of the Chicago railway terminal district, Chicago occupies a crescent-shaped area, the concave side of which is the shore of Lake Michigan. This district is approximately 1,700 sq.m. in extent, about the size of the State of Rhode Island, and lies along the lake shore for about 55m. (the incorporated city proper for 26.5m.). The city proper had an area of 208.61 sq.m. in 1927. It spreads loosely and irregularly backward from the lake over a shallow alluvial basin, which is rimmed to the west by a low moraine water-parting that separates the drainage of the lake from that of the Mississippi valley. The city site has been built up out of the Lake Chicago of glacial times, which exceeded in size Lake Michigan. Three lakes—Calumet, 3,122ac.; Hyde; and part of Wolf—with a water-surface of some 4,100ac., lie within the municipal limits. The original elevation of what is now the business heart of the city was only about 7ft. above the lake, but the level was greatly raised—in some places more than 10ft.—over a large area, between 1855 and 1860. The west side, especially the north-west near Humboldt park, is much higher (highest point, 75ft.). A narrow inlet from the lake, the Chicago river, runs west from its shore about a mile, dividing then into a north and south branch, which run respectively to the north-west and the south-west, thus cutting the city into three divisions known as the north, the west and the south "sides," which are united by three car-tunnels beneath the river as well as by the bridges across it. The river no longer empties into Lake Michigan since the completion of the drainage canal. Its commercial importance is yet very great, but with the change in the character of lake traffic it is diminishing, and this stream and harbour upon which Chicago's history and greatness were based are now looked upon primarily as an obstruction to urban street traffic. Agitation for the abolition of the river as a shipway and for the substitution of fixed bridges for the draw, lift and bascule types which now span it, is active. Ship traffic on the lake has become principally a matter of the transport of bulk cargoes of iron ore, coal, coke and limestone direct from mine rail terminals

to the great iron, steel and cement plants with their own docks on the south shore of Lake Michigan. Traffic has shifted to the ports on the southern extremities of the city, Calumet, Indiana Harbour, etc.; and steamers formerly docking in the river call at the municipal pier or dock in the outer harbour. Some lake cargo destined for Chicago is landed at Milwaukee and comes in by rail.

Upon the completion of the Illinois waterway, connecting Chicago, through the Illinois and Mississippi rivers, with New Orleans by a barge route of 9ft. draft, the Chicago river would become an important link for through water traffic, but it is proposed to obviate this by cutting a direct canal to connect the south lake harbour with the drainage canal, which will constitute a link of the waterway. The improvement of the outer harbour by the Federal Government was begun in 1833. Great breakwaters protect the river mouth from the silting shore currents of the lake and afford secure shelter in an outer roadstead from its storms, and there is a smaller inner basin (about 450ac., 16ft. depth) as well. The river itself has about 15m. of navigable channel, in part lined with docks. Its channel has been repeatedly deepened and, especially since 1896, after its control as a navigable stream passed (1890) to the Federal Government, widened and straightened by the removal of jutting building constructions along its shores. Grain elevators of enormous size, coal-yards and grimy warehouses crowd close upon it. In 1927 the south bank of the river from the Michigan avenue bridge to Lake street, which is the northern boundary of the Loop business district, was completely denuded of abutting buildings by the opening of the two-level Wacker drive, a broad boulevard upon a gigantic concrete structure occupying the space of former blocks of buildings and streets. This construction, which cost about \$28,000,000, and which connects with the new Michigan avenue bridge and the two-level boulevards approaching it, is the first item of a programme designed to convert the entire south and east banks of the river into broad traffic arteries. Farther south, according to an agreement of the railways, property owners and the city, the south branch of the river which curves to the east for about a mile of its length is to be moved westward for a maximum distance of a quarter of a mile, to allow of the construction of four wide streets leading from the south into the Loop district. This plan, which is also an aid to the reconstruction and electrification of the south side railways, is estimated to cost \$8,000,000, with an ultimate expenditure of \$162,000,000 by the railroads affected, in the reconstruction of the south side railway terminals.

The plan of the city was originally regular, i.e., rigidly rectangular, and the original streets were wide according to the standards of the days of horse-drawn traffic. The original plan has been altered by the construction of a great number of boulevards in the outer areas, which in connection with the growth of the park system and the construction of driveways in the parks have provided numbers of diagonal traffic arteries. The recovery of land from the lake and the construction of a great parkway system along the lake front have also led to the belting of the down town areas on the east with a number of north and south boulevards not in keeping with the original plan of the city. The initiation and completion of these projects have been so rapid and the number of new plans in various stages of execution is so great that the older parts of Chicago have been profoundly altered, especially since the beginning of the great building boom in 1922.

Rapid transit by rail has not kept pace with these improvements in streets. One result of this is that a number of outlying business, hotel and apartment centres have grown up, which are beginning in the aggregate to rival the Loop, the former business, financial, theatrical and hotel centre. Chicago has begun to develop into a series of urban centres rather than a centralized city on the usual American model. Notwithstanding the growth of these outlying centres, however, the construction of great buildings within the Loop from 1922 to 1928 proceeded at a pace never approached before, while the opening of Wacker drive and the Michigan avenue bridge enabled the business district to break out of the narrow confines of the former Loop district—the 1.5 sq.m. lying between the lake, the main Chicago river and the south branch of

TOWERS OF CHICAGO

Etching by Anton Schutz, showing the Wrigley building and Tribune tower, two of Chicago's finest architectural achievements, as seen from Wacker Drive Plaza, at the south end of "link" bridge. These two buildings, one surmounted by a white terra-cotta clock tower, the other of grey stone, with Gothic flying buttresses, are visible from Lake Michigan and many parts of the city

PHOTOGRAPHS, (1) UNDERWOOD AND UNDERWOOD, (2) AERIAL PHOTOGRAPHIC SERVICE, INC.

THE CENTRAL BUSINESS SECTION OF CHICAGO

1. A section of the central business district. At the left is the tower of the new Morrison hotel, 635 feet high. The flat-roofed buildings in the extreme right foreground, are large department stores at the intersection of Madison and State streets, a shopping district locally known as the "world's busiest corner"
2. Aerial view of the "loop" and near north side, looking south from the lake shore. Grant park, Chicago's "front yard," is in the left background, bounded on the right by Michigan avenue, beyond which rise the towers of the city. The main channel of the Chicago river, which divides the city into a north and south side, is seen near its point of junction with Lake Michigan

the river. This northward advance of the business district was accompanied by the construction of numbers of the tower type of office building. This forest of bold and graceful towers has relieved the former drab monotony of down town Chicago. The construction of so many great office buildings and hotels in the down town district has made the problem of street congestion increasingly acute despite the enormous expenditures upon new boulevards. Hope for any material relief from the construction of the freight tunnels vanished with the advent of the popular priced automobile, and the capacity of these underground freight arteries is such that they can handle only a trifling percentage of the movement of goods in the district. A belt of "bad lands"—deteriorated residence, shop and factory property, surrounds the business district except on the north-east. Here a great section crowded with expensive family and apartment hotels has grown up on the lands reclaimed from the lake in the section called "Streeterville"—named from a belligerent old squatter, who long claimed title to these accretions, because his schooner had stranded on that shore. Chicago's architectural achievements are yet blighted by the use of soft coal which after a time smears a drab colour on the finest structures. Vigorous efforts to combat this nuisance have had small results. Yet the skyline, the immensity of the traffic movement and the massiveness of its central district give the city a distinct tone, found nowhere else.

The unstable soil of sand, clay and boulders that underlies the city is unfavourable to tall constructions, and necessitates extraordinary attention to foundations. The bed-rock lies, on an average, 50ft. below the level of the lake (in places more than 100). The foundations are often sunk to the rock in caissons, the buildings resting on monster columns of concrete and steel. In other cases great "pads" of the same materials, resting or "floating" upon the clay, sustain and distribute the weight of the building. Buildings notable for their architectural boldness and the beauty which has resulted from the conversion of the economics of the tall structure to aesthetic purposes are the Chicago temple, a spire above an office pile, 214ft. in height, cost \$5,000,000; the Tribune tower, distinguished for its flying buttresses, 462ft., \$7,000,000; the Pure Oil building, 543ft., cost \$11,704,000; the Wrigley building, 398ft. to the top of its campanile tower, cost \$6,500,000; the Straus building, 475ft., cost \$18,000,000; the Mather tower, 519ft., cost \$2,100,000. Distinguished more for massiveness than architectural appeal are the new Palmer house, 260ft., cost \$17,000,000; the Stevens Hotel, 340ft., cost \$30,000,000; the Federal Reserve, 260ft., cost \$7,000,000; the Illinois Merchants Trust, 260ft., cost \$18,000,000; the Furniture mart, 474ft., cost \$14,000,000; the Morrison hotel, 635ft., cost \$16,000,000. These buildings were among the number of huge structures erected during the great revival of building activities which followed the World War. Older buildings associated with the city's history or notable architectural triumphs of their day are the Auditorium containing a hotel and a theatre which seats 5,000, long the home of Grand opera, the Masonic temple, the Monadnock, the People's Gas building, the La Salle, Blackstone and Sherman hotels and the Marquette building. There are a number of enormous retail stores. The largest, and one of the finest in the world, is that of Marshall Field and Co. The wholesale building of the same firm is the work of H. H. Richardson, and is considered one of his best, and one of the most admirable examples of American commercial buildings. The city hall and county court house (cost \$4,500,000) is an enormous double building in a free French Renaissance style, with columned façades. The Federal building (finished in 1905; cost, \$4,750,000) is a massive edifice (a low rectangle surmounted by a higher inner cross and crowned with a dome). The public library (1893-97, \$2,125,000), constructed of dark granite and limestone, with rich interior decorations of varied frescoes, mosaics, ornamental bronze and iron work, and mottoes, is one of the handsomest libraries of the country. The Chicago Art Institute (1892-93; Italian Renaissance), the Chicago Orchestra building (1904), and the Commercial National bank, are also noteworthy. The Field museum completed in 1920 at a cost of \$6,000,000 is a white marble structure in Ionic style, 350ft. wide and 700ft. long. The municipal pier, completed in 1915, projects 3,000ft. into

Lake Michigan, north of the mouth of the Chicago river and combines the functions of an enormous dock and a playground; the outer portion, 660ft. long, is a three-decked structure devoted to amusement and recreation purposes. The movement of wealthier residents to surrounding communities has left the city proper without any notable street of private homes, although many of the older boulevards are fringed by dignified houses. The physical growth of Chicago in the 18-year period prior to July, 1927, was guided by a definite plan laid down by the Chicago plan commission, created by the city council during the administration of Mayor Fred A. Busse. The plan had its genesis in a report of Daniel H. Burnham and was submitted by the Commercial club to the city and adopted as an enduring policy. It took cognizance of the natural features of Chicago's site and environs and proposed the gradual adaptation of the city then existing, and the city as it grew, to the best uses of its natural setting—from a commercial, industrial, social and cultural standpoint. Eighteen of the major projects of the Chicago plan have already been realized. In its original entirety the plan will probably be completed in 1950, but it has been constantly modified and expanded to keep pace with new conditions and problems. Railroads, public utility companies and industrialists have co-operated to carry out its designs. The Chicago plan has demonstrated that the most intensive modern industrialism and commercial activity can be profitably harmonized with beauty, social welfare and ample recreational and cultural centres for the people of a metropolitan city.

Public Works and Communications.—Local transit is provided for by the suburban service of the railways, elevated electric roads, and a system of electric surface cars. Two great public works demand notice: the water system and the drainage canal. Water is pumped from Lake Michigan through several tunnels connecting with cribs located from 2 to 5m. from shore. The cribs are heavy structures of timber and iron loaded with stone and enclosing the in-take cylinders, which join with the tunnels well below the bottom of the lake. The first tunnel was completed in 1867. They now form a labyrinth 72m. in extent under the lake and city. The average amount of water pumped per day is 877,811,400 gallons. Because of pollution of lake water from the wastes of Indiana cities, not participating in the drainage system of the Chicago sanitary district, this water has been chlorinated at the in-takes. The wastes of the city—street washings, building sewage, the offal of slaughter-houses, and wastes of distilleries and rendering houses—were originally turned into the lake, but before 1870 it was discovered that the range of impurity extended a mile into the lake, half-way to the water crib, and it became evident that the lake could not be indefinitely contaminated. The Illinois and Michigan canal was once thought to have solved the difficulty. It is connected with the main (southern) branch of the Chicago river, 5m. from its mouth and with the Illinois river at La Salle, and is the natural successor in the evolution of transportation of the old Chicago portage, ½m. in length, between the Chicago river and the headwaters of the Kankakee. It was so deepened as to draw water out from the lake, whose waters thus flowed toward the Gulf of Mexico, but it proved inadequate for the disposal of sewage. A solution of the problem was imperative by 1876, but almost all the wastes of the city continued nevertheless to be poured into the lake. In 1890 a sanitary district, including part of the city and certain suburban areas to be affected, was organized, and preparations made for building a greater canal that should do effectively the work it was once thought the old canal could do. The new drainage canal, one of the greatest sanitary works of the world, constructed between 1892 and 1900 under the control of the trustees of the sanitary district of Chicago, joins the south branch of the Chicago with the Des Plaines river, and so with the Illinois and Mississippi. The canal, or sewer, is flushed with water from Lake Michigan, and its waters are pure within a flow of 150 miles. Its capacity, which was not at first fully utilized, is 600,000 cu.ft. per minute, sufficient to renew entirely the water of the Chicago river daily. A system of intercepting sewers to withdraw drainage from the lake was begun in 1898; and the construction of a canal to drain the Calumet region was begun in 1910. The drainage canal is the backbone of a great system of

feed water lateral canals and underground sewers. The drainage canal became the nucleus of the lakes to the Gulf waterway, under construction by the State of Illinois to connect the drainage canal with the Illinois river, the Federal Government undertaking the improvement of the rivers to the gulf. The canal also made possible the development of hydro-electric power at Lockport, which is used by the sanitary district and for street lighting in Chicago. The total cost of construction of the works of the sanitary district up to 1924 was \$94,371,038. However, this great investment by Chicago appears to have been only a beginning. The lowering of lake levels which resulted brought protests and litigation from other lake cities. Shipping interests blamed the drainage canal for the lowering of lake levels and the shoaling of port and dock channels. The sanitary district denied responsibility for more than 6in. of the fall in the levels of Lakes Michigan, Huron and Erie, and offered to construct compensating weirs to retain levels in the St. Clair river, connecting Lakes Huron and Erie, and in the Niagara river. Litigation against the sanitary district by the other lake States was defended in the United States Supreme Court by the State of Illinois, assisted by other States of the Mississippi valley interested in maintaining the diversion of lake water into the Mississippi drainage system in aid of navigation. On Jan. 5, 1925, the United States Supreme Court held that jurisdiction over the amount of water which the sanitary district might divert rested with the secretary of war. On March 3, 1925, that official granted the district a five year permit to withdraw 8,500 cu.ft. per second. This permit however was conditioned upon performance by the sanitary district of tasks, which may eventually cost hundreds of millions of dollars. Already vast sums have been expended upon plants for the chemical treatment of sewage rather than its dilution—and in this work Chicago is far ahead of other American cities. Total appropriations for administration, maintenance and further construction by the sanitary district for 1926 were \$34,180,824.

Chicago was one of the earliest centres of aerial transport in the United States, the original night air-mail service over an illuminated route joining Chicago and New York. In 1927 the city was the centre of approximately 7,000m. of regularly operated mail, express and passenger air lines, and a municipal air-port covering 320ac. was opened that year at Cicero avenue and 63rd street.

Atrophy of the city's internal traction and elevated systems during the period 1907-27 was partially compensated for by the establishment of numerous motor bus lines on the boulevards and parkways, and by the extension and modernization of electric railways in the outlying regions. Numerous bus lines connecting Chicago with other towns and cities have come into competition with the railways. Another great improvement was begun in 1901 by a private telephone company. This is an elaborate system of freight subways, more than 65m. of which, underlying the entire business district, had been constructed before 1909. It is the only subway system in the world that seeks to clear the streets by the lessening of trucking, in place of devoting itself to the transportation of passengers. Direct connection is made with the freight stations of all railways and the basements of important business buildings, and coal, building materials, ashes and garbage, railway luggage, heavy mail and other kinds of heavy freight are expeditiously removed and delivered. Telegraph and telephone wires are carried through the tunnel, and can be readily repaired. The subway was opened for partial operation in 1905. However, street traffic growth has been so great and the capacity of the tunnels so small, that the 120 locomotives and 3,000 cars operated in the tunnels handle less than 10% of railway freight loaded or unloaded in the business district.

Parks.—The park system may be said to have been begun in 1869, and in 1870 aggregated 1,887 acres. Chicago then acquired the name of the "Garden City," still emblazoned on the municipal coat of arms. But other cities later passed her, and in 1904 she ranked only 32nd among American cities of over 100,000 population in *per capita* holdings of park acreage. In 1927 the area of the city's parks was 5,912ac. but this is being rapidly extended all along the lake front by the reclamation of land from the lake

for parks, bathing beaches and another municipal air-port adjacent to the business district. Eventually the entire lake front, except for the relatively small areas devoted to port purposes, will be a line of parks available for recreational purposes, in addition to the islands to be created as a site for the 1933 Centennial exposition. In addition to the city park system, the Cook county forest preserves, a broad belt of wooded lands, 30,850ac. in extent, acquired at a cost of \$14,000,000, form a belt north, south and west of the city. The recreational value of this great playground is attested by a census of visitors in 1927 which totalled 5,500,000. In the same year 4,582,000 persons bathed at the city's supervised bathing beaches and 3,700,000 children were counted at the city's playgrounds. The large and small parks in 1928 numbered 211. There were 71 bathing beaches and public pools, 25 free public golf courses and 73 public playgrounds. The park in each district, usually located near a school, is almost all-inclusive in its provision for all comers, from babyhood to maturity, and is open all day. There are sand gardens and wading ponds and swings and day nurseries, gymnasiums, athletic fields, swimming pools and baths, reading-rooms—generally with branches of the city library—lunch counters, civic club rooms, frequent music, assembly halls for theatricals, lectures, concerts or meetings, penny savings banks, and in the winter skating ponds.

The older parks include several of great size and beauty. Lincoln park, on the lake shore of the north side, has been much enlarged by an addition reclaimed from the lake. It has fine monuments, conservatories, a zoological garden and the collections of the Academy of Sciences. Jackson park, on the lake shore of the south side, was the main site of the World's Columbian Exposition of 1893. It is joined with Washington park by the Midway Plaisance, a wide boulevard. Along the Midway are the greystone buildings of the University of Chicago, and of its (Blaine) School of Education. On the west side are three large parks—Douglas, Garfield (with a fine conservatory) and Humboldt, which has a remarkable rose garden, and in the extreme south side several others, including Calumet, by the lake side, and Marquette. Jackson boulevard, Western avenue boulevard and Marshall boulevard join the south and the west park systems. The shore of the north side is quite free, and beginning a short distance above the river is skirted for almost 30m. by Lake Shore drive, Lincoln park and Sheridan Road. In Grant park is the building of the Art Institute, the Shedd aquarium, the Field Museum of Natural History and Soldier field, a great stadium devoted to sports and pageants, with a seating capacity of 145,000. About two-thirds of the city's frontage on the lake was composed of parks or boulevards in 1927. The inner boulevards and the drives through the lake front parks are parked ways ranging from 150 to 300ft. in width.

Art.—A city art commission approves all works of art before they become the property of the city, and at the request of the mayor acts in various ways for the city's aesthetic betterment. The Architectural club labours for the same end. A municipal art league (organized in 1890) has done good work in arousing civic pride; it has undertaken, among other things, campaigns against bill-board advertisements and against the smoke nuisance. The Art Institute of Chicago contains valuable collections of paintings, reproductions of bronzes and sculpture, architectural casts and other objects of art. Connected with it is the largest and most comprehensive art school of the country—including classes in newspaper illustration and a normal school for the training of teachers of drawing in the public schools. The courses in architecture are given with the co-operation of the Armour Institute of Technology. The Kenneth Sawyer Goodman memorial theatre, associated with the institute, opened its first season of endowed repertory in 1925. A school of the drama is conducted in connection with the theatre. The trustees of the Art Institute administer the Ferguson monument fund, left by the will of Benjamin Franklin Ferguson, to be used for the erection of statuary and monuments in Chicago. Among others, two notable pieces by Lorado Taft have been purchased; "The Fountain of the Great Lakes" stands just to the south of the Art Institute; "The Fountain of Time," at the head of the Midway, between Washington

and Jackson parks. The Field museum of natural history, established (1894) largely by Marshall Field, is mainly devoted to anthropology and natural history. The nucleus of its great collection was formed by various exhibits of the Columbian Exposition which were presented to it. Its collections of American ethnology, of exceptional richness and value, are constantly augmented by research expeditions.

The Chicago Civic Opera company was organized in 1910 under the name of the Chicago Grand Opera company, re-organized in 1915 as the Chicago Opera association, and again in 1921 under its present title. Operating under a heavy deficit, it is supported by subscription. The Chicago Symphony orchestra was founded in 1891 by Theodore Thomas, who conducted it until his death on Jan. 4, 1905. He was succeeded by Frederick A. Stock. Late in 1904 Orchestra hall was built from money raised by popular subscription, and this building has made the orchestra self-supporting. The orchestra plays from 110 to 120 concerts each season. In addition Chicago has dozens of lesser orchestras, choral organizations, and many musical schools of large membership. The oldest choral organization is the Apollo Musical club which dates back before the great fire of 1871. Harrison M. Wild has been its conductor for over half a century.

Libraries.—At the head of the libraries of the city stands the public library established in 1872, the nucleus of which was a collection of books from England made by Thomas Hughes, author of *Tom Brown's School Days*, after the great Chicago fire of 1871, a collection to which Queen Victoria and other contemporary British notables made contributions. The library was opened in 1874. At the close of 1926 the main library had 1,593,620 volumes, in addition to independent collections ranging from 5,000 to 50,000 in 41 general branches, ten senior high school branches and eight junior high school branches. The circulation of books in 1926, in addition to those used on the main shelves of the central library, was 11,611,107. The John Crerar library, endowed in 1889 by John Crerar, wealthy manufacturer of railway supplies, had in 1927 520,000 volumes and 300,000 pamphlets on social, physical, natural and medical sciences and their applications. It occupies a large building across the street from the main building of the public library at Randolph street and Michigan avenue. The Newberry library, endowed by a bequest of Walter L. Newberry, in 1927 contained 449,099 volumes, chiefly in the field of the humanities, history and literature. These three libraries co-operate to avoid useless duplication and each has certain special fields. Other important collections are the library of the University of Chicago, the Ryerson library in the Art Institute, devoted to fine arts and travel, the library of Northwestern University, the Burnham library of architecture, the Field Museum, the Virginia, the Lewis Institute, the Elbert H. Gary law library, the Loyola university, the Garret Biblical institute and the municipal reference library containing a great collection of documents and data on municipal government in Chicago and elsewhere. Many trade, engineering and professional organizations maintain special libraries at their national or sectional headquarters in Chicago.

Universities and Colleges.—The leading university is the University of Chicago (*see* CHICAGO, UNIVERSITY OF). The professional departments of Northwestern University are mostly located in Chicago while the academic and theological departments are in the suburb of Evanston. Northwestern University was organized in 1851 by the Methodist Episcopal Church and still sustains nominal relations with the denomination. In 1927 it had a student enrolment of 11,888 with 690 instructors. Roman Catholic institutions of importance in Chicago include Loyola University, chartered in 1870, with a department of law called Lincoln college, and a medical department; and De Paul University. The College of Physicians and Surgeons is the medical department of the University of Illinois, at Champaign-Urbana. Theological schools independent of the universities include the McCormick Theological seminary (Presbyterian); the Chicago Theological seminary (Congregational, opened 1858, and including German, Danish-Norwegian and Swedish institutes); the Western Episcopal Theological seminary; a German Lutheran Theological

seminary, and an Evangelical Lutheran Theological seminary. There are a number of independent medical schools and schools of dentistry and veterinary surgery. The Lewis Institute (bequest 1877, opened 1896), designed to give a practical education to boys and girls at a nominal cost, and the Armour Institute of Technology, one of the best technical schools of the country, provide technical education and are well endowed. The Armour Institute was founded in 1892 by Philip D. Armour, and was opened in 1893.

Newspapers.—The daily newspapers (morning) published in the English language are the *Chicago Daily Tribune* (which also publishes a European edition in Paris) and the *Herald-Examiner*. The afternoon papers are the *Daily News*, the *Chicago Evening American*, the *Chicago Evening Post* and the *Chicago Journal*. The *Tribune*, *News* and the *Post* are nominally Republican, the *Herald-Examiner* and the *American* nominally Democratic, and the *Journal* is Democratic. In the number of publications, though not in circulation, the foreign language press outstrips the English publications—foreign language dailies including publications in Polish, Yiddish, German, Swedish, Czech, Greek and Italian. The city is the largest American printing centre in point of volume of output, and many trade, labour, scientific and religious publications are included in its total of approximately 800 periodicals. In 1920 the city's first financial daily, the *Chicago Journal of Commerce*, was established. The Joseph Medill School of Journalism named after the founder of the *Chicago Tribune* was opened as a part of Northwestern University in 1921, the *Tribune* underwriting any deficits for a period of years.

Industry and Commerce.—Chicago's situation at the head of the most south-western of the Great Lakes has given it great importance in trade and industry. The growth of its trade has been marvellous. Since the beginning of the 20th century, however, Chicago has undergone an industrial and commercial transformation roughly parallel to that of the United States as a whole. The city's paramount position as a great market in the 19th century was associated with the extractive industry of the American economy of that day, and Chicago's trade consisted principally in the assembly and distribution of the raw crops and resources of fields and forests—her industries were mainly processing raw products, such as meat-packing, wood-working, flour-milling, tanning, etc. While these great industries remain important, Chicago's leading position in regard to them, except in meat-packing, has disappeared, but this has been made up many times by the growth of an intensive industrialism. The city has made great strides as a centre of the iron and steel industry, including many other products such as cement. The Calumet steel and iron region south of the city has made tremendous progress since the founding of the steel city of Gary in 1906 just across the Indiana State boundary, and in manufacturing plants for heavy iron and steel products the Chicago region now stands to the Pittsburgh district—America's leading steel region—in the ratio of 10 to 13, while the operations are more continuous in the Chicago district.

The last years of the 19th century showed, however, an inevitable loss to Chicago in the growth of Duluth, Kansas city and other rivals in strategic situations. In particular the struggle of the north and south railway lines in the Mississippi valley to divert grain and other freight to ports on the Gulf of Mexico caused great losses to Chicago. An enormous increase in the cereal trade of Philadelphia, Baltimore, Newport News and Norfolk was partly due to the traffic eastward over lines south of Chicago. The traffic of the routes through Duluth and Canada does not, indeed, represent actual losses, for the traffic is largely a new growth; but there has been nevertheless a considerable drain to these routes from American territory which was once tributary to Chicago. Altogether the competition of the Gulf roads and the lines running south-west from Duluth had largely excluded Chicago by 1899 (according to its Board of Trade) from the grain trade west of the Missouri river; its facilities for receiving and distributing remain nevertheless unequalled, and it still practically monopolizes the traffic between the northern Atlantic seaboard and the Central West. The city's position as a gateway for passing trade is indicated by the fact that one-eighth of the traffic of its

railway terminals is (1928) through traffic.

With the completion of the lakes to the gulf waterway, and the conversion of Chicago into a virtual seaport by the construction of a shipway through the lakes and the St. Lawrence river to the Atlantic, Chicago may again become relatively as important as it was in the 19th century, as an outlet for the midwest and the mountain States. New York alone among American cities has a greater trade. Chicago is the greatest railway centre, the greatest grain market, the greatest livestock market and meat-packing centre in the world and holds world primacy in a large number of smaller manufacturing industries.

While Chicago has not entered the field of international finance to any great extent its domestic financial power is growing very rapidly and as a distributor of investment securities it is likely to challenge the supremacy of New York at no distant day. The annual clearings of its associated banks amounted to \$35,958,200,000 in 1927. At the close of that year the banks of Chicago had combined loans and discounts of \$1,938,268,000, deposits of \$2,830,239,000, cash resources of \$620,043,000 and savings deposits of \$694,572,000. The wholesale trade was estimated in 1875 at \$293,900,000 and in 1905 at \$1,781,000,000. A census of distribution by the United States department of commerce covering the year 1926 showed wholesale trade of the city of Chicago proper to be \$4,844,761,000. The retail trade of the city in 1926 totalled \$1,981,140,000. Persons employed in wholesale trade numbered 122,181; those employed in retail trade numbered 183,217. Although the Chicago board of trade remains the greatest speculative grain market in the world, governmental regulations of increasing stringency have restricted trading upon the board. However, memberships on the board are more valuable than ever and the body has voted the erection of a gigantic building to cost \$10,000,000 on the site of the old building in which the price of the world's bread has been determined on so many momentous occasions. The grain elevators are yet among the sights of Chicago. They are enormous storehouses into which the grain is elevated from ships and cars, sorted into grades and reloaded for shipment, all the work being done by machinery. America has almost ceased to be an exporter of beef, but shipment of pork products—mostly hams, shoulders, bacon and lard—is yet an important item in Chicago's foreign trade. Chicago's direct foreign trade is mostly by rail through other ports, although vessels of less than 14ft. draft come in from the Atlantic on special trade voyages. Imports for the fiscal year 1927 (mostly in bond by rail) amounted to \$51,350,274. Direct exports for the fiscal year 1927 were valued at \$19,917,212.

The value of manufactures in the Chicago metropolitan district, comprising the counties of Cook, Du Page, Kane, Will and Lake in Illinois and Lake in Indiana—all within the periphery of the Chicago railway terminal system, was in 1925 according to the bureau of the census \$4,688,696,674 or 7.47% of the value of all manufactures in the United States. The population of the metropolitan district is 3.47% of the population of the United States. The number of establishments in 1925 was 10,540, of wage-earners 499,823, amount of wages \$765,847,023, cost of materials \$2,624,004,772, value added by manufacture \$2,064,691,902.

Products of leading industries of Chicago proper were valued as follows: slaughtering, \$571,051,743; electrical machinery, \$156,409,829; railway cars, \$124,882,262; men's clothing, \$122,162,013; women's clothing, \$51,369,733; bread and bakery products, \$85,446,640; foundry products, \$142,594,145; iron and steel works, \$115,698,216; motor vehicles, bodies of motor vehicles, motorcycles and bicycles, \$92,940,238; paints and varnishes, \$66,747,748; printing, book, job and newspaper, \$268,205,989; furniture, \$68,137,437; leather, tanned and curried, \$23,736,563; and soap, \$27,904,053. The International Harvester company, successor to the McCormick Harvester company, is the largest manufacturer of agricultural machinery in the world and the Western Electric company holds the same position in the manufacture of telephone equipment. The Pullman company not only manufactures railway freight and passenger cars but operates sleeping and drawing-room cars on practically all the railways of the country. Meat-packing, for which Chicago is best known, is the greatest local industry. In the enormous stock-yards (about 500ac. in

area) from two-thirds to four-fifths of the cattle and hogs received are killed, and sent out in various forms of prepared meats and by-products (lard, fertilizers, glue, butterine, soap, candles, etc.).

Public Utilities.—The development of manufacturing in Chicago has gone hand in hand with an equally remarkable development of public utility services, without which Chicago's industrialism would be impossible, for much of its factory industry is due to an abundance of cheap electric power, supplied by a highly efficient system of interconnected generating stations. The electrical output of the three associated and interconnected electrical companies in the Chicago industrial area in 1927 was 4,476,000,000 kw.hrs.; the generating capacities totalled 2,756,000 h.p. There were over 900,000 consumers of electric light and power in Chicago. The company serving the incorporated city consumed 3,360,000 tons of coal in 1927 and for condensing purposes alone pumped an average of 1,220,000,000 gallons of water per day; more than the daily pumpage of the city water works by about 400,000,000 gallons. In 1927 the local gas industry served 830,000 consumers within the incorporated city and was interconnected by pipe lines with producing plants and consumers within a wide radius of the city. It is beginning the use of surplus by-product gases generated in the steel and iron industry. Telephonic communication is in almost universal use by householders and in 1927 the work of converting the telephone system to the automatic switching type was far advanced.

Administration.—Chicago is governed under a general city charter law of Illinois of 1872, accepted by the city in 1876, but the charter has been amended in some minor particular at every biennial session of the Illinois State legislature since that date. The essential framework of government, however, remains as it was originally adopted, and the efforts of municipal reformers to institute a complete new system of local government have been defeated, even when submitted to a referendum of the voters. Although the government remains apparently archaic and highly complicated, it really works about as well as that of the average American municipality, and the faults of municipal government and politics in Chicago relate rather to the polyglot character of the population, than to the forms of government. Chicago remains a good example of the "councilmanic" form of municipal government, once almost universal in America, but the legal and *de facto* powers and influence of the mayor have grown, even as the power of the presidential office has grown at the expense of congressional prestige and effectiveness in the Federal Government. A common council consisting of one alderman from each of the 50 wards is elected biennially. It controls the budget, police, excise (diminished in importance since the outlawry of the liquor traffic by national legislation), city contracts and franchises. The latter are subject to popular referendum however. The council confirms appointments by the mayor and may pass legislation in spite of his veto, by a two-thirds vote. The mayor, selected every four years, is the executive head of the city. He appoints a cabinet, consisting of the heads of city departments, but most city employees are under a civil service law and are removable only under processes and tribunals provided by that law. There are several commissions in charge of city functions—such as the school board, the public library commission, the commission in charge of elections, and that in charge of the municipal tuberculosis sanatorium. Administration of several pension funds for city employees is also committed to a number of commissions.

Like other American cities with the exception of Denver, Baltimore and St. Louis, Chicago has a dual city and county government. The county of Cook, which contains Chicago, retains practically all of the extensive government functions of rural counties of the type which arose in Virginia and the southern colonies, and in which the county was the real unit of local government. This complication of dual government in Cook county extends to the suburbs of Chicago, which have separate municipal organizations, while the county itself was laid out after 1848 in townships, somewhat on the New England town model. It was not until 1900 that the town organizations within the territory gradually annexed to the original village of Chicago were deprived of their politi-

GRANT PARK AND A VIEW OF THE "LOOP"

1. Buckingham fountain in Grant park, a memorial to Clarence Buckingham, the largest fountain of its type in the world. It is modelled to a certain extent after the Latona fountains at Versailles, and is especially effective at night when coloured lights play upon it
2. Aerial view of the "loop" from the south-west side, showing Lake Michigan and part of the north side. The passage of the Chicago river can be traced from its mouth southward through the city. In the right background is Navy pier, formerly known as the Municipal pier

cal structure and divested of governmental functions within the city, and as late as 1903 ten townships exercised taxing power within the municipal area. This complicated system of government is growing, despite efforts to simplify it. A plan for the consolidation of local government was rejected by the people in 1920. In addition to the original duplications of government, new quasi-governmental bodies have been set up for special purposes and in some cases granted police and tax powers. There are three great park commissions within the city—the members of the Lincoln and West Side park boards are appointed by the governor of Illinois; the members of the South park board, the most important of all, are elected by the judges of the circuit court of Cook county. The three great park boards have powers of taxation, debt incurrence and police. There are also 15 small park districts, some of them with governing boards elected by the people of the areas served. Chicago citizens in 1927 were under some sort of jurisdiction or in contact with about 25 kinds of government, more or less dissociated from the others. On the other hand in 1906 the archaic system of administering petty justice through the justices of the peace was abolished and a co-ordinated municipal court with numerous judges and a chief justice was established. The juridical system is complicated by the fact that the circuit court is a constitutionally established court of the State of Illinois. The superior, municipal and other special courts are created by statute. The sanitary district, practically an independent government in itself, with powers of tax levy and debt making, is superimposed over the territory of Chicago and Cook county. Both the State of Illinois and the Federal Government have also extended the legislative and administrative regulation of industry and commerce, and maintain large staffs of officials and inquisitors in Chicago. The school board has been nominally separate from and almost independent of the city government in its powers since 1857. The forest preserves adjacent to the city's boundaries are also quasi-governmental bodies exercising some sovereign powers.

The initiative and referendum in local matters have been made possible by the State, and this power has been frequently exercised. Increases of the public debt are subject to popular vote, but financial arrangements under such a complex system of government are naturally loose and inefficient—co-ordinated budgeting being virtually impossible. The grant of independent taxing power to so many governmental bodies, in the Chicago area, as elsewhere in America, is one result of State constitutional limitations upon the public debt. Chicago, as a municipal corporation, is prohibited from incurring debt in excess of 5% of the value of the property within the city. The inevitable result of such a restriction, when a great public necessity has arisen, is the creation of another taxing body not limited by pre-existing debt limits covering a given territory, within the jurisdiction of an existing governmental body.

Finances.—The budget for the city of Chicago proper for 1928 called for the expenditure of \$225,208,442, of which \$90,600,000 was to be expended by the school board, \$19,000,000 by the water department, \$2,805,970 by the municipal tuberculosis sanatorium, \$1,200,000 on Calumet Harbour, \$2,788,000 by the public library board, \$1,090,000 by the board in charge of firemen's pensions, \$3,597,000 by the board administering police pensions, and \$2,180,000 by the board in charge of pensions for other municipal employees. Other funds in the budget out of which a great variety of expenses are met, such as police, fire department and street and bridge maintenance, are the corporation fund of \$59,170,000, the vehicle tax fund of \$4,510,000 and the various bond funds amounting to \$38,477,472. Chicago revenue for 1926, not including the proceeds of bonds issued, was \$226,813,000 or \$74.41 *per capita*; in 1925, \$68.45; in 1917, \$35.20. These figures cover the government of the city proper, the independent school districts, sanitary district, park districts, and other independent districts practically co-extensive with the city, not excepting county departments and expenses for the county area within the incorporated city. The revenue was derived as follows: special and poll taxes, \$149,926,000; licences \$8,784,000; special assessments and charges, \$16,899,000; subventions,

donations and pension assessments, \$6,040,000; earnings of general departments, \$7,490,000; earnings of public service enterprises, \$12,363,000; and all other revenues \$13,750,000. Chicago's net debt *per capita* in 1926 was \$67.07, lower than that of any of the 14 American cities of over 500,000 population, except St. Louis, which had a *per capita* net debt of \$30.29.

Transit Problems.—Chicago's conspicuous failure as a city has been in the lack of providing adequate rapid transit facilities. In 1928 the traction question remained unsettled and was still a "football of politics," although the popular temper as manifested at the referendum election of 1925, when a compromise plan for instituting municipal ownership was defeated by a large majority, indicates that an eventual solution will be found on lines of ownership and control by a strictly regulated private corporation. At the mayor's election in 1905 the successful party stood for immediate municipal acquisition of all roads. Meanwhile, under the State Referendum Act, the city in 1902 voted overwhelmingly for municipal ownership and operation (142,826 to 27,990); the legislature in 1903 by the Meuller law gave the city the requisite powers; the people accepted the law, again declared for municipal ownership, and for temporary compulsion of adequate service, and against granting any franchise to any company, by four additional votes similarly conclusive. At last, after tedious negotiations, a definite agreement was reached in 1906 assuring an early acquisition of all roads by the city. The issue of bonds for municipal railways was, however, declared unconstitutional that year. At the municipal elections of 1907 there was a complete reversal of policy; a large majority voted this time against municipal ownership in favour of leaving the working of the street railways in private hands and strengthening the powers of municipal control. For 20 years after 1907 the surface car lines of Chicago were operated under unified management and rendered excellent service. The system was completely rebuilt, and that work led to the repaving of the city, so that the coming of the automobile age found Chicago comparatively well equipped for motor transport. But with the growth of the city and the congestion of the streets by motor traffic, transportation by surface electric railways became too slow to meet the demands of the population. In the meantime the construction of elevated railway lines practically ceased, except for extensions outside the incorporated city limits where the political factor did not enter into calculations. Proposals for the consolidation of the elevated and surface lines and the construction of subways, either independent systems or to be operated in connection with the elevated or surface lines or both, were made without number and the city spent great sums upon engineering investigations and reports. With the rise in the general price level during the World War the five cent fare became impossible and increases were obtained either through the Illinois commerce commission or by court action. This aroused more popular resentment and revived traction as a political issue.

Under the franchise arrangement of 1907 the city received for 20 years 55% of the divisible net receipts of the surface lines—after payment of 5% on agreed capital—a total of \$39,398,357.90, which with interest earned on the fund over the 20 years was available in 1927 for construction of modern transit facilities. The city also has power to subject adjacent property to special assessments in aid of subway construction. When the 1907 franchise expired in 1927 no agreement was reached. The lines are operated under temporary agreements pending an adjustment of the conflicting claims and proposals and the enactment of legislation by the State of Illinois to empower the city to take the necessary steps toward a re-organization of the entire transit system. The surface lines, consisting of 1,079m. carried 880,326,000 revenue passengers in 1927—a total of 1,580,000,000 rides including transfer passengers. The elevated system operates 217m. of track, in double, triple and four track sections, and carried 226,000,000 passengers in 1927.

Education and Charity.—The school board is appointed by the mayor. Since 1904 a merit system has been applied in the advancement of teachers; civil service rules cover the rest of the employees. Free evening schools, very practical in their courses,

are utilized mainly by foreigners. Vacation schools were begun in 1896. As far as possible the school buildings are kept open for school lectures and entertainments, serving as social centres; thus a more adequate use is made of the large investment which they represent. In all the public schools manual training, household arts and economy, and commercial studies are a regular part of the curriculum. A department of scientific pedagogy and child study (1900) seeks to secure a development of the school system in harmony with the results of scientific study of children (the combination of hand and brain training, the use of audio-visual methods, an elastic curriculum during the adolescent period, etc.). Enrolment in the schools in 1927 totalled 521,786. The teaching staff numbered 12,536. In the year ending on June 30, 1927, new school buildings were erected at a cost of \$16,100,606.64, and \$2,636,088.60 was spent for new school sites. There were 24 high schools, 14 junior high schools and 306 grade schools in 1927.

Hospitals, infirmaries, dispensaries, asylums, shelters and homes for the defective, destitute, orphaned, aged, erring, friendless and incurably diseased; various relief societies, and associations that sift the good from the bad among the mendicant, the economically inefficient and the viciously pauper, represent the charity work of the city. The most important charitable societies of the city are the United Charities of Chicago (1909), the United Hebrew Charities (1857), and the Associated Jewish Charities (1900). A famous institution is Hull House, a social settlement of women, which aims at being a social, charitable and educational district centre. It was established in 1889 by Miss Jane Addams, who became the head-worker, and Miss Ellen Gates Starr. It includes an art building, a free kindergarten, a fine gymnasium, a crèche and a diet kitchen; and supports classes, lectures and concerts. It has had a very great influence throughout the United States. The major portion of social work in Chicago is performed by 38 general welfare agencies, 24 general health agencies, 110 hospitals and 73 dispensaries, 55 infant welfare centres, 34 agencies for family relief and rehabilitation, 148 child-caring institutions, 70 boarding clubs and hotels for men and women, 29 employment and vocational guidance organizations, 60 homes and emergency shelters for adults, 49 summer camps, 60 institutions for civic, legal and protective work. There are also institutions for the shelter of abandoned and stray dogs, cats and other animals. The total financial outlay, public and private for such work has been estimated by the Chicago Council of Social Agencies at \$50,000,000 per year, and it is increasing much faster than the rate of population growth. One of the most important municipal undertakings is the municipal tuberculosis sanatorium, erected after 1909, in which year a site of 164ac. was acquired in the north-western part of the city.

Population.—Of the total population of Chicago as counted in the census of 1920, 805,482 out of a total of 2,701,705 were foreign-born immigrants, 888,496 were children of immigrants, and 252,320 were of mixed parentage, 642,871 native white of native parentage, 109,594 negro, 94 American Indians, 2,353 Chinese and 233 Japanese. The effect of the restrictive immigration laws enacted after the World War is already notable in the population of Chicago. A heavy influx of native-born white population from the farms and smaller cities, the growth of the negro population and an increased influx of Mexicans, not subject to the quota restrictions imposed upon Europe and the Eastern hemisphere, have already had discernible effects, but the business and political life of the city is still largely coloured by the influence of national and racial blocs. There are over 42 nationalistic and racial organizations of one kind or another, which maintain secretariats in the business district, and many others with headquarters in outlying parts of the city. The largest, most completely organized and politically influential nationalistic groups are the Germans and Irish—very much "Americanized" and losing cohesion—Poles, Swedes, Czechs, Italians, Yiddish speaking Jews. There are still some 40 or more languages spoken in Chicago, and many sections of the city are to all intents and purposes foreign quarters, but the process of assimilation has made the city much more homogeneous than it was at the beginning of the 20th century. In 1920 the negro population was 109,594, an increase of 148.5%

over the preceding census. The influx of negroes was due to the demand for unskilled labour, especially in the packing industry, during the period of the World War, when European immigration was slight. A shortage of housing facilities for these negro labourers was one of the underlying causes of the race riots of 1919. The negro influx slackened during the industrial depression of 1920-21, to be resumed in 1923. In the following year it again declined, and with the rapid development of conveyor and construction machinery to displace manual labour the movement has probably passed its crest.

Partly because of the high percentage of youthful adults in the population of Chicago, drawn to the city from other lands and from the rural districts and smaller cities of the United States, the death rate of the city is among the lowest urban rates in America. In 1925 the death rate was 11.5 per 1,000 of population. Births maintain a lead over deaths, so that the city has a substantial, natural rate of increase of population, irrespective of immigration. The growth of Chicago has been remarkable even for American cities. Any resident of four-score years living in 1900 had seen it grow from a frontier military post among the Indians, to a great metropolis, fifth in size among the cities of the world. In 1828 what is now the business centre was fenced in as a pasture; in 1831 the Chicago mail was deposited in a dry-goods box; the tax levy of 1834 was \$48.90, and a well which constituted the city water-works was sunk at a cost of \$95.50; in 1843 pigs were barred from the town streets. Such facts impress upon one, as nothing else can, the marvellously rapid growth of the city.

History.—The river Chicago (an Indian name of uncertain meaning, but possibly from Ojibwa she-kag-ong, "wild onion place") was visited by Joliet and Marquette in 1673, and later by La Salle and others. It became a portage route of some importance, used by the French in their passage to the lower Illinois country. In 1804 the United States established here Ft. Dearborn. In 1812, during the Indian War of Tecumseh, the garrison and settlers, who had abandoned the fort and were retreating toward safety, were attacked and overpowered by the savages at a point now well within the city. The fort was re-established and fitfully occupied until its final abandonment in 1837.

When Cook county was organized in 1831, Chicago, then a tiny village, became the seat of justice. It became a town in 1833 and a city in 1837. By that time Chicago was confident of its future. The Federal Government had begun the improvement of the harbour, and the State had started the Illinois and Michigan canal. There was a Federal land-office also, and the land speculator and town promoter had opened a chapter of history more picturesque, albeit sordid, than in any of the old French days. The giant growth of the lake trade had drawn attention before railway connection was secured with the east in 1852, making progress even more rapid thereafter. During the Civil War a large prison-camp for Confederate prisoners, Camp Douglas, was maintained at Chicago. In 1870 the city had 306,605 inhabitants and was already a commercial centre of immense importance. In 1871 it suffered a terrible calamity. On Oct. 8, a fire broke out near the lumber district on the west side. Two-thirds of the city's buildings were wood, and the summer had been excessively dry, while to make conditions worse a high and veering wind fanned the flames. The conflagration leaped the river to the south and finally to the north side, burned over an area of 3½m., destroyed 17,450 buildings and property valued at \$196,000,000 and rendered almost 100,000 people homeless; 250 lost their lives. The flames actually travelled 2½m. in an air-line within 6½ hours. Thousands of persons, fleeing before the flames and fire-brands, sought refuge on the shore and even in the waters of the lake. Robbery, pillage, extortion, orgies and crime added to the general horror. In the south side the fire was checked on the 9th by the use of gunpowder; in the north (where the water-works were early destroyed) it had extended almost to the prairie when rainfall finally ended its ravages, after about 27 hours of destruction. With the exception of the San Francisco fire of 1906 this was the greatest fire of modern times. A vast system of relief was organized and received generous aid from all parts of the world.

The money contributions from the United States and abroad were \$4,996,782; of this foreign countries contributed nearly \$1,000,000 (England half of this). These funds, which were over and above gifts of food, clothing and supplies, were made to last till the close of 1876. Out of them temporary homes were provided for nearly 40,000 people; barracks and better houses were erected, workmen were supplied with tools, and women with sewing-machines; the sick were cared for and the dead buried; and the poorer classes of Chicago were probably never so comfortable as during the first two or three years after the fire. The rebuilding of the city was accomplished with wonderful rapidity. The business district was largely rebuilt within a year, and within three there were few scars of the calamity. Wood was barred from a large area (and subsequently from the entire city), and a new Chicago of brick and stone, larger, finer and wealthier, had taken the place of the old. Business and population showed no set-back in their progress. The solidity and permanence of this prosperity were confirmed during the financial panic of 1873, when Chicago banks alone, among those of the large cities of the country, continued steadily to pay out current funds.

In its later history Chicago has been a storm centre of labour troubles, some of them of specially spectacular character. There were great strikes in the packing industry in 1886, 1894 and 1904. But more noteworthy are the railway strike of 1894 and the unsuccessful teamsters' strike of 1905. The former began in the works of the Pullman Car Company, and its leader was Eugene Victor Debs. When the contentions of the Pullman employees were taken up by the American Railway union the strike immediately extended to tremendous proportions. Chicago, as the greatest railway centre of the country and the home of the strike, was naturally the seat of the most serious complications. There was much rioting and destruction of property, and the railway service was completely disorganized. President Cleveland, on the ground of preventing obstruction of the mail service, and of protecting other Federal interests, ordered a small number of Federal troops to Chicago. Governor Altgeld denied the inability of the State to deal with the difficulty, and entered a strong protest against Federal interference; but he did nothing to put down the disorder. Federal troops entered the State, and almost immediately the strike collapsed. The high officials of the Railway union, for ignoring a court injunction restraining them from interfering with the movement of the mails, were imprisoned for long terms for contempt of court.

Out of the strike in the McCormick works in 1886 there sprang another famous incident in Chicago's history. The international anarchists of Chicago had been organized in groups about two years earlier, and were very active. They were advocating a "general strike" for an eight hour day, and the tense excitement among the labourers of the city, owing to the McCormick strike, induced unusually extreme utterances. There was a riot at the McCormick works on May 3, in which several men were killed by the police. An anarchist meeting was called for the next day at the Haymarket, a square in Randolph street, and when the authorities judged that the speeches were too revolutionary to be allowed to continue, the police undertook to disperse the meeting. A bomb was thrown, and many policemen were injured, seven fatally. No person could be proved to have thrown the bomb, or to have been directly implicated in its throwing; but on the ground that they were morally conspirators and accomplices in the killing, because they had repeatedly and publicly advocated such acts against the servants of government, seven anarchists were condemned to death. An application to the United States Supreme Court for a writ of error was unanimously refused.

Four were hanged, one committed suicide, two had their death sentence commuted to life imprisonment, the eighth was sentenced to imprisonment for 15 years. Governor J. P. Altgeld in 1893 pardoned the three in prison on the ground that the jury was "packed" and consequently incompetent, that no evidence connected the prisoners with the crime, and that the presiding judge was prejudiced (*see* an article by Judge J. E. Gary, who presided at the trial, in the *Century Magazine*, April, 1893).

Chicago is still what is known as a union town, but interest in trade-unionism among the city's workers apparently reached its climax in about 1912. After the World War the effect of the greater mechanization of industry, the increased productivity of labour, the immigration restrictions and the maintenance of high wage rates without strikes, was evidenced in greater industrial tranquillity. In the building trades, however, labour unionism remained a powerful factor, despite a great deal of faction and many charges of corruption and of collusion between labour leaders and gangsters pursuing unlawful avocations. A later phase of trade-union organization has been the extension of unionism among small merchants and shop-owners, for purposes of price maintenance and limitation of competition. The extension of this form of organization has been linked with bombing, terrorism and extortion, but the greater part of the trade-union movement in Chicago has not been affected by such methods.

The 400th anniversary of the discovery of America was commemorated by a World's Columbian Exposition held at Chicago. The site was in Jackson park and the adjoining Midway, and included 686ac., of which 188 were covered by buildings. On Oct. 21, 1892—corresponding to Oct. 12, 1492, O.S.—the grounds were formally dedicated, and on the following May 1, opened to the public, continuing open for six months. The number of paid admissions was 21,500,000; of total admissions 27,539,521. The buildings, planned by a commission of architects—of whom John W. Root and Daniel H. Burnham of Chicago were responsible for the general scheme—formed a collection of remarkable beauty, to which the grounds, planned by F. L. Olmstead, intersected by lagoons and bordered by the lake, lent an appropriate setting. The entire cost of the fair is variously estimated at from \$33,000,000 to \$43,000,000, according to the inclusiveness of the estimate; the local cost may be put at \$28,151,169. Of this Chicago gave about \$10,500,000, in addition to a preparatory house-cleaning that cost \$3,500,000; and finally a very small dividend was paid to stockholders. The whole undertaking, carried through with remarkable enterprise, was an artistic and educational triumph of the first order.

In the late '90s the city began a great civic awakening. A civil service system was inaugurated in 1895. The salaries of the councilmen were raised with good results. Numerous reform associations were started to rouse public opinion, such as the Citizens' Association of Chicago, organized in 1874, the Civic Federation (1894), the Municipal Voters' League (1896), the Legislative Voters' League (1901), the Municipal Lectures Association (1902), the Referendum League of Illinois (1901), the Civil Service Reform Association of Chicago, the Civil Service Reform Association of Illinois (1902), the Merchants' Club, the City Club (1903), and Law and Order League (1904), Society of Social Hygiene (1906); and many of the women's clubs took an active part. They stood for effective enforcement of the laws, sanitation, pure food, public health, the improvement of the schools and the widening of their social influence, and (here especially the women's clubs) aesthetic, social and moral progress. The Merchants' Club reformed the city's book-keeping, and secured the establishment (1899) of the first State pawnbrokers' society. The Civic Federation demonstrated (1896) that it could clean the central streets for slightly over half what the city was paying (the city has since saved the difference); it originated the movement for vacation schools and other educational advances, and started the Committee of One Hundred (1897), from which sprang various other reform clubs. The Municipal Voters' League investigated and published the records of candidates for the city council, and recommended their election or defeat. Moreover, a municipal museum was organized in 1905, mainly supported by private aid, but in part by the board of education, in order to collect and make educational use of materials illustrating municipal administration and conditions, physical and social.

The reform movement in its various phases came to its full tide under the administration of Carter H. Harrison, Jr., who was elected in his fifth term in 1911, thereby equalling his father's record of elections to the highest office within the gift of the people of the city. In 1912 District Attorney Waymon closed the

city's tolerated vice district, and it has never been allowed to operate openly since.

With the adoption of the prohibition amendment to the Federal Constitution in Jan. 1919, and the flocking to the city of many adventurous characters attracted by the building boom and the prosperity following the war, there was a growth of violent crime in Chicago. The huge profits of the illicit liquor trade led to the organization of powerful criminal gangs to exploit the traffic, and competition between these organizations led to murder and banditry, which attracted world-wide attention. This was an internecine warfare among the criminal elements, little affecting the great majority of inhabitants. William E. Dever, democrat, was elected mayor in 1923, and to the surprise of the liberal element, which had relied upon the fact that the Democratic party had been historically hostile to prohibition, he announced after his election that the police would be required to act in sympathy and co-operation with the governmental agencies trying to enforce the liquor laws. Mayor Dever was defeated for re-election in 1927 by William Hale Thompson, republican. Thompson promised a liberal administration and charged the school board with permitting propaganda in favour of the British empire and the belittlement of American revolutionary heroes in the histories chosen for school use. In the elections of April and November, 1928, the Thompson machine received a severe setback. The Chicago crime commission began in June an active war against the crime element, and in August a new police commissioner was inducted.

Because of its central location, Chicago has been America's most famous convention city and the scene of much national political history. Lincoln (1860), Grant (1868), Garfield (1880), Cleveland (1884 and 1892), Harrison (1888), Roosevelt (1904), Taft (1908) and Harding (1920) were all nominated for president in Chicago in addition to a number of unsuccessful candidates nominated in stirring conventions. The 28th Eucharistic Congress of the Roman Catholic Church, held in Chicago, June 20-24, 1926, attended by the Papal Legate Cardinal Bonzano and seven other European cardinals, in addition to the American cardinals, brought approximately 1,000,000 pilgrims to the city.

(L. H. L.)

CHICAGO, BURLINGTON AND QUINCY RAILROAD COMPANY, incorporated on Feb. 12, 1849, under the laws of Illinois as the Aurora Branch Railroad, changed its title in 1852 to Chicago and Aurora Railroad, and adopted its present corporate name on Feb. 14, 1855. The company, since then, has acquired numerous other roads, until to-day it owns and operates a system aggregating about 9,400 m., and extending from Chicago to Minneapolis, St. Louis, Kansas City, Omaha and Denver, and thence into Wyoming and Montana, where there are connections with the Northern Pacific and the Great Northern. It owns an interest in the Chicago Union Station Company and various other union depot, terminal and bridge properties, and owns 68% of the stock of the Colorado and Southern Railway Company, which, with its subsidiary lines, the Fort Worth and Denver City and Wichita Valley Railway companies, operates from Wendover, Wyo., to Dallas, Texas, with various branches, and in turn owns one-half interest in the Trinity and Brazos Valley Railway, extending from Fort Worth to Houston, Texas. The parent company itself is controlled jointly by the Northern Pacific and Great Northern railways which own in equal parts over 97% of the capital stock.

The present company, excluding its interest in subsidiary companies, has an investment in railway operating property of about 600 million dollars, and has 220 million dollars of bonds and 1 million dollars par value capital stock outstanding. The railroad handles upwards of 42 million tons of commercial freight each year, of which approximately 40% is mine products, 20% agricultural products, 7% live stock and animal products, 6% lumber and forest products and 27% manufactures and miscellaneous freight. It carried during the year 1927, 6,614,000 passengers, including a heavy commutation traffic in Chicago suburban territory. (H. Ho.)

CHICAGO, MILWAUKEE, ST. PAUL AND PACIFIC RAILROAD COMPANY, successor (Jan. 14, 1928) through reorganization to the Chicago, Milwaukee and St. Paul Railway Company (in receivership after March 18, 1925); owns and operates one of the oldest and largest railroads north and west of Chicago, Ill. The predecessor company was organized and incorporated in 1863 as the Milwaukee and St. Paul Railway Co. "Chicago" being prefixed in 1874. The oldest part of the present system is the first railroad built west from Milwaukee, Wis. (1851), then the Milwaukee and Mississippi Railroad. The "Milwaukee" entered Chicago, Ill., over its own rails in 1873. It reached and was the first direct railroad to St. Paul and Minneapolis, Minn. (1867). Omaha, Neb., was reached in 1882 and Kansas City, Mo., in 1887 and by this latter date the north-west line had been extended to the Missouri river near Mobridge, S.D. Further extension westward was begun in 1906 and in 1909 the road was opened for operation to Seattle and Tacoma, Wash., and Puget Sound; 660 m. of this extension across the mountains were subsequently electrified. In 1921 the Chicago, Terre Haute and South-eastern railway tapping the southern Indiana coal fields was acquired under a 999 year lease. In 1922 the stock of the Chicago Milwaukee and Gary railway was acquired and this road (100 m. has since been separately operated by the "Milwaukee." Gross revenue from all sources in 1927 was \$163,000,000.

The C.M.St.P. and P.R.R. in 1928 served 12 States from Indianapolis on the east to Washington on the North Pacific coast with 11,25 roadway miles. The company's investment in railroad property and equipment amounts to over \$700,000,000. Its capital structure consists in round numbers of \$263,000,000 of fixed interest bearing funded debt; \$183,000,000 of contingent interest bearing debt (income bonds), \$120,000,000 of preferred stock and 1,174,000 shares of no par common stock. \$22,000,000 C.T.H. and S.E. railway and \$3,000,000 C.M. and G. railway bonds are guaranteed as to principal and interest. (H. A. SCA.)

CHICAGO, ROCK ISLAND AND PACIFIC RAILWAY, an American railroad extending from Chicago westward and southward. It dates from a special Act of the Illinois State legislature, approved Feb. 27, 1847, and amended Jan. 27, 1851. Construction began in Chicago Oct. 1, 1851, and the first train ran from Chicago to Joliet, Ill., a distance of 40 m., on Oct. 10, 1852. The road reached the Mississippi river on Feb. 22, 1854, and there was constructed the first bridge over that river between Rock Island, Ill. and Davenport, Ia., which was opened on Sept. 1, 1854. Since that date the growth of the Rock Island was rapid until (in 1928) it comprised over 8,084 m. through 14 Middle Western States, traversing a greater number of commonwealths than any other railroad in the United States, and extending from Chicago to Denver and Colorado Springs, Colo., and Santa Rosa, N.M. and from St. Paul, Minn., to Fort Worth and Dallas, Texas, with lines into St. Louis, Memphis, Kansas City, Omaha, Des Moines, Oklahoma City, Topeka, Alexandria, La., and the principal Mississippi valley centres. The total capitalization of the Rock Island lines in June, 1928, was approximately \$467,000,000, including \$129,000,000 of capital stock. The charter of the Rock Island railway includes the Chicago Rock Island and Pacific and the Chicago Rock Island and Gulf railways. It was in 1928 engaged in the further extension of its lines in the Texas plains territory. The railroad is particularly noted for its very large agricultural and oil traffic. (J. E. G.)

CHICAGO, UNIVERSITY OF, an American university, in Chicago, founded in 1892, privately endowed, co-educational,

non-sectarian, although three-fifths of its 30 trustees must be Baptists. Its presidents have been William Rainey Harper (Sept. 16, 1890–Jan. 10, 1906), Harry Pratt Judson (Feb. 20, 1907–Jan. 9, 1923), Ernest DeWitt Burton (July 12, 1923–May 26, 1925), and since Aug. 21, 1925, Max Mason (resigned 1928). The aims of the university have been research and graduate education. These ideals were set by its first president and expressed in its earliest organization. It has continuously had on its staff men eminent in American letters and science. On its first faculty were nine former presidents of other institutions of higher learning. Nearly 10% of the degrees granted have been doctorates of philosophy. The university is composed of an undergraduate college, of graduate schools of art, literature and science, and a group of professional schools including law, medicine, commerce and administration, education, divinity, library and social service administration. These professional schools have not accumulated as separate units attached to the college as a centre, but are integrated into one educational organization and teach the techniques which rise out of their respective basic sciences. The undergraduate college is closely related to the graduate purposes of the university and numbers little more than one-half of the total student body; the other half are candidates for higher degrees. The astronomical department, the Yerkes observatory, is located on Williams bay, Lake Geneva, Wis., about 65m. from Chicago. The University college and a home study department give courses for the convenience of those who cannot enrol on the quadrangles.

Guided in its early development by the genius of William Rainey Harper and supported by the generosity of John D. Rockefeller, its founder, and the citizens of Chicago, the university has shown a remarkable growth and has continued through its history to expand and intensify its efforts. The list of donors of buildings and endowment includes a large group of the public-spirited citizens of Chicago. During the 35-year history of the university, buildings have been given for student dormitories, commons, assembly and gymnasium, for the university press, for the departments of chemistry, physics, biology, natural history, geology and geography, law, library, oriental studies, theology, classics, commerce and administration, education, modern language, physiology and medicine. From the founder and others have come endowments for the work of these departments.

The grounds of the university include about 160ac., and the university's holdings front on both sides of the Midway Plaisance (which joins Washington and Jackson parks) for almost three-quarters of a mile. On these grounds the main part of the university stands. The buildings are of grey limestone, of Gothic style, and are grouped in quadrangles. In the year ending July 1927 the enrolment was 14,500. This enrolment, which includes that of University college and of the home study department, is distributed over the four quarters of the normal academic year, between 5,000 and 6,000 students being in residence at the quadrangles at any one time. The University of Chicago was the first American university to adopt the summer quarter as a regular part of the academic programme, thereby increasing opportunities for teachers in other schools to do scholarly work in their summer vacations and increasing by one-third the usefulness of the academic plant. The University of Chicago Press, the first university press to be organized in the United States, publishes the results of research at this and other universities. The existence of this press encourages research by making possible the publication of its results and by presenting to the general public in attractive form the products of scholarly effort. The press publishes from 50 to 60 books annually besides 13 journals, most of which are edited at the university. These journals are: *American Journal of Semitic Languages and Literature*, *American Journal of Sociology*, *Journal of Political Economy*, *Modern Philology*, *Classical Philology*, *Journal of Geology*, *Astro-Physical Journal*, *Botanical Gazette*, *Journal of Religion*, *Physiological Zoology*, *International Journal of Ethics*, *Social Service Review* and the *Journal of Business of the University of Chicago*.

The years 1916–27 were a period of significant growth in medical science at the university. Rush Medical college was affiliated with the university in 1898, integrated into the university in 1924

and until 1927 did the clinical teaching of the university's medical school. In 1916 a programme was formulated by President Judson to build a hospital on the quadrangles in close proximity to the basic and clinical sciences. Funds were raised for this purpose. The construction of the new university clinics building, which houses the clinical departments and hospital, was begun in 1925 and completed in 1927. Medical teaching and research are in progress on the quadrangles, although Rush Medical college continues to teach a part of the medical students during their clinical years. Assured additions to the buildings and endowment of the medical group will greatly expand its scope. The whole enterprise is a closely correlated attack on problems of disease through basic and clinical sciences and a project for training medical students in scientific methods of thought and practice. The major body of medical teachers and investigators are full-time members of the university staff.

The financial history of the university is in large part that of the liberality of the founder, John D. Rockefeller. He made the initial contribution of \$600,000 on which the university was founded. His aggregate gifts over a period of 20 years total more than \$34,700,000; the final gift of \$10,000,000 was made in 1910 (\$1,500,000 to be used for a university chapel, the balance for endowment, erection of buildings and purchase of real estate). Gifts to the university other than those of Rockefeller aggregate \$47,800,000 since its founding. A development effort, initiated in 1923–24 under President Burton, secured over \$9,250,000 for general endowment and buildings. The annual budget for the year 1927–28 totalled over \$5,700,000. On Jan. 1, 1928, the total of gifts received by the university, including unpaid instalments on gifts, was \$82,500,000.

The years 1924–27 saw a remarkable expansion of physical plant, increase of endowment and intensification of effort through all departments. On July 1, 1927, the university libraries contained 775,660 volumes, exclusive of pamphlets. On the same date 23,959 degrees had been granted by the university, of which number 2,055 were doctorates of philosophy. The number of doctor of philosophy degrees granted in 1926–27 was 164. The faculty numbers 636, of whom 166 are full professors, 64 associate professors and 108 assistant professors. The work of the university has been greatly assisted by the general education board and the Laura Spelman Rockefeller memorial. Among their principal subventions were those promoting research in medicine, social sciences, physical sciences and the humanities. (J. Do.)

CHICAGO ACADEMY OF SCIENCES, THE, an institution organized at Chicago, Ill., on Jan. 13, 1857, "to promote and diffuse scientific knowledge," and one of the oldest scholarly bodies existing in Illinois. The collections of the academy, considered at the time among the most valuable in America, were in the Chicago fire of 1871. With the erection of the new building in Lincoln park in 1893 by Mathew Lafin, a new impetus was given to the establishment of a fine scientific museum. All efforts are being concentrated on exhibits, which are open daily to the public, featuring the wild life, flora and physical characteristics of the Chicago region. When more space becomes available, it is planned to expand the scope of the museum to include all of North America. The academy possesses the Atwood Celestial Sphere and the Chanute aeroplane models. The academy also maintains a library for children, and conducts researches and issues publications directed especially toward a natural history survey of Chicago and vicinity. Lecture courses are carried on throughout the year, and the academy serves as a meeting place for various societies of Chicago, interested in science and conservation. The academy is financed through memberships and endowment funds, plus a regular contribution from the Lincoln park commissioners.

CHICAGO AND NORTH WESTERN RAILWAY COMPANY, a railroad which comprises 8,465.15 m. of railway located in Illinois, Iowa, Nebraska, Wyoming, Wisconsin, Michigan (Northern Peninsula), Minnesota, South and North Dakota. It owned (1928) 1,952 locomotives, 2,214 passenger cars and 72,271 freight train cars. The balance sheet shows fixed property of \$530,000,000, permanent assets of \$30,000,000 more,

total assets \$649,000,000. Its capitalization consists of \$180,840,045.25 of capital stock of which \$22,395,120 is preferred. Its funded debt held by the public is \$277,977,200. The appraisal of the railroad property by the Interstate Commerce Commission adjusted to Dec. 31, 1927, equals \$626,379,174. It is one of the leading railroads of the North-west, serving the agricultural territory tributary to the north and west of Chicago as well as large manufacturing districts and markets. Gross revenue for 1927 was \$150,132,959.69 and net railway operating income of the same year was \$20,257,693.52. It was the first railroad to operate into the present city of Chicago, commencing in Oct. 1848 and expanding from that date to its present proportions.

(F. W. SA.)

CHICAGO HEIGHTS, a city of Cook county, Illinois, U.S.A., on Federal highway 30, 28m. S. of Chicago. It is served by the Chicago and Eastern Illinois, the Chicago, Milwaukee and St. Paul, the Elgin, Joliet and Eastern, the Michigan Central, the Baltimore and Ohio Chicago Terminal, and the Chicago Heights Terminal Transfer railways. In 1900 the population was 5,100; in 1920, 19,653 (31.3% foreign-born white); and in 1930 it was 22,321 by the Federal census. Chicago Heights is an important industrial centre, manufacturing locomotives, cars, steel rails, steel houses, steel castings, terra cotta, bottles, tile, brick, textiles, and various other commodities. The aggregate factory product in 1925 was valued at \$40,659,846. The city was incorporated in 1892.

CHICAGO SANITARY AND SHIP CANAL, in the United States, is an engineering development of special importance to the city of Chicago and surrounding districts. It was first opened in 1900 and the cost of construction with improvements has been about \$70,000,000. Before the construction of the canal Chicago discharged sewerage into Lake Michigan, which was also the source of the water-supply. Such serious contamination resulted that ultimately the extension of water intake pipes for a distance of 8 m. out into Lake Michigan failed to avoid dangerous pollution.

A few miles west of the city, a low limestone ridge marks the division of the watersheds leading to the Des Plaines and Chicago rivers. The Des Plaines, to the west of the ridge, flows southwest to the Illinois river and thence to the Mississippi river. The Chicago river, to the east of the ridge, normally drains into Lake Michigan. A canal channel was dug through the ridge by which the Chicago was connected with the Des Plaines river and at the same time the flow in the Chicago river was reversed from east to west. The refuse of the city is collected in great central city mains and turned into the canal and carried down to the Gulf of Mexico. The canal is 34 m. long, 260 ft. wide and 22 ft. in depth. In 1920 more than 9,000 cu.ft. per second was being drawn from Lake Michigan to carry away the sewerage of Chicago and because of the tremendous growth of the city still greater requirements were anticipated. Another phase of the project, in 1928 undeveloped, was the creation of an all-water route between the Great Lakes and the Gulf of Mexico.

CHICANE, the pettifogging subterfuge and delay of sharp law-practitioners, also any attempt to gain unfair advantage by petty tricks. A more common English form of the word is "chicanery." Chicane was also used until recent years as a term in the game of bridge for the points a player might score if his hand contained no trumps. Chicane is no longer scored, but the term is still used. The word is French, derived either from *chaugān*, Persian for the stick used in the game of polo, still played on foot and called *chicane* in Languedoc (*cf.* the military use of *chicaner*, to take advantage of slight variations in ground), or from *chic*, meaning little or petty, from the Spanish *chico*, small.

CHICHELEY, HENRY (1364-1443), English archbishop, founder of All Souls college, Oxford, was born, the son of a yeoman, at Higham Ferrers, Northamptonshire. He seems to have passed from Winchester college to New college, Oxford, where he took his B.A. in 1392. He was then ordained sub-deacon, but he already held the living of Llanvarchell, in the diocese of St. Asaph. About 1394 he went up to London to practise as an advocate in the principal ecclesiastical court, the court of arches, and from that time an extraordinary number of posts fell to him. In 1396 he

was presented to the rectory of St. Stephen's, Walbrook, and, being ordained deacon and priest later on in the year, he was made archdeacon of Dorset in 1397, and in 1399, canon of the collegiate church of Abergwili, North Wales. In Feb. 1402, he was allowed to use a bull of the pope "providing" him to the chancellorship of Salisbury cathedral and canonries in the nuns' churches of Shaftesbury and Wilton, and in Jan. 1402-3 he became archdeacon of Salisbury. In May 1404, Boniface IX. provided him to a prebend at Lincoln, notwithstanding that he already held prebends at Salisbury, Lichfield, St. Martin's-le-Grand and Abergwili, and the living of Brington.

In July 1405, Chicheley began his diplomatic career by a mission to the new Roman pope, Innocent VII., who was professing his desire to end the papal schism by resignation, if his French rival at Avignon would do likewise. In 1406 he was appointed to treat for peace with the French king, and in the following year he was sent to the new pope, Gregory XII., to end the schism. The pope provided him to the bishopric of St. David's and gave him a bull granting him the right to hold all his benefices with the bishopric.

In Jan. 1409, Chicheley was chosen by the convocation of Canterbury to attend the Council of Pisa, which withdrew obedience from both existing popes and in June elected a new pope. Chicheley now became the subject of a leading case, the court of king's bench deciding, after three successive terms, that he could not hold his previous benefices with the bishopric, and that a papal bull could not supersede the law of the land (*Year-book* ii. H. iv. 37, 59, 79). Accordingly he had to resign livings and canonries wholesale (April 28, 1410), and was enthroned at St. David's in May, 1411. He was with the English force under the earl of Arundel which accompanied the duke of Burgundy to Paris in Oct. 1411, and there defeated the Armagnacs; and in July 1413 was sent by Henry V., with the earl of Warwick, to France to conclude peace. On the death of Archbishop Arundel he was nominated to the archbishopric.

These dates are important as they save Chicheley from the charge, versified by Shakespeare (*Henry V.* act i. sc. 2) from Hall's *Chronicle*, of having tempted Henry V. into the conquest of France for the sake of diverting parliament from the disendowment of the Church. As a matter of fact, the parliament at Leicester, in which the speeches were supposed to have been made, began on April 30, 1414 before Chicheley was archbishop, and the rolls of parliament show that he was not present in parliament. Moreover, parliament was so far from pressing disendowment that on the petition of the Commons it passed a savage act against the heresies "commonly called Lollardry" which "aimed at the destruction of the king and all temporal estates," making Lollards felons and ordering every justice of the peace to hunt them down.

Chicheley was present at the siege of Rouen, and the king committed to him the negotiations for the surrender of the city in Jan. 1419 and for the marriage of Katherine. He crowned Katherine at Westminster (Feb. 20, 1421), and in Dec. baptized her child, Henry VI.

Chicheley is renowned chiefly for his educational foundations. He endowed a chest or loan fund for poor scholars at New college, and another for the university at large. He founded at least three colleges, one at Higham Ferrers and two at Oxford. The licence for the first was given by Henry V. in May 1422. It was closely modelled on Winchester college, and to it was attached an almshouse for 12 poor men. His first Oxford college, St. Bernard's, was founded under licence in mortmain in 1437 for Cistercians. It was suppressed with the Cistercian abbeys in 1539 and granted in 1546 to Christ Church, Oxford, who sold it to Sir Thomas Pope in 1553 for the present St. John's college. The patent for All Souls college, dated May 20, 1438, is for a warden and 20 scholars, to be called "the Warden and College of the souls of all the faithful departed," to study and pray for the souls of Henry V. and Henry VI. and all Englishmen who had died in the wars with France. A papal bull for the college was obtained on June 21, 1439; and further patents for endowments from May 11, 1441, to Jan. 28, 1443, when a general confirmation charter was obtained, for which £1,000 (£30,000 at least of our money) was paid. Only about a quarter of the whole endowment was derived

from alien priories bought by Chicheley from the crown. The rest, particularly the manor of Edgware, which made the fortune of the college, was bought from private owners. Early in 1443 the college was opened by Chicheley with four bishops in state. The statutes, not drawn up until April 2, 1443, raised the number of the college to 40, 16 of whom were to be "jurists" and 24 students of arts and philosophy or theology.

Chicheley died on April 12, 1443, and was buried in Canterbury cathedral.

CHICHEN-ITZÁ or **CHICHEN**, the ruins of an ancient Mayan city of that name, in the south-central part of the State of Yucatán, Mexico, near the boundary of Quintana Roo, about 20° 30' N. lat. and 88° 30' W. longitude. The dry, waterless region round about Chichen-Itzá is of limestone formation, with only an underground water supply, available in but a few places called *cenotes* by the Mayans, where the limestone cap has fallen into the caves through which the water flows. Two large *cenotes* determined the location of the city and gave it its distinctive name, *Chi*, which in Mayan means mouths, *chen*, wells, and *Itzá* the name of the particular Mayan tribe or group which first settled there, the whole meaning the "Mouths of the Wells of the Itzá."

Founded not later than A.D. 530, the settlement for about the first century constituted but a frontier post of a Mayan civilization, "The Old Empire," which at that time was flourishing in the much greater centres to the southward—Copan, Tikal, Quirigua, Palenque and a dozen other equally important cities. When about a century later these great flourishing southern cities were finally abandoned, Chichen-Itzá was also temporarily abandoned, A.D. 668, and the Itzá trekked westward across Yucatán to a new capital, Chakanputun, south of the modern Campeche. Chakanputun was burned in A.D. 944 and the "Holy Men of the Itzá" led their people back to the "Mouths of the Wells of the Itzá" where, in A.D. 964 they re-established their *lares* and *penates* and rebuilt their shrines and altars.

It was the period of the founding of "The New Empire" with Uxmal, Mayapan, and a group of satellite cities, sharing with Chichen-Itzá a superb renaissance of Mayan culture and power. In A.D. 1004 the three greater cities formed an alliance, the League of Mayapan, and the calm and order and prosperity that followed gave rise to a golden age of Mayan religion, science and art, with majestic temples and superb sculptures scattered about the land. At Chichen most of the middle section of the city lying south and west of the Thousand Columns, was built at this time, graced by the Akab'tzib (House of the Dark Writing), the Chichanchob (Red House), the House of the Deer, and parts of the Monjas (Monastery).

In 1201 the League of Mayapan was disrupted by an attack of the Mayapan people upon the Chichen-Itzá because of conspiracies against the League by Chac Xib Chac (The Very Red Man), the Itzan ruler. With the aid of Toltec and Aztec allies from Central Mexico the Mayapan people conquered the Itzans. Henceforth the city was held in thrall by the Toltec-Aztec allies of the Mayapan group. These Toltec-Aztec conquerors brought with them the worship of the fair, golden-haired god, Quetzalcoatl, the "Feathered Serpent," who became "Kukulcan," the Itzan equivalent. During this period Chichen-Itzá rose to heights of prosperity, prominence and architectural development surpassing anything in its earlier history, and highly adorned temples, sanctuaries and shrines rose as if by magic; the principal temple, the so-called Castillo, covering an acre of ground and rising 100 ft. above the plain; the Thousand Columns enclosing a central plaza of more than 5 ac. with pyramid temples, colonnaded halls, sunken courts, terraces and theatres; the Tlachtli-ground or Ball Court; the Temple of the Jaguars; the Temple of the Tables; the Astronomical Observatory; the High Priest's grave; and a host of others.

The two *cenotes*, or wells, upon which the city depended for its very life, constituted the religious, as well as the economic, centre of the city and its culture. Young Itzan maidens were sacrificed to the gods of the wells, as were all kinds of valuables, in gruesome spectacles that drew thousands to share in the ceremonies and the rites, and gave to the city its "holy" character. The

natural setting of the wells, the grandeur of the temples built beside them, the austerity and dignity of the rites, all contributed to the lure, and made Chichen-Itzá the Mecca of the Mayan world for almost two and one-half centuries until in 1884 when it was rather suddenly and finally abandoned, only a few stragglers making their homes there and doing homage to the old gods.

See S. Griswold Morley, "Chichen-Itzá, An Ancient American Mecca," *National Geographic Magazine*, vol. xlvii, No. 1, pp. 63-95 (Jan. 1925). (W. E. E.)

CHICHERIN, GEORGHY VASILIEVITCH (1872-), Russian statesman, the son of an official in the ministry for foreign affairs, was born in Karaul, province of Tambov. He was educated at a Russian Higher school, and at St. Petersburg (Leningrad) university, and entered the diplomatic service in the archives department of the foreign office. From 1897 onward he was gradually drawn into the revolutionary movement. He resigned from the diplomatic service in 1904, renouncing his estates, and went to Berlin, where he followed closely the German Social-Democratic movement. He was at first attached to the Russian socialist-revolutionary party, but later joined the social-democratic party. He was prevented by illness from taking part in the revolution in 1905. He spent 12 years in revolutionary activities in London, Paris and Berlin, being elected secretary of the foreign central bureau of the Russian Social-Democratic party in 1907. In the same year he was arrested in Berlin for the possession of a false passport, and banished from Prussia. During the World War he assisted the anti-war Labour elements in Great Britain, and organized the relief of Russian political refugees, a philanthropic work which had a revolutionary aspect in maintaining contact with Russian revolutionaries. After the Bolshevik revolution in November, when Russia was no longer considered an ally, but an enemy, Chicherin was imprisoned in Brixton gaol on the ground of "enemy associations." On Jan. 3, 1918 he was exchanged for Sir George Buchanan by the Soviet Government, and banished from England. He returned to Russia, and was appointed People's Commissary for foreign affairs in March 1918. In 1922 he headed the Soviet delegation to the conference at Genoa (April 10-May 19) (*q.v.*), of which the unexpected result was a separate treaty between Soviet Russia and Germany. Chicherin conducted Russian policy continuously, from 1918 onwards, having a longer tenure of office than any contemporary European foreign minister. (For the policy for which he was responsible during this period, see *RUSSIA*.)

CHICHESTER, a city and municipal borough in the Chichester parliamentary division of Sussex, England, 60m. S.W. of London by the S.R. Pop. (1931) 13,911. It lies in the coastal plain at the foot of a spur of the South Downs, a mile from the head of Chichester harbour, an inlet of the English channel. The Romano-British town on this site was perhaps Regnum or Regni. Situated on one Roman road in direct connection with London and another leading from east to west, Chichester (*Cissaceaster*, *Cicestre*) remained of considerable importance under the South Saxon kings. In 967 King Edgar established a mint here. Though Domesday Book speaks of 142 burgages in Chichester and a charter of Henry I. mentions the borough, the earliest extant charter is that granted by Stephen, confirming to the burgesses their customs and rights of the borough and gild merchant. This was confirmed by Henry II. By a charter of Edward II., the customs of wool, hides and skins were reserved to the king. Edward III. directed that the Sussex county court should be held at Chichester. Confirmations of the previous charters were granted by Edward III., Richard II., Henry VI., Edward IV., Henry VII., Henry VIII., Edward VI., Philip and Mary, and Elizabeth. A court leet, court of record and bailiffs' court of liberties still exist. In 1604 the city was incorporated under a mayor and aldermen. Since 1295, when it first returned a member, Chichester has been regularly represented in Parliament. Throughout the middle ages Chichester was a place of great commercial importance, Edward III. establishing a wool staple here in 1348. Fairs were granted by Henry I. and Henry VII. Fuller mentions the Wednesday market as being famous for corn, while Camden speaks of that on Saturday as the greatest for fish in the county.

The cathedral church of the Holy Trinity was founded towards the close of the 11th century, after the see had been removed to Chichester from Selsey in 1075. It was consecrated in 1108; Bishop Ralph Luffa (1091–1123) was the first great builder, followed by Seffrid II. (1180–1204), but disastrous fires led to further building throughout the 13th century. Norman work appears in the nave (arcade and triforium), choir (arcade) and elsewhere; but there is much very beautiful Early English work, as in the choir above the arcade. The nave is remarkable in having double aisles on each side, the outer pair being of the 13th century. The church is also unique among English cathedrals for its detached campanile, a massive and beautiful Perpendicular structure with the top storey octagonal. Modern restorations, which include the fine central tower and spire (originally 14th century), the Decorated Lady Chapel and the Perpendicular cloisters, have been effected with great care. The library is a fine late Norman vaulted room; and the bishop's palace retains an Early English chapel. The cathedral is 393ft. long within, 131ft. across the transepts, and 90ft. across the nave with its double aisles. The height of the spire is 277 feet.

At the junction of the four main streets of the town, which preserves its Roman plan, stands the market cross, an octagonal structure in ornate Perpendicular style, built by Bishop Story, c. 1500, perhaps the finest of its kind in the United Kingdom. The hospital of St. Mary was founded in the 12th century, but the existing buildings are transitional from Early English to Decorated. Its use as an almshouse is maintained. Other ancient buildings are the churches of St. Olave, in the construction of which Roman materials were used; the Guildhall, formerly a Grey Friars' chapel, of the 13th century; the Canon Gate leading into the cathedral close; and the Vicars college. The city retains a great part of its ancient walls, which have a circuit of about a mile and a half, and at least in part, follow the line of Roman fortifications. The grammar school was founded in 1497 by Bishop Story. There is a large cattle market, and the town has considerable agricultural trade, but no outstanding industry. A canal connects with Chichester harbour. The diocese includes the whole county of Sussex except a few parishes, with very small portions of Kent and Surrey.

See *Victoria County History*, "Sussex"; Alexander Hay, *History of Chichester* (Chichester, 1804).

CHICHESTER OF BELFAST, ARTHUR CHICHESTER, BARON (1563–1625), lord-deputy of Ireland, second son of Sir John Chichester of Raleigh, Devonshire, was educated at Exeter college, Oxford. He commanded a ship against the Spanish Armada in 1588, and is said to have served under Drake in his expedition of 1595. Having seen further service abroad, he was sent to Ireland at the end of 1598 and was appointed by the earl of Essex to the governorship of Carrickfergus. When Essex returned to England Chichester served under Mountjoy in the war against the rebellious earl of Tyrone, and in 1601 Mountjoy recommended him to Cecil as the fittest person to be entrusted with the government of Ulster. On Oct. 15, 1604, Chichester was appointed lord-deputy of Ireland. He announced his policy in a proclamation wherein he abolished the semi-feudal rights of the native Irish chieftains, substituting for them fixed dues, while their tenants were to become dependent "wholly and immediately upon his majesty." Tyrone and other Irish clan chieftains resented this summary interference with their ancient social organization, and their resistance was strengthened by the ill-advised measures against the Roman Catholics which Chichester was compelled to take by the orders of the English ministers. He himself was moderate and enlightened in his views on this matter, and it was through his influence that the harshness of the anti-Catholic policy was relaxed in 1607. Meantime his difficulties with the Irish tribal leaders remained unsolved. But in 1607, by "the flight of the Earls," he was relieved of the presence of the two formidable Ulster chieftains, the earls of Tyrone and Tyrconnell. Chichester's policy for dealing with the situation thus created was to divide the lands of the fugitive earls among Irishmen of standing and character; but the plantation of Ulster as actually carried out was much less favourable and just to the native population than the

lord-deputy desired. In 1613 Chichester was raised to the peerage as Baron Chichester of Belfast, and in the following year he went to England to give an account of the state of Ireland. On his return to Ireland he again attempted to moderate the persecuting policy against the Irish Catholics which he was instructed to enforce; and although he was to some extent successful, it was probably owing to his opposition to this policy that he was recalled in Nov. 1614. The king, however, told him, "You may rest assured that you do leave that place with our very good grace and acceptance of your services"; and he was given the post of lord-treasurer of Ireland. After living in retirement for some years, Chichester was employed abroad in 1622; in the following year he became a member of the Privy Council. He died on Feb. 19, 1625, and was buried at Carrickfergus.

See Fynes Moryson, *History of Ireland, 1599–1603* (Dublin, 1735); S. R. Gardiner in *Dic. Nat. Biog. and History of England, 1603–1642* (1883).

CHICHIBU, PRINCE: see HIROHITO.

CHICKADEE, common American name (derived from the call-note) for the black-capped titmouse (*Parus*, or *Penthestes*, *atricapillus*), of the north-eastern States. The brown-capped chickadee (*P. hudsonicus*) is resident in Canada. The Carolina chickadee breeds in the south-eastern states. The mountain chickadee (*P. gambeli*) is resident in the Rocky Mountains and westward, and there are several other western forms, one of which, the Alaska chickadee (*P. cinctus alascensis*) is also found in eastern Siberia. All are closely allied with the Old World titmice. See **TITMOUSE**.

CHICKAMAUGA. The battle of Chickamauga was fought (Sept. 19–20, 1863) in northern Georgia between the Federal army of the Cumberland under Rosecrans and Bragg's Confederate army. It was the one great Confederate victory in the West, rendered indecisive by subsequent events. Bragg, afraid of being surrounded in Chattanooga, evacuated the town, which Rosecrans occupied (Sept. 9), and withdrew to Lafayette, where he awaited reinforcements from Virginia under Longstreet before fighting a pitched battle. Rosecrans, when Bragg was found not to be retreating on Rome, hastily concentrated his three corps (Sept. 17), his left (Crittenden) on West Chickamauga creek at Lee and Gordon's mills, 12 m. S. of Chattanooga, and his right (McCook) at Stevens' gap in Lookout mountain. Hood with three brigades joined Bragg (Sept. 18), who that day had begun to move down the east bank of the creek to outflank Crittenden at the mills. His right column crossed 4 m. below, and the movement was to be taken up by the other columns in succession from right to left. Bragg expected to envelop Crittenden and drive Rosecrans back upon Lookout mountain, cutting him off from Chattanooga. Only two Confederate columns crossed that day; three more divisions followed early next morning. But during the night Rosecrans, who had been shifting his army all day to the left, moved Thomas's corps from the centre to the extreme left, to secure his line of retreat to Chattanooga. Thomas's night march defeated Bragg's plan. He was now forced to deliver battle north of the mills, to prevent his own right from being turned. Thick woods concealed the movements of both armies, and the fighting consisted of a series of independent engagements, in which each side alternately outflanked and was outflanked by the other. The battle began (Sept. 19) with Thomas sending a division on a reconnaissance towards the creek. It encountered dismounted cavalry. Both sides hurried up reinforcements and the fighting spread southward, until the whole of Rosecrans' and the greater part of Bragg's forces had been drawn in. The general result was favourable to Rosecrans. He had strengthened his hold on the roads in his rear, but he had put in all his forces, except three brigades of Granger's reserve corps, which were holding Rossville gap, whereas Bragg had still three divisions in hand and during the night was joined by three fresh brigades.

For the morrow's battle Bragg reorganized his army in two wings, the right under Polk, the left under Longstreet, who arrived at 11 P.M., and decided to persevere with his progressive order of attack. Polk was ordered to advance at sunrise (Sept. 20), but the battle only began some hours later. Thomas had strengthened

his line during the night with breastworks. Polk's right overlapped Thomas's left, and two brigades worked round the breastworks into his rear, but were driven out by his reserves. Polk's frontal attacks were repulsed, but Thomas urgently called for reinforcements to secure his left. Rosecrans, believing that Bragg was massing all his troops against Thomas, ordered the best part of three divisions to the left. The withdrawal of a fourth (Wood's), due to a misunderstanding, opened a gap in the Federal line, into which Longstreet stepped. He had organized a heavy column of attack with eight brigades in three lines and another division forming a flankguard on his left. The Federal right wing, now numbering less than 7,000 men, was swept off the field, but not being pursued, rallied in McFarland's gap. Rosecrans, McCook and Crittenden were all caught in the rout and went to Chattanooga. The break in the Federal line occurred about noon. Thomas was left with five divisions (including one from each of the other two corps) and two or three brigades to withstand Bragg's whole army. Longstreet, swinging to the right, endeavoured to reach Thomas's rear. Four of Thomas's divisions continued to hold the breastworks in Polk's front, but Brannan's division and part of Wood's formed a fresh line nearly at right angles with Thomas's main position along Horseshoe ridge, a spur projecting from Missionary ridge. Longstreet had almost enveloped Brannan's right, when two of Granger's brigades under Steedman came to the rescue, and after a desperate struggle dislodged the attacking force, and the Federals held the ridge against renewed assaults, until Longstreet, having vainly called for reinforcements from Polk's wing, put in his reserve division. The Federals were then driven back from the ridge, with the loss of three regiments captured, to the Snodgrass hill, an elevation 50 ft. lower and over 200 yd. to the rear. Thomas, on receiving an order about 4.30 P.M., had already ordered his left wing to withdraw. Polk, who had remained inactive since his repulse in the morning, about 4 P.M. had recommenced his attacks, but the four Federal divisions succeeded in extricating themselves. The right, on Snodgrass hill, was then withdrawn, before Longstreet could renew the attack. The Confederate pursuit was halted at 6 P.M., at which hour the whole field was in their possession. Thomas took up a position for the night covering Rossville, and Bragg's army being too exhausted to attack next day, after dark (Sept. 21) the Federals withdrew unmolested to Chattanooga. The two armies were probably of about equal strength, from 60,000 to 65,000 each. The percentage of losses was heavier than in any other battle of the Civil War, the casualties on either side exceeding 16,000.

See Gracie, *Truth about Chickamauga* (1911); Geer, *Campaigns of the Civil War* (1926). For a very different version, claiming a Federal victory, see Massachusetts Military Historical Society, vol. vii.

CHICKASAW, an American Indian people of Muskogi stock for long resident in northern Mississippi, and later forming one of the "five civilized tribes" of Oklahoma. They were foes of the French, friends of the British, and fierce fighters. They never numbered more than about 5,000, which is also their present population, although this comprises many individuals of mixed blood. (See MUSKOGIAN INDIANS.)

See Adair, *History of the American Indians* (1775).

CHICKASHA, a city of Oklahoma, U.S.A., on the Washita river, 45m. S.S.W. of Oklahoma city; the county seat of Grady county. It is on Federal highway 81, and is served by the Rock Island, the Frisco, and the Santa Fe Railways. The population in 1920 was 10,179, of whom 1,183 were negroes, and was 14,099 in 1930 by the Federal census. Chickasha is the trade centre of a cotton, corn, and wheat-growing region. The city has cotton gins and compresses, cottonseed-oil mills, and other factories, with an aggregate output valued at \$4,395,679 in 1925. Natural gas is used. The Oklahoma college for women, a State institution, was opened here in 1911. Chickasha was founded in 1892 and incorporated in 1899.

CHICKEN-POX or varicella, a specific contagious disease characterized by an eruption of vesicles in the skin. The disease usually occurs in epidemics, and the patients are generally be-

tween two and six years old. The incubation period is from ten to 15 days; there are practically no prodromal symptoms, though slight fever for some 24 hours may precede the eruption. A number of raised red papules appear on the back or chest; in from 12 to 24 hours these develop into tense vesicles filled with a clear fluid, which in another 36 hours or so becomes opalescent. During the fourth day these vesicles shrivel up, and the scabs fall off, leaving as a rule no scar. Fresh spots appear during the first three days, so that at the end of that time they can be seen in all stages of growth and decay. The eruption is most marked on the chest, but it also occurs on the face and limbs, and on the mucous membrane of the mouth and palate. The temperature begins to fall after the appearance of the rash, but may sometimes persist slightly after the disappearance of all symptoms. It rarely rises above 102° F. The disease runs a very favourable course in most cases, and after-effects are rare. One attack does not give immunity. The diet should be light, and the patient should be prevented from scratching the spots, which would lead to ulceration and scarring. After the first few days there is no necessity to confine the patient to bed. In the large majority of cases, it is easy to distinguish the disease from smallpox, but sometimes it is very difficult. The chief points in the differential diagnosis are as follows: (1) In chickenpox the rash is chiefly on the trunk, and less on the limbs and face; (2) some of the vesicles are oval, whereas in smallpox they are always hemispherical. They have not at the outset the hard shotty feeling of the more virulent disease; (3) the vesicles attain their full growth within 12 to 24 hours; (4) the rash appears "in crops"; (5) there is no prodromal period. No doubt the disease is caused by a micro-organism, but so far this has not been determined with certainty. The tendency is to ascribe it to a filter-passing virus (*q.v.*).

CHICKWEED (*Stellaria media* or *Alsine media*), an annual herb of the pink family (Caryophyllaceae), called also satin-flower, tongue-grass and winter weed. It is native to Europe and

BIRDS

Asia and widely naturalized throughout North America and other regions. The plant has weak, reclining, much-branched stems, oval or ovate leaves about 2 in. long and small white flowers. In mild climates it is found blooming throughout the year; in colder regions, as in the north-eastern United States, it withstands severe frosts and may be discovered blossoming under light snow in midwinter. Various other species of *Stellaria* and also of *Arenaria* and *Veronica* are known as chickweeds. Closely allied are the mouse-ear chickweeds (*Cerastium* sp.), various species of which are found in Great Britain, North America and other temperate regions. Most plants called chickweed, though abundant as weeds, are usually not pernicious and are readily eradicated by cultivation.
